In the summer of 1789, that season of promise and of hope, especially to a Genevese exile, Dumont suspended his labours in England in order to proceed to Paris along with his friend Duroverai, ex-attorney-general of the republic of Geneva. The object of the journey was to obtain through M. Necker, who had just returned to office, and by means of the events which were then passing in France, an unrestricted restoration of Genevese liberty, by cancelling the treaty of guarantee between France and Switzerland, which prevented the republic from enacting new laws without the consent of the parties to this treaty. The proceedings and negociations to which this mission gave rise, necessarily brought Dumont into connection with most of the leading men in the Constituent Assembly, and made him an interested spectator, sometimes even a participator, indirectly, in the events of the French revolution. The same cause also led him to renew his acquaintance with Mirabeau, whom he found occupied with his duties as a deputy, and with the composition of his journal, the *Courrier de Provence*, in which he was assisted by Duroverai, Clavière, and other Genevese patriots. For a time Dumont took an active and very efficient part in the conduct of this journal, supplying it with reports as well as original articles, and also furnishing Mirabeau with speeches to be delivered or rather read in the assembly. This is now completely established by his highly instructive and interesting posthumous work entitled *Recollections of Mirabeau.* In fact, his friend George Wilson used to relate, that one day, when they were dining together at a table d'hôte at Versailles, he saw Dumont engaged in writing the most celebrated paragraph of Mirabeau's address to the king for the removal of the troops, which was believed to have been written by the orator himself. He also reported such of Mirabeau's speeches as he did not write, and, with a disinterested sacrifice of his own reputation to the diffusion of what he considered as truth, embellished and strengthened them from his own stores, which were inexhaustible. But this co-operation, so valuable for Mirabeau, and so self-devoted on the part of Dumont, was destined soon to come to an end; for, being attacked in pamphlets as one of Mirabeau's writers, he felt hurt at the notoriety thus given to his name in connection with a man occupying Mirabeau's peculiar position, and resolved to return to England, which he accordingly did in 1791. The reputation of being a subaltern writer was, as he himself states, by no means flattering; and the credit of an influential connection with a man whose character was far from being untainted alarmed his delicacy. He saw that he had no alternative but to put an end to a copartnership of which Mirabeau was certain to reap all the advantage, whilst the odium or discredit would alone fall to the lot of Mirabeau's associate; and he acted upon this conviction with a promptitude and decision worthy of his character.

In the eventful years which followed he continued to live chiefly at Lansdowne House, or at Bowood, where the most remarkable men of Europe as well as of Britain were frequent and welcome guests. Latterly, he began to form an intimate friendship with Lord Holland, whom he had known from childhood; and he became a member of the society of familiar friends, the habitual visitors at Holland House, who, during many years, saw a succession of celebrated guests of every country, party, religion, and of every liberal profession or station, which is likely to continue unmatched until another house be found that boasts such a master. "His mind was at that time in a most perfectly mature state, with much experience of very memorable events, and familiar intercourse with the most eminent men," besides an abundant store of amusing and striking anecdotes. "He had entirely subdued the popular and declamatory propensities which characterize youthful genius, yet without being in the least degree withdrawn from the love of letters and the delights of society by those scientific pursuits which occupied a subsequent period." In 1801 he travelled over various parts of Europe with Lord Henry Petty, now Marquis of Lansdowne, and brought back a fresher acquaintance with the mental occupations of the continental nations, from whom England had for years been separated by a wider and deeper channel than that formed by the hand of nature. But Dumont had then opened a new course of more serious occupations.

"In 1801 he published the *Traités de Législation;* the first fruits of his zealous labours to give order, clearness, and vivacity, to the profound and original meditations of Bentham, hitherto praised only by a very few patient readers, and but little better known, even by name, to the English than to the European public. The extraordinary merit of these writings, manuscript and printed, chiefly attracted his mind towards them; inferior circumstances, however, contributed their part to the fervour with which he devoted himself to them. Trained in the hasty and shallow philosophy which then reigned, metaphysical principles were a novelty, in the contemplation of which he was too agreeably employed to examine the solidity of the foundation on which they rested. Wearied with the common-places of philanthropic declamation, which passed for philosophy, he ran with eagerness into the opposite extreme of new terms, dry definitions, and simple principles. The method of Bentham is undoubtedly a powerful instrument for the discovery of truth, especially in the juridical part of moral science. It is, however, a method which may become more than mischievous, by the very circumstance of its apparent perfection.

"Supposing every other objection to that system to be answered, it will still be evident that the value of its application in every particular instance must be in proportion to the exactness and completeness with which every circumstance is enumerated that can affect the determination of the question. But the enumeration is not *complete,* merely because the names of all such circumstances are enumerated. It is not thus that the philosopher proceeds in those sciences where the success is uncontested. He calculates the *degree* of every force that acts on a body; he ascertains the *proportion* of every element which goes to make up a compound; and an error in either of these respects is, in truth and effect, a want of exact and complete enumeration, which may lead to the most false results. Such mistakes in the physical sciences are easily detected. In the moral sciences it is extremely easy *to seem* to form a complete theory by such general and vague inductions, because the means of quick and palpable detection are wanting. Wherever analysis is *really* exhaustive, it is the most perfect of instruments; but where it only reaches a semblance of exactness, it produces or perpetuates error in the exact proportion of its seeming approach to truth. There is no remedy against this dangerous distemper but the habit of never forgetting that, in each case, the main question always must be, 'How much of each enumerated cause is likely to act in the instance before me?' No show of accuracy, no superiority of method, can dispense with this question, or enable any man to answer it otherwise than by approximation. But with these high and arduous matters we must not deal more largely in this place. The talent with which M. Dumont performed his task is as generally acknowledged as the perfect disinterestedness which led him to employ so much talent in expounding the opinions and enlivening the reasoning of others. It is due to him to say, that he always considered the system as a model, to be always consulted and approached, but never imposed without a cautious regard to circumstances. It must also be observed, that however entirely he adopted the speculations, delighted in the method, and even acquiesced in the language of Bentham, that for which he really felt a warm zeal, and consecrated the labour of his life, was the practical establishment of that grand reformation of law, which owes indeed much to the writings of Bentham, and to the discussions which they daily contribute to spread and keep up, but which, so far from being peculiar to him, is zealously supported by those who dissent from his moral theories, and was common to him, at least in that more obvious part of it which relates to criminal law, with the philosophers of the eighteenth century, who pursued the same object, though with less distinctness of view, less precision of language, and less knowledge of the abuses to be reformed. The mind of Dumont moved onward with that of the reformers of jurisprudence throughout Europe. He does not needlessly question the singularities of his venerable master; but his attachment was to the main stock of reforming principle. Those who knew him need not be reminded, that if his principles have any tendency to a cold and low morality, they were in that respect altogether defeated by the nature of Dumont; a man of the utmost simplicity and frankness, of a most unusually affectionate and generous disposition. A man of so much letters and wit could not have worked into his practical nature any indifference to art and accomplishment, to real learning, or to the only eloquence which deserves the name."

In 1814 the restoration of Geneva to independence induced Dumont to return to his native place, which he loved with that fervour which can only be felt by the citizen of a small republic. He was immediately chosen a member of the supreme council, and by conciliating opponents, moderating partizans, and gaining the confidence and respect of all, he became in time its chief leader and ornament, as he would have been in more conspicuous and powerful assemblies. At the time of his death he had completed a code of law, which, as chairman of a committee appointed for that purpose, it would have been his duty to present to the supreme council on its assembling after its vacation; but at the moment when he was thus about to engrave his name on the annals of his beloved country, and to honour her, by rendering her, as he hoped, an example to Europe, he was cut off in the full vigour of his faculties, and on the eve of their most conspicuous exertion. In the autumn of 1829 he undertook a tour of pleasure, or rather of relaxation, to the north of Italy, in company with one of his friends, M. Bellamy Aubert; and his family were impatiently expecting his return when they received the tidings of his death. He died at Milan, in October 1829, in the seventy-first year of his age.

Dumont was wholly untainted by political or philosophical bigotry, which has corrupted so many of those who inveigh against every form of that vice. His friends at Geneva, at Paris, or in London, were very far from sharing his peculiar opinions. Surrounded by fifty-three nephews or nieces in the first or second degree, the issue or progeny of three sisters, he treated them with a patriarchal tenderness very foreign from the scorn of some Epicureans for "the charities of father, son, and brother." In his will he leaves legacies to all; touchingly assuring them that they must not measure his kindness by his bequests. In every instance of the youngest child, he seems, with the most affectionate solicitude, to have weighed the needs and desires of each, and to have considered all their little claims as worthy of conscientious consideration. His will, which is dated in May 1826, opens with an acknowledgment worthy of him. "I begin this testamentary disposition by an act of gratitude towards God, for having blessed me with a peaceable and independent life, which has owed its chief happiness to the charm of study and the enjoyments of friendship." Such was Dumont, a pattern of wisdom and goodness, the like of which it is seldom indeed given us to contemplate, in the ordinary course of this rude and selfish world. (*Notice of M. Dumont* by Sir James Mackintosh, *Foreign Quarterly Review*, No. ix.; *Recollections of Mirabeau*, preface; *Bibliothèque Universelle*, November 1829; *Revue Encyclopédique*, vol. xiv. p. 258.) (A.)

Dumont, *John*, a well-known publicist, was born in France in the seventeenth century. He followed the profession of arms, but not obtaining promotion so rapidly as he expected, he quitted the service, and travelled through different parts of Europe. He stopped in Holland with the intention of there publishing an account of his travels. But in the interval, at the request of his bookseller, he wrote and published several pamphlets, which were eagerly sought after, by reason of the unceremonious manner in which he treated the ministry of France. This freedom having deprived him of all hope of employment in his own country, he now thought of forming a permanent establishment in that where he resided; and the knowledge which he had already acquired of the relations and interests of different nations having led him to entertain the idea of opening a course of lectures on public law, he lost no time in carrying it into effect. The project succeeded far beyond his expectations; and some useful compilations which he published about the same period made him favourably known in foreign countries. The emperor of Germany appointed him his historiographer, and some time afterwards conferred on him the title of Baron de Carlscroun. He died at Vienna in 1726, at an advanced age. Dumont wrote with facility, but his style is deficient in vigour and correctness; nevertheless, his works are esteemed as containing a great number of documents valuable for history. The following is a list of the works published by Dumont: 1. *Nouveau Voyage au Lévant*, Hague, 1694, reprinted under the title of *Voyages en France, en Italie, en Allemagne, à Malte et en Turquie*, Hague, 1699, 4 vols. 12mo; 2. *Mémoires Politiques pour servir à la parfaite intelligence de l'Histoire de la Paix de Ryswick*, Hague, 1699, 4 vols. 12mo; 3. *Mémoires sur la Guerre présente* (1700), Hague, 1703, 12mo, reprinted under the title of *Recherches modestes des Causes de la présente Guerre, en ce qui concerne les Provinces Unies*, 1713, 12mo; 4. *Récueil de Traités d'alliance, de paix, et de commerce entre les Rois, Princes, et Etats, depuis la paix de Munster*, Amsterdam, 1710, 2 vols. 12mo; 5. *Soupirs de l'Europe à la vue du projet de paix contenu dans la harangue de la reine de la Grande-Bretagne*, 1712, 12mo; 6. *Corps Universel Diplomatique du Droit des Gens, contenant un Récueil des Traités de paix, d'alliance, etc. faits en Europe, depuis Charlemagne jusqu'à présent*, Amsterdam, 1626, and following years, 8 vols. fol. continued after Dumont's death by J. Rousset; and 7. *Battailles gagnées par le Prince Eugène de Savoie*, Hague, 1723. To the *Corps Universel Diplomatique du Droit des Gens* ought to be subjoined, 1. *L'Histoire des anciens Traités jusqu'à Charlemagne*, by Barbeyrac, 1739, in 2 vols. folio; 2. *Supplément au Corps Diplomatique, avec le cérémonial des Cours de l'Europe*, collected by Dumont, and arranged by Rousset, 1739, in 3 vols. fol.; 3. *Histoire des Traités de Paix du dix-septième Siècle*, by St Priest, 1725, in 4 vols. folio. Dumont was also the author of *Lettres Historiques contenant ce qui se passe de plus important en Europe*, 12mo. This periodical, which was commenced in 1692, and two volumes of which appeared annually, Dumont conducted till 1710, from which time it was continued by Basnage, with the aid of several collaborateurs, until 1728. The earlier volumes are much esteemed. (A.)

DUMPALIS, a spacious bay on the west coast of the island of Celebes, into which flow two considerable rivers. Good anchorage is found here, and the bay is much resorted to on account of the great quantity of fish which are found in it. At the bottom of this bay is situated the town of Dumpalis, which has a considerable trade. The inland merchants bring gold dust and a particular drug, which they dispose of to the inhabitants in the town, receiving in return tobacco, opium, white cloths, iron knives, and creeses. The natives here fight with poisoned barbed arrows, blown out of black ebony tubes; and are sure to kill at the distance of twenty yards.

DUN, or Burgh, the name of an ancient species of building, of a circular form, common in the Orkney and Zetland Islands, the Hebrides, and the northern parts of Scotland. The latter term points out the founders, who at the same time bestowed on them their native name of *borg*, a Sueo-Gothic word signifying a defence or castle; and the Highlanders universally apply to these places the Celtic name *dun*, signifying a hill defended by a tower, which plainly points out their use. They are confined to the countries once subject to the crown of Norway. With few exceptions, they are built within sight of the sea, and several of them within sight of each other; so that, on a signal by fire, by flag, or by trumpet, they could give notice of approaching danger, and afford mutual support. In the Orkney and Zetland Islands they are most frequently called *wart* or *ward hills*, which shows that they were garrisoned. They had their wardmadher, or watchman, a sort of sentinel, who stood on the top, and challenged all who came in sight. The gackman was an officer of the same kind, who not only had to watch against surprise, but was also bound to give notice if he saw any ships in distress. He was allowed a large horn of generous liquor, which he had always by him, to keep up his spirits. Along the Orkney and Zetland shores they almost formed a chain, and by that means not only kept the natives in subjection, but were situated commodiously for covering the landing of their countrymen, who were perpetually roving on piratical expeditions. These towers were even made use of as state prisons; for we learn from Torfæus, that after Sueno had surprised Paul, count of Caithness, he carried him into Sutherland, and confined him there in a Norwegian tower. Out of this kingdom no buildings similar to these are to be found anywhere, except in Scandinavia. On the mountain of Swalberg in Norway is one; on the Stir-biskop, at Upsal, in Sweden, is another; and on Umsborg, in the same kingdom, is a third.

These towers vary in their inner structure, but externally they are universally the same, though some have an addition of strength on the outside. The burgh of Culswick, in Zetland, notwithstanding it is built on the top of a hill, is surrounded with a dry ditch thirteen feet broad; that of Snaburgh, in Unst, has both a wet and a dry ditch, the first being cut with great labour through the solid rock. The burgh of Moura is surrounded by a wall, now reduced to a heap of stones, and the inside is cylindrical, not tapering, as is usual with others. The burgh of Hogster, upon an isle in a loch of the same name, has also the addition of a wall; a peculiarity in a causeway to join it to the main land, and a singular internal structure. Numbers of little burghs, with single cells, are scattered about these islands, in the neighbourhood of the greater, and were probably built by the poorer sort of people, in order to enjoy their protection. A multitude of places in these islands have the addition of burgh to their names, notwithstanding there is not a vestige of a tower near them, the materials having long since been carried away and applied to various uses.

DUNABURG, a circle in the Russian government of Witebsk or Witepsk, formerly a part of Lithuania. It is bounded on the north by Livonia, on the east by Resitka, on the south-east by Wilna, and on the west by Courland. It is watered by the Düna, which is joined by other streams, and fertilizes the land, which is highly productive of rye and flax, and maintains a large stock of cattle. It contains three cities, one town, and 1078 villages, with a population in 1797 of 47,785, in 1827 of 61,500 inhabitants. The extent is 328 square miles, or 190,000 acres. The chief city, of the same name, is situated on the Düna. It was formerly fortified. It contains a Greek and a Catholic church, and 4000 inhabitants.

DUNBAR, a royal burgh, post, and market town of Scotland, in the county of Haddington, is pleasantly situated on a gentle acclivity rising from the shores of the German Ocean, near the mouth of the Frith of Forth. It consists of one main street, which runs the length of the town, with several others of smaller dimensions which intersect it. The whole has a neat and commodious appearance. Dunbar is a place of considerable antiquity, and, there is reason to believe, was built by the Picts. It originated in a castle, once of great strength and importance as a bulwark for the defence of this route into Scotland, against the invasion of the English. The site of the fortress was well chosen both for defence and convenience. The coast is here bold, and studded with rocky islets along and within the margin of the sea; and these in early times afforded room for the battlemented walls of a fort, which gradually increased by connection with the adjoining land, and with the islets by walls of great strength. It was thus admirably adapted to receive succour by sea, or allow the escape of its keepers with impunity. We find it mentioned as early as the year 856, and subsequently it stands conspicuously prominent in the various conflicts in which Scotland was embroiled. It endured several memorable sieges, the most remarkable of which was that by the English in 1337, when it was defended by a female member of the Douglas family. The place is now a total ruin. The harbour and quay of Dunbar are on a confined plan, and the usual depth of water is scarcely sufficient to float vessels of 250 or 300 tons burden. The main evil of the port arises from the existence of various craggy islets and sunken rocks near the entrance, which renders the navigation somewhat dangerous. Contiguous to the inner parts of the harbour are some large granaries and storehouses, a small graving dock, and other conveniences for shipping, which, however, exists here to a very limited extent. There is a market on Tuesday, and there are two fairs annually. Formerly Dunbar was famous for its herring fishery, but that branch of trade has now almost totally disappeared. The manufactories of the town are a soap-work, an iron foundery, and a manufactory of steam engines. There is also here some small trade in corn. The most remarkable house in Dunbar is a large plain mansion, situated at the west end of the town, the property and residence of the family of Lauderdale. In 1819 a handsome new church was erected upon the old site, which was founded in the fourteenth century. The new building is in the semi-gothic style, and is internally commodiously and elegantly fitted up. Besides this place of worship, there are two Seceder meeting-houses and a Methodist chapel. There are two public besides several private seminaries of education in the town; and the charitable and other institutions are also extensive. The town is governed by a provost and three bailies, a treasurer, town-clerk, and chamberlain, with fifteen members of council. The annual revenue of the burgh is about L.1300. Dunbar lies twenty-eight miles almost due east from Edinburgh. The population, including the country part of the parish, amounted in 1831 to 4735.

DUNBAR, WILLIAM, the most eminent of all the early Scotish poets, appears to have been born about the middle of the fifteenth century. Notwithstanding the high reputation which he enjoyed among his contemporaries, the records of his personal history and character are extremely scanty; and although he belonged to the church, his progress is not to be traced by successive preferments. He describes himself as a native of Lothian. Kennedy represents him as related to the earl of March; but this perhaps is only to be considered as a poetical fiction, introduced for the purpose of heightening his invective. His latest biographer however supposes that he may have been the grandson of Sir Patrick Dunbar of Beill in the county of Haddington, a younger son of George the tenth earl of March. "This Sir Patrick," we are informed, "signalized himself on many occasions, and was one of the hostages for James the First in 1426; and it also appears from an original charter, dated August 10th, 1440, that one of his sons was named William, who in all probability was either the father or uncle of the poet. No other person of the same baptismal name can be traced during the whole of that century; and as such names generally run in families, the circumstance of our author's alleged descent from the earls of March, in connection with his own avowal respecting his birth-place, adds some strength to the conjecture of his being the grandson of Sir Patrick Dunbar of Beill."[1] During the present age, the births, marriages, and deaths of persons possessing little property and less distinction may in a great variety of instances be very easily traced; but as the same diurnal records did not exist in the fifteenth century, it is only where names are connected with property, rank, or office, that in most cases we can succeed in an attempt to discover the outlines of private or domestic history. Neither the name nor the surname was uncommon: at that period Scotland certainly contained many Williams and many Dunbars; and if numerous instances of this combination of name and surname have not been detected, it is not difficult to assign a reason.

In the year 1477, William Dunbar of St Salvator's College took the degree of A. B. in the university of St Andrews; and as the statutes required the candidate to be of three years standing, he must have been matriculated in 1474. In 1479 he took the degree of A. M.[2] Whether this was the poet, or another individual of the same name, we have no means of ascertaining: but there is an apparent coincidence in the time; and the supposition that he studied at St Andrews, is highly probable in itself. There is likewise some reason to suppose that he studied in the university of Oxford: "Quod Dunbar at Oxenfurde," is the colophon of one of his poems; and we need scarcely remark that Oxenford was once the current name of this seat of the Muses. But it is also to be recollected that the poet might visit Oxford in some other capacity than that of a student. In his youth he appears to have been a novice of the order of St Francis. His sentiments with regard to this profession we are enabled to glean from one of his poems; and those sentiments we shall here endeavour to exhibit in plain prose. "Before the dawn of day," says Dunbar, "methought St Francis appeared to me with a religious habit in his hand, and said, go, my servant, clothe thee in these vestments, and renounce the world. But at the sight of him and his habit I was scared like one who sees a ghost. And why art thou terrified at the sight of the holy weed? St Francis, reverence attend thee, and thanks for this intended benefit; but with regard to those garments of which thou art so liberal, it has never entered into my mind to wear them: sweet confessor, take it not in evil part. In holy legends have I heard it alleged that bishops are more frequently canonized than friars; if therefore thou wouldst guide my soul towards heaven, invest me with the robes of a bishop. Had it ever been my fortune to become a friar, the season is now long past: between Berwick and Calais, in every flourishing town of the English dominions, have I made good cheer in the habit of thy order; in friar's weeds have I mounted the pulpit at Dernton and Canterbury, in them have I also crossed the sea at Dover, and instructed the inhabitants of Picardy; but this mode of life compelled me to have recourse to many a pious fraud, from the guilt of which no holy water could cleanse me. What had thus appeared to me as St Francis, was a fiend in the likeness of a friar: he vanished away with stench and fiery smoke; methought he carried one end of the house along with him, and I awoke like a wight in perplexity."[3]

From this and some other passages of his works, it is evident that Dunbar had in some degree imbibed the spirit of a reformer; and it is obvious that in all countries which have in any measure been extricated from the superstitions and delusions of the Romish church, the poets have contributed to prepare the way for the theologians. Wit and satire, when thus directed, are formidable weapons; and although ridicule is no test of truth, it has often been found a powerful instrument for exposing inveterate error. The best arguments may be employed in vain, and force commonly interposes in behalf of established opinions: but poets have in all ages claimed and exercised considerable freedom of animadversion; and, as light troops are sometimes more serviceable than the heavy-armed soldiery, the gay satirist is sometimes more successful in his attacks than the learned controversialist. Another inference to be drawn from this poem is equally obvious: as the author had preached in England and France, he must have been familiarly acquainted with the languages of both countries; or, if we suppose him to have preached at Canterbury in his native tongue, we must at least conclude that he spoke French when he instructed the inhabitants of Picardy. His travels are likewise mentioned in Kennedy's Flyting, where we must however make some allowance for satirical exaggeration.

Fra Atrik Forrest furth ward to Drumfreiss
  Thow beggit with ane pardoun in all kirkis,
Collapis, crudis, meill, grottis, gryce, and geiss,
  And undir nycht quhylis thow stall staigis and stirkis.
  Becauss that Scotland of thy begging irkis,
Thow schaipis in France to be a knycht of the feild;
Thow hes thy clamschellis, and thy burdoun keild,
  Unhonest wayis all, wolroun, that thow wirkis.[4]

Dunbar, in one of his invectives against Kennedy, has furnished us with some further information respecting his own adventures.

Or thow durst move thy mynd malitius,
  Thow saw the saill abone my heid updraw;
But Eolus full woid and Neptunus,
  Mirk and moneless, wes met with wind and waw,
  And mony hundreth myle hyne cowd us blaw
By Holland, Seland, Zetland, and Northway coist,
  In desert [place] quhair we wer famist aw;
Yit come I hame, fals baird, to lay thy boist.

After the period of his travelling noviciate, Dunbar appears in the character of a court poet, and of a candidate for preferment in the church. On one occasion he speaks of his dancing "in the quenis chalmer."

Than cam in Dunbar the makkar,
On all the flure thair was nane frakkar,
And thair he daunsit the Dirrye dantoun;
He hoppet lyk a fillie wantoun,
  For luiff of Musgraiffe, men tellis me;
He trippet quhill he tint his pantoun:
  A mirrear dance mycht na man see.

Than cam in Maistriss Musgraiffe;
Scho mycht haiff lernit all the laiffe.
Quhen I saw hir sa trimlye dance,
Hir guid convoy and countenance,
  Than, for hir saik, I wissit to be
The grytast erle or duik in France:
  A mirrear dance mycht na man see.

But neither his dancing nor his solicitations seem to have procured him any considerable preferment. From the strain of his earlier compositions, it is evident that his first hopes were sufficiently sanguine, and from that of his later compositions, that those hopes had been completely frustrated. "Why shouldst thou," says the desponding poet, "be induced to hope for preferment, when an Italian impostor finds means to thrust himself into the chair of an abbot? How the affairs of the church are managed, I know not; but assuredly its benefices are not distributed with an impartial hand. While some enjoy seven, I am not possessed of one; and some, unworthy as they are to fill a stall, would fain climb to the rank of cardinal, a bishopric being too mean an object for their ambition." He addressed some stanzas to the king when many benefices were vacant; he frequently renewed his petition, and frequently complained that his life was suffered to wear away in fruitless expectation. From the wish which he expresses "To the King, that he war Johne Thomsounis Man," it may be inferred that Queen Margaret was anxious to promote his interest: the tenor of his prayer is, that the king were more subservient to the wishes of his consort.

[2] Ibid. p. 9.
[3] Dunbar's Poems, vol. i. p. 28.
[4] Ibid. vol. ii. p. 81.

> My advocat, bayth fair and sweit,
> The hale rejosing of my spreit,
> Wald speid in to my errandis than,
> And ye war anis Johne Thomsounis man.

Whether Dunbar's advancement was in any degree retarded by his own imprudence, can only be conjectured. The clergy of that age do not appear to have been generally promoted for their piety or learning; and so very moderate was the ordinary standard of external decency, that it must only have been the most gross and flagrant profligacy that could operate as a disqualification for preferment. It must however be acknowledged that some of his strains are highly reprehensible: his compositions are occasionally tinctured with expressions which we cannot but regard as grossly indecent and profane; one of his addresses to the queen is such as might offend a modern courtezan; the more solemn observances of the church he has converted into topics of ridicule; the litanies are burlesqued in a parody which is not easily to be paralleled for its profanity. But it is more than probable that such indecent levities excited little or no disgust in his contemporaries: the age was not distinguished by any uncommon share of piety, nor had it attained to that degree of refinement which frequently secures a certain ostensible decorum, a decent appearance of virtue, where virtue itself is not to be found. To whatever cause his failure may be attributed, there is reason to suspect that he never obtained a benefice. But we learn from the public records that he was indebted to the king for a regular pension, as well as for occasional grants of money. The register of the privy seal, 15th August 1500, mentions a yearly pension of ten pounds, payable at Whitsuntide and Martinmas, to "Maister William Dunbar for all the dayis of his life," or until he should be promoted by the king to a benefice of the yearly value of forty pounds or upwards. It appears from the treasurer's accounts that the payment due at Martinmas 1501, was deferred on account of his being then in England; and it has been considered as "probable that he accompanied the ambassadors who were sent to England to conclude the negociations for the king's marriage in October 1501; and that he remained to witness the ceremony of affiancing the princess Margaret, which took place at St Paul's cross, with great solemnity and splendour, on the 25th of January 1502. Under this supposition, we can have little hesitation in believing that Dunbar was the person then styled *the Rhymer of Scotland*, who received L.6. 13s. 4d. in reward from Henry VII. on the 31st of December 1501, and a similar sum on the 7th of January following."[1] He speaks of his long and faithful services to the king, and of his having been employed in many foreign countries, in England, Ireland, France, Spain, Italy, and Germany. Mr Laing conjectures, perhaps with sufficient probability, that in these extensive peregrinations he was attached to diplomatic missions, in which his knowledge of Latin and French might be available to persons of higher rank and inferior learning.

On the 17th of March 1504, or, according to our present computation, 1505, Dunbar for the first time said mass in the king's presence; and on that occasion he received a gratuity of seven French crowns, which was a larger sum than the king usually allotted for a priest's first mass. At the term of Martinmas 1507 his pension was encreased to twenty pounds; and on the 26th of August 1510 it was encreased to eighty pounds, to be paid during his life, or until he should be promoted to a benefice of the yearly value of one hundred pounds or upwards. How long he enjoyed this pension, and whether he ever exchanged it for a benefice, no research has yet ascertained.[2] On the 9th of September 1513 the king perished at Flodden-field; and there may be some reason to apprehend that his interest was not unaffected by that fatal event. From one of his poems, written "quhen the Governour past into France," it is evident that he must have survived for several years. John duke of Albany, regent of the kingdom, sailed for France in June 1517, again in October 1522, and finally in May 1524; nor can we safely decide to which of those three voyages the poet refers. It is at least certain that he was dead in the year 1530, when Sir David Lindsay composed his Complaynt of the Papingo.[3] He describes himself as having attained to an advanced age; nor does he appear to have been so unwise as to continue his levities to the utmost verge of life; several of his poems are written in a moral and religious strain, not unbecoming an aged priest.

The poems of Dunbar are numerous and miscellaneous, but none of them extends to any considerable length. He evidently unites a brilliant imagination with an elegant taste; nor is he less conspicuous for his skill in the mechanical part of poetry. The elasticity of his mind and the versatility of his talents enabled him to arrive at eminence in different departments of composition: his allegorical poems display a rich and fertile invention; and he is equally distinguished for his powers of description and satirical humour. His diction is often remarkable for its terseness and forcible simplicity; but it is not always free from the vicious and pedantic phraseology with which the English poetry of that period is so deeply infected. Dr Nott observes that Dunbar, "a poet of a rich and lively fancy, and possessing great natural command of language," was nevertheless induced to use such pedantic diction as occurs in the opening of his beautiful moral poem, entitled the Goldyn Targe.[1] He has employed a great variety of measures; and his versification, when compared with that of his most eminent contemporaries in both kingdoms, will in general appear highly ornamented and poetical.

---

[1] Laing's Memoirs of Dunbar, p. 20.

[2] "The treasurer's accounts from the 8th of August 1513 (a month previous to the battle of Floddon) to the 25th of January 1515, which might have thrown some light on the subject, have not been preserved; and in those from that date to the 4th of September 1518 (from which time to the 5th of June 1522 there is another blank in the series) there is no mention of Dunbar's name. We cannot therefore discover the date of the last payment of his pension; but although we now lose all trace of his name, it by no means follows that his pension was entirely withdrawn: it might either have been transferred to some other branch of the royal revenue, or the poet might at last have been promoted to a benefice, when consequently his pension would cease." (Laing's Memoirs of Dunbar, p. 34.) The treasurer's accounts, 1st April 1513, mention a payment to Dunbar of so small a sum as forty-two shillings.

[3] Lindsay's Works, vol. i. p. 285.

Mr Ellis, after having quoted three of his shorter poems, subjoins the following remarks: "In these specimens we see much good sense and sound morality, expressed with force and conciseness. This indeed is Dunbar's peculiar excellence. His style, whether grave or humorous, whether simple or ornamented, is always energetic; and though all his compositions cannot be expected to possess equal merit, we seldom find in them a weak or redundant stanza."[2] The accomplished historian of English poetry likewise mentions him with no faint approbation. "I am of opinion," says Mr Warton, "that the imagination of Dunbar is not less suited to satirical than to sublime allegory; and that he is the first poet who has appeared with any degree of spirit in this way since Pierce Plowman. His Thistle and Rose and Golden Terge are generally and justly mentioned as his capital works: but the natural complexion of his genius is of the moral and didactic cast."[3] But, subjoins Mr Pinkerton, "this remark must not be taken too strictly. The Goldin Terge is moral, and so are many of his small pieces; but humour, description, allegory, great poetical genius, and a vast wealth of words, all unite to form the complexion of Dunbar's poetry. He unites in himself, and generally surpasses, the qualities of the chief old English poets; the morals and satire of Langland, Chaucer's humour, poetry, and knowledge of life, the allegory of Gower, the description of Lydgate."[4]

But the most striking proofs of his genius are certainly to be found in his two allegorical poems. The Thrissill and the Rois was composed in celebration of the nuptials of James the Fourth and Margaret Tudor; an event productive of very important consequences to both kingdoms, inasmuch as it ultimately led to that happy union which the nature of the territory and the kindred origin of the people rendered so suitable and so desirable. In the plan of this poem Dunbar displays boldness of invention and beauty of arrangement; and some particular passages are remarkable for their strength and even beauty of colouring. The Goldyn Targe, which is written in a different stanza, is another allegorical poem of nearly equal merit. The golden targe, or the shield of reason, is found an insufficient protection against the assaults of the train of love.

Some of his short poems, of a serious character, are likewise to be distinguished from the ordinary compositions of that period. The stanzas bearing the title of Learning vain without guid Lyfe possess superior merit as a moral descant. His Meditatioun in Wyntir is also to be classed among the best of his serious pieces: some of the stanzas are beautiful and pathetic; and they may all be perused with more than common interest as the solitary musings of neglected genius.

Nor are his satirical less remarkable than his serious productions. His poem entitled the Dance of the sevin Deidly Synnis presents many admirable strokes of comic and grotesque description. On the eve of Lent, the poet falls into a trance, and is presented with a glimpse of heaven and hell. Mahoun, or the devil, proclaims a dance of those wretches who have died without absolution; he commands them to prepare a mummery, and to "kast up gamountis" according to the newest French fashion. The seven Deadly Sins immediately present themselves, and are each accompanied by a select band of votaries. Pride is with evident propriety represented as leading the dance, and is dressed in the first fashion of that period: his hair is thrown back, his bonnet is placed on one side of the head, and his gown flows to his heels in ample folds.

Lat se, quoth he, now quha begynnis:
With that the fowll sevin Deidly Synnis
  Begowth to leip at anis.
And first of all in dance was Pryd,
With hair wyld back, and bonet on syd,
  Lyk to mak vaistie wanis;
And round abowt him, as a quheill,
Hang all in rumpillis to the heill
  His kethat for the nanis.
Mony prowd trumpour with him trippit;
Throw skaldand fyre ay as thay skippit,
  Thay gyrnd with hyddouss granis.

This group is succeeded by holy harlots; but Mahoun and the other fiends are not much entertained till a company of priests present their shaven crowns.

Heilie harlottis on hawtane wyiss
Come in with mony sindrie gyiss,
  Bot yit luche nevir Mahoun,
Quhill priestis come in with bair schevin nekkis:
Than all the feyndis lewche and maid gekkis,
  Black-belly and Bawsy-Broun.

Anger, who next makes his appearance, is very forcibly described in a single distich.

Than Yre come in with sturt and stryfe,
His hand wes ay upoun his knyfe.

He is attended by a band of ruffians, who follow in pairs, all equipped for war; and, as they move along, they frequently wound each other with swords and knives. The train of Anger is followed by that of Envy. He is attended by many a dissembler, flatterer, and back-biter, with "rownaris of fals lesingis," or whisperers of lies; from whom the poet cannot avoid expressing his regret that the courts of princes are never free. The next prominent figure in the dance is Covetousness, who is accompanied by catives, wretches, usurers, and hoarders of wealth. From their throats they discharge at each other torrents of molten gold; and when this ammunition is exhausted, the fiends replenish them with the same metal.

Nixt him in dans come Cuvatyce,
Rute of all evill, and grund of vyce,
  That nevir cowd be content:
Catyvis, wrechis, and ockeraris,
Hud-pykis, hurdaris, and gadderaris,
  All with that warlo went.
Out of thair throttis thay schot on udder
Hett moltin gold me thocht a fudder,
  As fyre-flawcht maist fervent;
Ay as thay tumit thame of schot,
Feyndis fild thame new up to the thrott
  With gold of allkin prent.

Sloth, after being twice called, joins unwillingly in the dance, attended by many suitable companions. He drags them along with a chain, and Belial lashes them on the loins; but their motion is nevertheless so tardy, that they are occasionally roused by being scorched in fire. The succeeding group consists of Lust and his loathsome train; he snorts like a stallion, is led by Idleness, and is attended by many foul associates who have died in their sins. When they engage in the dance, their visages become as red as the turkis stone. The foul monster Gluttony next presents himself, followed by many a drunkard and prodigal. When they become clamorous for drink, the fiends drench them with melted lead. All these terrific exhibitions might have been expected to satisfy Mahoun himself; but he is nevertheless pleased to close the entertainment with a Highland pageant.

[4] Pinkerton's List of the Scotish Poets, p. xciv.—"It is evident," says Dr Drake, "that a union of talents of this wide range must necessarily be of rare occurrence; nor can we wonder that a century should elapse before a poet in any high degree approaching the genius of Chaucer made his appearance in our island. Not indeed until Dunbar arose in the sister kingdom, had we another instance of the combination of first-rate abilities for humour and comic painting, with an equally powerful command over the higher regions of fiction and imagination." (Mornings in Spring, vol. ii. p. 4. Lond. 1828, 2 vols. 8vo.)

Than cryd Mahoun for a Heleand padyane,
Syne ran a feynd to feche Makfadyane,
  Far northwart in a nuke:
Be he the correnoch had done schout,
Ersche men so gadderit him abowt,
  In hell grit roume thay tuke.
Thae tarmegantis, with tag and tatter,
Full lowd in Ersche begowth to clatter,
  And rowp lyk revin and ruke.
The devill sa devit wes with thair yell,
That in the depest pot of hell
  He smorit thame with smuke.

Dunbar's tale of "The twa maryit Wemen and the Wedo" presents us with the only specimen of blank verse which the ancient Scotish language affords. The rhythm is of that species which the author of Piers Plowman, or some of his predecessors, borrowed from the Anglo-Saxon poets, and which appears to have derived its origin from a remote era. It was employed by the Islandic as well as by the Anglo-Saxon poets, and was constructed with some degree of nicety.[1] Their lines are generally short, and they do not rigorously confine themselves to a definite number of syllables. Here alliteration supplies the place of rhyme; the corresponding sounds are at the commencement, not at the termination of words. In two contiguous and connected lines there must be three words beginning with the same letter; and, according to the strictest rule, two of those words ought to occur in the first, and the other ought to begin the second line. It was on such a model that Dunbar and the author of Piers Plowman constructed their verses, though they have not observed all the niceties of their predecessors. In the editions, and indeed in the manuscripts of their respective poems, what is exhibited as a single verse is in reality a distich, and admits of a division without any degree of violence.

This work of Dunbar presents us with a lively though indelicate picture of ancient manners, and is a very curious relique of ancient poetry. Bishop Percy considers it as equal to one of the most humorous productions of Chaucer. The peculiarity of the versification has compelled the author to adopt many uncouth terms; and accordingly the language of this tale is more difficult to be understood, and appears more obsolete, than that of his other poems; but his shrewdness of remark and strength of description shine through the mist of obscure phraseology in which they are sometimes involved. Soon after midnight in a morning of June, the poet walks by a goodly garden, and, on hearing the sound of voices, is induced to look through the lofty hedge, when he perceives three ladies seated in a green arbour, and regaling themselves with wine: he secretly listens to their conversation, of which he professes to give a faithful report. As the wine circulates, they become more communicative, and, at the suggestion of the widow, they successively detail their experience of a married life. The sentiments which they utter, are as profligate as can well be imagined; and it is to be hoped that Dunbar did not intend this as a general representation of the ladies of his own age and nation.

Two of his satirical poems relate to a certain Italian, named John Damian, on whom James the Fourth had bestowed the abbacy of Tungland in Galloway. This adventurer appears to have been an empiric and an impostor, and to have persuaded the king that he had discovered the secret of converting baser metals into gold; nor is it surprising that Dunbar should feel some degree of indignation on seeing high preferment bestowed upon such a person. The abbot having failed to produce the promised gold, made a still more desperate attempt to maintain his reputation as an adept in science and art: he provided himself with a pair of wings, and appointed a particular day for taking his flight from the walls of Stirling castle; when the day arrived, he indeed plunged from the rampart, but instead of mounting in the air, he fell to the ground, and broke his thigh-bone. These anecdotes do not rest on the authority of a satirical poet, for this must commonly be regarded as a very dubious authority; but they are circumstantially related by Bishop Lesley in his history of that reign;[2] and the one account may so far be considered as a confirmation of the other, although the poet has added many particulars of ludicrous exaggeration. Thus, according to Dunbar's dream, he slew a friar in Lombardy, in order to obtain possession of his habit; and having fled to France, he began to practise physic, and in this way committed many new murders. The course of his adventures at length conducted him to Scotland, where he followed his leechcraft with similar success. When raised to the dignity of a prelate, he was not to be seen at mass; he did not appear at matins in his stole and scarf, but was generally to be found in his laboratory, as sooty as a blacksmith.

In lechecraft he was homocide;
He wald haf for a nycht to byd,
Ane haknay and the hurt mannis hyd,
  So mekle he was of myans.
His irnis was rude as ony rauchtir,
Quhar he leit blude it was no lauchtir,[3]
Full mony instrumentis for slauchtir
  Was in his gardyvians.

He couth gif cure of laxatif,
To gar a wicht horse want his lyf;
Quha evir assay wald, man or wyf,
  Thar hippis yeid hiddy-giddy.
His praktikis nevir war put to preif
Bot sudand deid, or gret mischeif;
He had purgacioun to mak a theif
  To de without a wedye.

Romæ, 1578, 4to.—" Eadem tempestate rex (ut hoc quoque, quod vulgo non sine risu hucusque memoratur, dicam) Italum quendam, cujus faceto sermone ingenioque delectatus erat, abbatem Tunglandiæ creavit." See likewise Lesley's History of Scotland, p. 76. Edinb. 1830, 4to.

[3] " Lors que mon frere fut en Escosse, il n'y avoit qu'un medecin, qui estoit medecin de la reyne, et de mon temps en Angleterre, il n'y avoit gueres de medecins. En Escosse un menuisier saignoit, et il y avoit des barbiers qui tondoient seulement." (Scaligerana, p. 223.)

Unto no mess preissit the prelat,
For sound of sacrying bell nor skellat;
As blak smyth brukit was his pellat,
For battiring at the study.
Thocht he come hame a newe maid channoun,
He had dispensit with matinnis cannoun;
On him come nothir stole nor fannoun,
For smwking of the smedye.

His unfortunate flight is afterwards related in a very ludicrous manner. The abbot of Tungland has furnished Dunbar with the subject of another poetical dream, which contains one passage remarkable for the strength of its satirical conception.

He sall ascend as ane horrible griphoun,
Him meit sall in the air ane scho dragoun;
Thir terrible monsteris sall togidder thrist,
And in the cludis gett the Antechrist,
Quhill all the air infeck of thair puysoun.

Many of the comic and satirical compositions of Dunbar are valuable memorials of ancient manners; and, if incapable of gratifying the reader of taste, they are at least objects of curiosity to the antiquary. Of this description are the stanzas entitled the Devill's Inquest; which strongly evince that our ancestors were grossly addicted to profane swearing. "It might," as Dr Ogden remarks, "puzzle a philosopher to trace the *love of swearing* to its original principle, and assign its place in the constitution of man." This vice is now regarded as a characteristic of the vulgar, of those who are truly vulgar in their habits and associations, whatever may be their external circumstances; but during the age of Dunbar, it seems to have been practised by all ranks and denominations. To swear like a Scot, was once a proverbial expression.[1] In this general muster of swearers, the priest takes precedence.

Me thocht as he went throw the way,
Ane priest sweirit braid, be God verey,
Quhilk at the alter ressavit he.
Thou art my clerk, the devill can say,
Renunce thy God, and cum to me.

Bishop Douglas, who certainly did not fall below the common standard of clerical decorum, has not scrupled to bedeck his compositions with abundance of oaths. The vice of profane swearing at length arrived at so scandalous a height as to require the interference of the legislature, and it was found necessary to extend the penalties to the clergy as well as the laity: by an act of Q. Mary in 1551, a "prelate of kirk," earl, or lord, was to be fined in twelve pence for the first offence committed within the next three months; different penalties were apportioned to different ranks during the first year; and for the fourth offence committed after the expiration of that period, a prelate, earl, or lord was to be banished or imprisoned for the space of a year and a day.[2]

Dunbar has left some examples of a motley species of composition, which at that period was not uncommon, and in which shreds of different languages are fantastically combined. It does not strictly come under the denomination of macaronic poetry, in which Latin are mingled with vernacular words of Latin terminations, and in which the rules of prosody are observed with at least some degree of care.[3] The earliest macaronic poet is sometimes supposed to have been Teofilo Folengo, a Benedictine monk, better known by the name of Merlinus Cocaius, who was born near Mantua in the year 1491.[4] Of his Macaronics the first edition bears the date of 1518; but during the preceding century a work had appeared under the title of "Typhis Odaxii Patavini Carmen Macaronicum de Patavinis quibusdam Arte magica delusis."[5] This model was followed by Folengo, and by Antonius Arena, or Antoine du Sablon, a French lawyer; and these two are the most celebrated poets of this fantastic school. Among the Scottish poets they have found a few imitators, particularly Drummond and Dr Geddes. Dunbar has not adhered to the same model; without regarding the rules of prosody, he intermingles Latin with Scottish lines, and produces an effect sufficiently ludicrous. Of this particular mode of composition, much earlier specimens are to be found; and Dante himself has written a *canzone* which contains a mixture of three languages, Latin, Romance, and Italian. It concludes with the following lines:

---

[1] "I have never been able to discover," says Lord Hailes, "from what cause our ancestors became so monstrously addicted to profane swearing. I remember Tom Brown some where uses, 'swear like a Scotsman,' as a proverbial expression. There certainly must be a tradition on the continent, that the inhabitants of the whole island were apt to swear in common conversation; for in Holland, the children, when they see any British people, say, 'there come the G—dams;' and the Portuguese, when they acquire a smattering of English, say, 'How do you do Jack, G— damn you?'—Queen Elizabeth was a common swearer." (Notes on Ancient Scottish Poems, p. 241.) Of the truth of one of these remarks we find a curious confirmation in the collection of Norman *chansons* subjoined to the "Vaux-de-Vire d'Olivier Basselin." Caen, 1821, 8vo.

Mauldicte en soyt trestoute la lignye!
Ils ont chargé l'artellerye sus mer,
Force bisquit et chascun ung bydon,
Et par la mer jusq' en Bisquaye aller
Pour couronner leur petit roy *Godon*.

Their little king *G— damn* was Henry the Sixth, who succeeded his father at a very tender age. The subsequent passage occurs in the works of Cretin, a Norman poet who wrote about the beginning of the sixteenth century. (Les Poesies de Guillaume Cretin, p. 168. Paris, 1723, 8vo.)

Cryant qui vive aux *Godons* d'Angleterre.

[2] Acts of the Parliaments of Scotland, vol. ii. p. 485. See likewise p. 482.

[3] Dr Good has made the following remarks in reference to the English translators of Blainville's Travels through Italy: "When they tell us that macaronic poetry, which is a mixture of Italian and Latin words, possessing a Latin termination, 'is so called from its being supposed to resemble (as being a mixture) the Italian maccheroni, these being composed of flour, cheese, and butter'—they display a woeful ignorance of the subject they attempt to elucidate. Maccherone is a term in the Italian language, significative of a blockhead, an ignoramus, or in equivalent English a *pudding-pated* fellow: and Maccheronéa (Macaronics) are obviously, therefore, burlesque imitations of the unclassical style of such writers." (Memoirs of the Rev. Alexander Geddes, LL. D. p. 256. Lond. 1803, 8vo.) The style of blockheads must generally be unclassical; but the origin of the term macaronic, as applied to this motley species of composition, is nevertheless very truly explained by the translators. For this explanation we have the authority of Folengo himself, who in the *Apologetica* prefixed to his *Opus Macaronicorum* speaks in the following manner: "Ars ista poetica nuncupatur ars macaronica, a macaronibus derivata, qui macarones sunt quoddam pulmentum, farina, caseo, botiro compaginatum, grossum, rude, et rusticanum; ideo macaronice nil nisi grassedinem, ruditatem, et vocabulazzos debet in se continere." See likewise Menage's Origini della Lingua Italiana, p. 301.

[5] Morellii Bibliotheca Pinelliana, tom. ii. p. 456. Tiraboschi, tom. vii. p. 1468. Specimens of Macaronic Poetry, p. xi. Lond. 1831, 8vo.

> Chanson, vos pogues ir per tot le mond;
> Namque locutus sum in lingua trina,
> Ut gravis mea spina
> Si saccia per lo mondo, ogn' uomo il senta:
> Forse pietà n' avrà chi mi tormenta.[1]

Skelton, the contemporary of Dunbar, has occasionally indulged in this vein of humour; and a poem of the same description occurs among the works of Dr Arbuthnot, though it has likewise been attributed to Meston. The following stanza, which forms the conclusion of Dunbar's Testament of Kennedy, may be considered as a sufficient specimen.

> I will na priestis for me sing
> Dies illa, dies iræ,[2]
> Na yit na bellis for me ring,
> Sicut semper solet fieri;
> Bot a bag-pipe to play a spryng,
> Et unum ail wosp ante me;
> In stayd of baneris for to bring
> Quatuor lagenas cervisiæ,
> Within the graif to set sic thing
> In modum crucis juxta me,
> To fle the feyndis, than hardely sing
> De terra plasmasti me.

The Flyting of Dunbar and Kennedy is an extraordinary effort of unrefined wit; and is at least sufficient to evince that the ancient Scotish tongue was not deficient in terms of abuse.[3] Lord Hailes is inclined to believe that this altercation may have been a mere play of illiberal fancy, without any real quarrel between the antagonists; and this opinion he supposes to be confirmed by the affectionate manner in which Dunbar afterwards speaks of Kennedy, and of Quintin Shaw, who in this literary duel seems to have acted the part of Kennedy's second. A similar altercation was maintained by Luigi Pulci and Matteo Franco: although for the amusement of their readers they loaded each other with the grossest abuse, yet the intimacy of their friendship is said to have continued without interruption.[4] The example of Dunbar and Kennedy was followed by James the Fifth and Sir David Lindsay, and at a later period by Montgomery and Hume. It is not to be imagined that a king and one of his courtiers were engaged in actual hostilities; and in the verses prefixed to the "Flyting betwixt Montgomery and Polwart," it is expressly stated that their altercation was not the result of a real quarrel, but of what is there described as generous emulation.

A comic tale, entitled the Freiris of Berwik, and possessing a large fund of genuine humour, seems to have been composed about the period to which our attention is now directed. Mr Pinkerton supposes it to have been written by Dunbar; but this opinion is founded on no historical evidence, nor can the internal evidence of style and manner be considered as very striking or satisfactory. "But this tale," he remarks, "cannot at any rate be above thirteen years later than Dunbar, who must have died about 1525. In 1482, Berwick was wrested from Scotland, and was ever after in the possession of the English. Now this poem speaks of all the monasteries as actually standing and flourishing while it was written; and it is well known that in 1535 Henry VIII. suppressed the lesser monasteries, and in 1539 the greater. It follows that this tale must, at all events, have been written before 1539."[5] But the poet, whoever he may have been, does not speak of the monasteries of Berwick as actually flourishing; he merely avers, that when the adventures took place, friars of the different orders were not to seek, but were dwelling in the town. It is therefore evident that this chronological argument is by no means satisfactory, and that the tale may have been written after the suppression of the English monasteries.

In the Freiris of Berwik, every reader acquainted with the poems of Allan Ramsay must recognize the original of the Monk and the Miller's Wife; and we will venture to add that the ancient is greatly superior to the modern tale. Ramsay's tale, says Lord Woodhouselee, "would of itself be his passport to immortality, as a comic poet. In this capacity he might enter the lists with Chaucer and Boccaccio, with no great risk of discomfiture. Though far their inferior in acquired address, his native strength was perhaps not widely disproportionate. Of this admirable tale, I conceive he has the merit of the invention; as the story is not to be found in any of the older writers, as Sachetti, Boccaccio, or in the *Cento Novelle antiche.* In a few circumstances there is indeed a small resemblance to the 73d of the *Cent nouvelles Nouvelles,* entitled 'L'Oiseau en la Cage,' which barely affords a presumption that Ramsay may have read that story; but in all the material circumstances, his Monk and the Miller's Wife is original. A story of more festive humour could not have been devised. The characters are sustained with consummate propriety; the manners are true to nature; and poetic justice is most strictly observed in the winding up of the piece."[6] But whatever merit this comic tale may possess, it is evident that the praise of invention does not belong to Ramsay: he had doubtless read the old Scotish tale in Bannatyne's MS. from which he transcribed other poems less capable of arresting his attention. It may scarcely be worth while to remark that the ecclesiastic whom he introduces is a secular, a parish-priest, and is therefore most improperly described as a monk. That the author of the Freiris of Berwik was likewise indebted to some preceding poet, may perhaps be considered as highly probable. In the collection of Le Grand d'Aussy there is a *fabliau* which exhibits some lineaments of the story. A poor clerk, after having studied at Paris, is returning homeward without any money in his pocket, and, on the approach of night, calls at a solitary house to entreat a lodging; but the farmer's wife very unceremoniously refuses to shelter him during the absence of her husband. As he is leaving the house, he observes a servant bringing some wine in a basket; and at the same time the maid places in a cupboard a cake which she has just made, together with a piece of fresh pork which she has taken out of the pot. A priest, wrapped in his cope, soon afterwards passes the clerk in silence, and glides into the house. The wayfaring scholar, overwhelmed with fatigue, and dying of hunger, seats himself by the road-side: there he is found by the farmer, who happens to return sooner than he is expected; and they procure admittance, after the priest has found a place of refuge in the stable, which seems to be the ground-floor under the family-dwelling. While the maid is preparing some refreshment, the *laboureur* proposes that the clerk should either sing a song or tell a story: he declares that he knows neither song nor story, but offers to relate an adventure which happened to him in the morning; and by detailing this supposed adventure, he very dexterously contrives to take his revenge on the farmer's wife. As he was traversing a wood, he saw a numerous herd of swine: some of them were large, others small, some white, others black, in a word, they were of all sizes and of all colours; but above all he admired the leader of this herd; he was fat, shining, plump—in a word, just such another as must have been that, of which Catherine lately took a morsel from the pot. The clerk prosecutes his tale with the same arch simplicity, and contrives to reveal the secret of the wine, the cake, and finally of the priest concealed in the stable. The enraged farmer, having seized a cudgel, chastises his wife; and the priest, anticipating the same discipline, makes an attempt to escape, but is unmercifully beaten, stripped naked, and in this condition turned out of the house, leaving the clerk to enjoy his joke, together with the supper and wine provided for another guest.[1] This is certainly not the identical story of the Freiris of Berwik: several of the incidents are essentially the same, but the comic scene of the pretended conjuration is wanting. Still however the Scotish tale may have been borrowed from some preceding writer. A story not materially different occurs in a French collection published in 1665, and probably in many others: the scene is laid in Granada; the unfortunate gallant is an advocate, and the pretended magician a soldier.[2] This publication is indeed of a recent date; but such a tale is too pungent and characteristic to have been devised by the obscure compiler of the collection; and it is sufficiently probable that this tale and the Freiris of Berwik were both derived from one common source.[3] Many stories, both tragic and humorous, seem to have passed with rapidity from language to language, even at a period when the different nations of Europe are generally supposed to have maintained but little intercourse with each other. In many instances it is by no means easy to account for this speedy transmission; but there were some peculiar circumstances which may be conceived to have had considerable influence; as, for example, pilgrimages to remote countries; the various missions and visitations of the clergy; the extensive journeys of merchants and their attendants; and the associations of people of different nations in the same military service, particularly in the successive crusades. The original stock of materials is much more scanty than is commonly imagined;[4] and the most distinguished writers of tales, whether in prose or verse, have very frequently contented themselves with borrowing the entire skeleton of a story, but from them it still derives its flesh and blood, its life and spirit; for in most instances the chief merit consists in the mode of telling the story, and not in the story itself. (x.)

[6] Woodhouselee's Remarks on the Genius and Writings of Ramsay (p. cvii.) prefixed to his Poems. Lond. 1800. 2 vols. 8vo.

DUNCAN, ADAM, LORD VISCOUNT, an illustrious naval commander, the second son of Alexander Duncan, of Lundie, in the county of Angus, Scotland, by Helen, daughter of Haldane of Gleneagles, in the county of Perth, was born in the month of July 1731. He received the rudiments of his education at Dundee, which is only about four miles distant from the family residence; and as his elder brother Alexander was designed for the army (in which he died lieutenant-colonel in 1771), Adam appears to have been early intended for the naval service. Accordingly, about the year 1746, he was placed under Captain Haldane, who then commanded the Shoreham frigate, and he remained two or three years with that officer. In 1749 he was entered as midshipman on board the Centurion of fifty guns, which then bore the broad pendant of Commodore Keppel, commander-in-chief on the Mediterranean station. In the beginning of 1755 he was promoted to the rank of lieutenant, and appointed to the Norwich, a fourth rate, one of the squadron under Keppel, destined to convoy to America the transports having on board the land forces commanded by General Braddock. After the debarkation of this armament he was transferred to the Centurion, where he continued until that ship returned to England; when Captain Keppel, who had for a short time commanded the Swiftsure, procured his appointment as second lieutenant of the Torbay seventy-four, to which he himself had just been appointed. Having remained on the home station for three years, he proceeded with the expedition sent against the French settlement of Goree, on the coast of Africa, and was slightly wounded in the attack of the fort, after which he became first lieutenant of the Torbay, and in this capacity returned to England. His promotion was now rapid. In September 1759 he was raised to the rank of commander; in February 1761 he was advanced to that of post-captain; and having been appointed to the Vaillant, of seventy-four guns, he again became connected in service with his original friend and patron Keppel, who, having received the command of the naval part of the expedition against Belleisle, now hoisted his broad pendant on board the Vaillant. After this affair Captain Duncan accompanied the commodore in the same ship to the attack of the Havanna, and commanded the boats in which the troops were landed, the commodore covering the disembarkation. He was afterwards very actively employed in the siege, during which he greatly distinguished himself; and when the town surrendered, he was dispatched to take possession of the Spanish ships in the harbour, being five of seventy and four of sixty guns.

[2] Les Recreations Françoises; ou nouveau Recueil de Contes à rire; pour servir de divertissement aux melancholiques, et de joyeux entretien dans les cours, les cercles, et les ruelles, part. i. p. 178. A Rouen, chés David Berthelin, dans la Cour du Palais, 1665, 2 part. 8vo.—The compiler, whose name is Nipe, professes to have gleaned from all the ancient and modern books of tales, and to have added new stories of his own invention, "plus capables de faire mourir de rire, que de faire dormir de bout."

[3] A similar incident occurs in Ravenscroft's London Cuckolds, a Comedy, act ii. sc. ii. Lond. 1683, 4to. In reference to this scene, Langbaine has remarked that "Loveday's discovering Eugenia's intrigue, and pretending to conjure for a supper, is borrowed from *Les Contes d'Ouville*, part ii. pag. 235." (Account of the English Dramatick Poets, p. 421. Lond. 1691, 8vo.)

[4] The earl of Orford professes to have derived the dreadful plot of his Mysterious Mother from an English tradition, though he afterwards discovered the supposed origin of this tradition in the novels of the queen of Navarre. A similar story, under the title of *La mayor Confusion*, occurs in the novels of Montalvan. (Sucessos y Prodigios de Amor, en ocho Novelas exemplares, f. 58. Sevilla, 1633, 4to.) The scene is laid in Madrid; and Bishop Taylor has quoted from Comitolus its exact parallel in "a strange and rare case happening in Venice." (*Ductor Dubitantium*, or the Rule of Conscience, vol i. p. 118. Lond. 1660, 2 vols. fol.)

After the capture of the Havanna, he, in the same capacity as formerly, accompanied Admiral Keppel, who had been appointed to the command on the Jamaica station, and continued with him as captain of the flag-ship until the conclusion of the war, when he returned to England.

On the recommencement of war with France in the year 1778, Captain Duncan was appointed to the Suffolk, of seventy-four guns; but before the end of the year he was removed into the Monarch, of the same rate, which, during the summer of 1779, was employed in the Channel fleet under Sir Charles Hardy, who, owing to the junction of the French and Spanish fleets, was now acting upon the defensive. Towards the close of the same year, the Monarch was one of the ships placed under the orders of Sir George Bridges Rodney, who had received instructions to force his way through all impediments into Gibraltar, and to relieve that fortress, then closely invested by a Spanish army on the land side, whilst it was blockaded on the seaward face by a flotilla sufficiently powerful to oppose the entrance of any ordinary force. In the beginning of 1780, the British fleet, when off Cape St Vincent, fell in with a Spanish squadron under Don Juan de Langara, which had been stationed there to intercept Sir George Rodney, who was supposed to have only a squadron of four sail of the line. On this occasion Captain Duncan carried the Monarch into action before any other ship of the fleet; and the St Augustin, of seventy guns, struck to him, after having been so much disabled that he was obliged to abandon her. In this action the disparity of force was great; the British fleet consisting of nineteen ships of the line, and the Spanish of only eleven ships and two frigates. Of the latter, four were taken, one was blown up, three surrendered, but afterwards got away much damaged, one was reduced almost to a wreck, and two others, together with the frigates, made their escape. Soon after his arrival in England Captain Duncan quitted the Monarch, and remained without employment until the beginning of 1780, when he was appointed to the Blenheim, of ninety guns, and continued in command of this ship during nearly the whole remainder of the war. He was constantly employed with the Channel fleet, then under the command of Earl Howe; and in September 1780, having accompanied his lordship to Gibraltar, he was appointed to lead the larboard division of the centre, or squadron of the commander-in-chief, and greatly distinguished himself in the encounter with the combined fleets of France and Spain, which took place off the entrance of the Straits. Soon after the return of the fleet to England Captain Duncan was removed into the Foudroyant, of eighty-four guns; and on the conclusion of the peace in the spring ensuing he passed into the Edgar, of seventy-four guns, one of the guard ships at Portsmouth, where, as is customary in such cases, he continued in command during the three succeeding years.

This was the last commission which he ever held as captain of a ship. In September 1789 he was promoted to the rank of rear-admiral of the blue, and in September 1790 he was made rear-admiral of the white; in February 1793 he was raised to be vice-admiral of the blue, and in April 1794 he became vice-admiral of the white; in June 1795 he was appointed admiral of the blue; and lastly, in February 1799 he received the rank of admiral of the white. But during all these periods, excepting the two last, the merit of Admiral Duncan, which was never of an obtrusive, bustling, or forward kind, seemed to have been wholly overlooked; and though he frequently solicited employment, his applications proved unavailing; in consequence of which he had it in contemplation to retire altogether from the service. This period of obscuration, however, at length passed away. In February 1795 he received an appointment, constituting him commander-in-chief of the North Seas, that is, from the North Foreland to the Ultima Thule; and he accordingly hoisted his flag on board the Prince George, of ninety-eight guns, at Chatham, but afterwards shifted it to the Venerable, of seventy-four guns, the Prince George being considered as too large for the particular quarter in which he was destined to act. Having thus attained the object of his wishes, Admiral Duncan lost no time in proceeding to carry into execution the important trust which had been confided to him; and during the whole time he held the command, he exhibited that inexhaustible patience and unwearied constancy, which, with cool judgment and determined gallantry, formed the great attributes of his professional character. In the midst of many discouragements, and on a station exposed to peculiar dangers from the shoals and sand-banks which cover the coasts of the United Provinces, and the storms with which the North Sea is frequently visited, he never shrunk from the duty which had been assigned him, or failed at any season, however tempestuous, to show his squadron off the coast which it domineered over and insulted.

For more than two years, however, nothing occurred beyond the ordinary routine of such a service; namely, occasional captures, and smart affairs with the coast batteries and the craft which took shelter under their guns. The Dutch trade, however, was nearly annihilated; their merchant-vessels were frequently captured in sight of their own ports; and the whole coast was so completely blockaded that few vessels could venture out to sea, and escape the vigilance of the British fleet or its cruisers. The Batavian fleet, though consisting of five sail of the line, six frigates, and five sloops, was also obliged to remain quietly in port, or to confine itself to short cruises, at times when want of water or provisions compelled the British ships to repair for a few days to their own coasts; and in the beginning of June 1797, it even suffered itself to be blocked up in port, although for several days Admiral Duncan's force was limited to his own ship the Venerable, of seventy-four guns, and the Adamant, of fifty. This was owing to the unhappy and dangerous spirit of mutiny which at that period had infected in succession almost every portion of the British navy. It first broke out amongst the ships at Portsmouth, then extended itself to the fleet at the Nore, and afterwards reached the North-Sea fleet, in which almost every ship hoisted the flag of defiance. At this alarming and unprecedented crisis, the conduct of Admiral Duncan proved him to be equal to the fearful exigencies of the occasion, and perhaps contributed more to the safety and true glory of the country than even his subsequent victory. Although by the secession of the disaffected ships his fleet had been so thinned that, towards the end of May 1797, he found himself at sea with only his own ship and another, he nevertheless proceeded to his usual station off the Texel,[1] where there lay at anchor the Dutch fleet of fifteen sail of the line, under the command of Vice-Admiral de Winter; and in order to detain the latter in port until a reinforcement should arrive, he caused repeated signals to be made, as if to the main body of his fleet in the offing; a stratagem which, it was supposed, had the desired effect. At length, about the middle of June, several line-of-battle ships, in detached portions, joined the British admiral, and in a short time thereafter the two fleets were again placed on an equal footing.

---

[1] On the 3d of June 1797, Admiral Duncan having assembled the officers, seamen, and marines of his own ship (the Venerable), addressed them from the quarter-deck as follows:—"My lads, I once more call you together with a sorrowful heart, from what I have lately seen of the disaffection of the fleets; I call it *disaffection*, for the crews have no *grievances*. To be deserted by my fleet in the face of an enemy, is a disgrace which I believe never before happened to a British admiral; nor could I have supposed it. My greatest comfort, under God, is, that I have been supported by the officers, seamen, and marines of this ship; for which, with a heart overflowing with gratitude, I request you to accept my sincere thanks. I flatter myself, much good may result from your example, by bringing those deluded people to a sense of the duty which they owe, not only to their king and country, but to themselves. The

But the Venerable having been upwards of eighteen weeks at sea, and during part of that time exposed to boisterous weather, was now in want of almost every description of stores; whilst others of the ships had also suffered by the recent gales, and were besides short of provisions. In these circumstances, the admiral, on the 3d of October, put into Yarmouth roads in order to refit and revictual; having left off the Dutch coast a small squadron of observation under the orders of Captain Trollope of the Russell. But early on the morning of the 9th, the Black Joke hired armed lugger showed herself at the back of Yarmouth sands with the signal for an enemy flying at her mast-head. Immediately all was bustle and preparation, and, by incredible exertions, Admiral Duncan, with eleven sail of the line, was enabled, a little before noon, to weigh and put to sea; directing his course with a fair wind right across to his old station. On the following day, the Powerful, Agincourt, and Isis joined, and on the afternoon of the 11th the advanced ships were near enough to count twenty-two sail of square-rigged vessels at anchor in the Texel. Meanwhile the admiral having received from Captain Trollope information of the course the enemy's fleet was steering, now stood along shore to the southward. At about seven on the morning of the 12th, the Russell, Adamant, and Beaulieu were descried in the south-west, bearing at their mast-heads the signal of an enemy in sight to the leeward; and about half-past eight, a strange fleet, consisting of twenty-one ships and four brigs, made its appearance in the quarter pointed out by the signal.

This was the Dutch fleet, under Vice-Admiral de Winter, consisting of four seventy-fours, seven sixty-fours, four fifty gun ships, two forty-four gun frigates, two of thirty-two guns, two corvettes, four brigs, sloops, and two adviceboats, all which had quitted the Texel at ten o'clock in the morning of the 10th, with a light breeze at east and by north. As soon as Admiral de Winter had learned that the British fleet was approaching, he recalled some ships which he had previously detached, and edged away with the wind at north-west, towards Camperdown, the appointed place of rendezvous. At daylight on the 11th, the Dutch fleet was about nine leagues off the village of Schevenningen, in loose order; but on receiving additional information, Admiral de Winter ordered his captains to their respective stations, and, to facilitate the junction of the ships to leeward, stood towards the land. On the Wykerdens bearing east, distant about four leagues, the Dutch fleet hauled to the wind on the starboard tack, and shortly afterwards discovered the British fleet in the north-north-west; upon which it put about, and as soon as a close line was formed, with frigates and other smaller vessels opposite the openings, the Dutch ships throwing their main-top-sails aback, resolutely awaited the approach of the British.

When the Dutch appeared in sight, the British fleet was, owing to the inequality of the ships in point of sailing, in very loose order. To connect the squadron, therefore, and enable the heavy-sailing ships to take their allotted stations, the admiral made the signal to shorten sail, and bring to on the starboard tack; but observing, soon afterwards, that the Dutch ships were drawing fast in shore, and finding there was no time to be lost in making the attack, he made the signals to bear up, break the enemy's line, and engage them to leeward, each ship her opponent, and also for the van to attack the enemy's rear. In his dispatch the admiral states that his signals were obeyed with the greatest promptitude; but it has been asserted that, owing to the thickness of the weather, the signal to pass through the enemy's line and engage him to leeward was not generally understood during the short time it was displayed, and that hence some uncertainty prevailed in the fleet as to the precise mode of attack. In fact, the admiral perceived that if he waited to form line, there would be no action; and, with equal judgment and boldness, he dispensed with this preliminary arrangement, and notwithstanding the still disunited state of the ships, he hurried them into action as fast as possible. The signal above mentioned was replaced by that for close action, which continued flying for an hour and a half, until it was shot away by the enemy. This signal could not possibly be mistaken.[1]

About forty minutes past twelve o'clock (12th October)

British navy has ever been the support of that liberty which has been handed down to us by our ancestors, and which, I trust, we shall maintain to the latest posterity, and that can only be done by unanimity and obedience. The ship's company, and others who have distinguished themselves by their loyalty and good order, deserve to be, and doubtless will be, the favourites of a grateful country; they will also have, from their individual feelings, a comfort which must be lasting, and not like the fleeting and false confidence of those who have swerved from their duty. It has often been my pride with you to look into the Texel, and see a foe which dreaded coming out to meet us. My pride is now humble indeed. My feelings are not easily to be expressed. Our cup has overflowed, and made us wanton. The all-wise Providence has given us this check as a warning, and I hope we shall improve by it. On Him, then, let us trust, where our only security can be found. I find there are many good men among us: for my own part, I have had full confidence of all in this ship, and once more beg to express my admiration of your conduct. May God, who has thus far conducted you, continue to do so; and may the British navy, the glory and support of our country, be restored to its wonted splendour, and be not only the bulwark of Britain, but the terror of the world. But this can only be effected by a strict adherence to our duty and obedience; and let us pray that the Almighty God may keep us in the right way of thinking. God bless you all." If this speech has but little to recommend it on the score of rhetoric, it has qualities of a nobler kind to compensate for the want of the graces of diction or oratory: it is indeed affecting and impressive in a very high degree; and it is recorded that, among the crew of the Venerable who listened to it, there was not a dry eye when the good admiral had concluded his address.

[1] The following anecdote, which is told by Admiral Sir Charles Ekins (*Naval Battles*, p. 236), shows that the instinct of true valour sometimes supplies the place of knowledge, if not of genius. Captain Inglis of the Belliqueux, sixty-four guns, owing either to long absence from active service, or an inaptitude for the subject sometimes apparent in naval officers, had neglected to make himself competently master of the signal-book; and hence, on the morning of the day of battle, when it became necessary to act with promptitude, in obedience to the signals, he found himself more puzzled than enlightened by it; so, throwing it with contempt upon the deck, he exclaimed in broad Scotch, "Damn me, up wi' the hellem, an' into the middle o't." In this manner he bravely anticipated the remedy in such cases provided by the illustrious Nelson, who, in his celebrated *Memorandum* on the eve of the battle of Trafalgar, observed, that "if a captain should be at a loss, he would not do *very wrong* if he laid his ship alongside of the enemy." In strict conformity with this doctrine, the Belliqueux was carried by her brave and honest captain into the very thickest of the fight, and got very roughly handled by the van of the enemy.

the action commenced, when Vice-Admiral Onslow in the Monarch, which led the advanced or larboard division of the British fleet, cut through the Dutch line between the Haerlem and Jupiter, pouring into each in passing a well-directed broadside; and then leaving the Haerlem to the Powerful, luffed up alongside of the Jupiter, upon which the two ships became warmly engaged. In rounding, the Monarch received the raking fire of the Monnikendam frigate and the Atalanta brig, stationed in the rear or second line. The remaining ships of the larboard division, particularly the Monmouth and Russell, were soon in action with those of the enemy's rear; amongst which the last to surrender was the Jupiter, which had been first engaged. About twenty minutes after the Monarch had passed through the Dutch line, the Venerable, frustrated in her attempt to pass astern of the Vryheid, by the promptness of the States-General in closing up the interval, ran under the stern of the latter, and soon compelled her to bear up; whilst the Triumph, the Venerable's second astern, found immediate employment for the Wassemaer, the second astern of the States-General. In the meanwhile the Venerable had ranged up close on the lee-side of the Vryheid, with which, on the opposite side, the Ardent was also warmly engaged, and, in front, the Bedford, as she cut through the enemy's line astern of the Gelykheid. The Brutus, Leyden, and Mars, not being pressed by opponents, advanced to the assistance of their admiral, and did considerable damage to the Venerable, Ardent, and other ships of the British van. At this time the Hercules, having caught fire on the poop, bore up out of the line, and came drifting near the Venerable to leeward; but although the Dutch crew contrived to extinguish the flames, yet having thrown their powder overboard, they were compelled to surrender their ship to the nearest opponent. The Venerable, which had sustained serious damage, was now obliged to haul off, and to wear round on the starboard tack. As soon as this was observed, the Triumph, which had compelled the Wassemaer to strike her colours, approached to give the finishing blow to the Vryheid, which still persisted in defending herself. At length, from the united fire of the Venerable, Triumph, Ardent, and Director, the three masts of the gallant ship fell over her side, and disabled her starboard guns; upon which the Vryheid dropped out of the line an ungovernable hulk, and then struck her colours. With the surrender of De Winter's ship the action ceased, and the British found themselves in possession of the Vryheid and Jupiter, seventy-fours; Devries, Gelykheid, Haerlem, Hercules, and Wassemaer, sixty-fours; Alkmaar and Delft, fifties; and the frigates Monnikendam and Ambuscade. The victors then hastened to secure their prizes, in order that, before night-fall, they might get clear of the shore.

This battle presented on both sides the singular spectacle of heroic courage and determined perseverance, contrasted with conduct little, if at all, short of downright cowardice or disaffection; and from first to last the opposing forces were, from various causes, pretty nearly equal. Seven Dutch line-of-battle ships quitted the action in order to return home, and nearly as many British seem scarcely to have entered it. The actual combatants, however, maintained the strife with fierce, unflinching valour; and hence the loss on both sides was proportionally severe. That of the British amounted to 203 killed and 622 wounded, while the Dutch had 540 killed and 620 wounded. During the action the latter directed their shot solely at the hulls of their adversaries, and this not until they were so near that scarcely any aim could miss; which accounts for the unusual severity of the loss sustained. On the other hand, the captured ships were all either dismasted outright, or so injured in their masts that most of these fell in the passage home; whilst as to their hulls, they were completely riddled, and only worth bringing into port as trophies of the victory.

If any proof were wanting of the superior efficacy of Admiral Duncan's mode of attack, it would be found, first, in a manly declaration made by the gallant Dutchman, and, secondly, in the practical testimony to its excellence borne by Lord Nelson. "Your not waiting to form a line," said De Winter to Admiral Duncan, "ruined me; if I had got nearer the shore, and you had attacked, I should probably have drawn both fleets on it, and it would have been a victory to me, being on my own coast." And after the battle of the Nile, Nelson, although unacquainted with Lord Duncan, wrote his lordship to tell him how he, Nelson, "had profited by his example." Besides, the British squadron was composed of very indifferent and inadequate ships; many of them having been intended for Indiamen, and otherwise ill conditioned and deficient. Had Lord Duncan's fleet been composed of the same materials as Lord St Vincent's, every Dutch ship would have been taken; and had all the ships imitated the example of their chief, the same result must have followed. Few people are aware of the merits of the chief on that memorable day. When the action ceased, the ships were in nine fathoms water, within five miles of a lee shore, with every appearance of the gale which followed; a situation as critical as it is possible to imagine. And it should also be recollected, that when the Dutch put to sea, the admiral had only been two days in port, after a blockade of nineteen weeks. It was the opinion of Lord Duncan that, upon such occasions, the commander-in-chief should hoist his flag on board of a frigate; and he stated that, if he should ever fight another battle, he would certainly do so. He was often heard to declare that, if his flag had been flying on board of a frigate in this action, not one of the Dutch fleet would have escaped.

No victory was ever more seasonable, none more gratifying to the nation, than that of Camperdown. Politicians beheld in it the annihilation of the marine of Holland, long our most formidable rival on the seas; naval men admired the promptitude, decision, and address displayed by the admiral in approaching to the attack, in circumstances altogether unprecedented; and the people at large were transported with admiration and delight, though they did not very well know why. Hence the honours which were immediately conferred on the admiral received the approbation of all parties. On the 21st of October he was created Lord Viscount Duncan of Camperdown, and Baron Duncan of Lundie, in the county of Angus; his second in command, Vice-Admiral Onslow, was made a baronet; gold medals were struck and presented to the flag officers and captains; and the thanks of parliament were voted to the fleet. A pension of L.2000 per annum was likewise granted to Lord Duncan for his own life, with remainder to the two next heirs of the peerage.

After the victory of Camperdown, Lord Duncan continued to hold the same command until the commencement of 1800, when, being advanced in years, he withdrew from the service, and passed the remainder of his life in retirement, chiefly at his patrimonial residence. At the period of his death, however, which happened on the 4th August 1804, he was, we believe, about to be recalled into active service; and he had signified his determination to obey the call of his country at a season of unexampled difficulty and danger, when his career was terminated for ever by a sudden and fatal illness. In June 1777 he had married Henrietta, daughter of the Right Honourable Robert Dundas, lord president of the Court of Session in Scotland, and father of Lord Viscount Melville; and by this lady he had a large family. Lord Duncan was succeeded in his titles and estate by his second son, Robert, now Earl of Camperdown.

Lord Duncan was a man as remarkable in appearance as he was distinguished for character and worth. In person he was of a colossal and athletic form, six feet four inches in height, erect in his carriage, and, notwithstanding his great size, graceful in his movements, with a countenance strongly expressive of intelligence and benevolence. In him, singular meekness of disposition, extreme modesty in all that concerned himself, and the most unaffected dignity of mind, were blended with genuine spirit, high professional genius, vigorous and active wisdom, singular alacrity and ability for performing great achievements, and a decided indifference about success, excepting in as far as it might contribute to advance the good of his country. His private character was that of a man most exemplary in all the social relations of life; an affectionate relative, a steady friend, and a pattern of virtue and true piety. Lord Duncan was a most sincere and devout Christian, nor did he ever lose sight of the duties belonging to that character. He encouraged religion by his own practice, and, wherever he held a command, caused the public observance of it to be maintained. Immediately after the victory, which has immortalized his name, was decided, he ordered the crew of his ship to be called together, and, at their head, upon his bended knees, in the presence of the Dutch admiral, who was greatly affected with the scene, he solemnly offered up praise and thanksgiving to the God of battles for having crowned with success the arms of his country. In like manner, when all eyes were upon him, in the cathedral of St Paul's, on the day of general thanksgiving, in December following, his demeanour was so humble and devout, as not only to increase the admiration which his services had otherwise gained him, but to impress on all present a sense of the real dignity as well as importance of religion. In a word, Lord Duncan afforded a conspicuous instance of the truth of the remark, that piety and true courage are naturally allied, and that death loses its terrors to those who have placed their hope beyond it. (Collins's *Peerage*, by Sir E. Brydes; *Naval Chronicle*, vol. iv.; Charnock's *Biographia Navalis;* Chalmers's *Biographical Dictionary*, art. *Duncan;* James's *Naval History of Great Britain*, vol. ii.; Ekins's *Naval Battles*, p. 231.) (A.)

DUNCAN'S SUGAR LOAF, an island in the Mergui Archipelago, of a triangular form, about six miles in circuit, near the south coast of the island of St Matthew. Lat. 9. 42. N.

DUNCHURCH, a small town of the hundred of Knightlow, in the county of Warwick, eighty-one miles from London. It is situated on what was once a heath, celebrated for an ancient legend of the Dun Cow, some of whose bones are still affirmed to be preserved there. The inhabitants amounted in 1801 to 1087, in 1811 to 789, in 1821 to 947, and in 1831 to 1029.

DUNCOMBE, WILLIAM, younger, son of John Duncombe of Stocks, in Hertfordshire, was born in London in January 1690. He published in 1722 a translation of Racine's *Athalie*, which was well received by the public, and has gone through three editions. In 1724 he was editor of the works of Mr Needler; in 1735, of the poems of his deceased brother-in-law Mr Hughes, two vols. 12mo; in 1737, of the miscellanies of his younger brother Mr Jabez Hughes, for the benefit of his widow, in one volume 8vo; and in 1745, of the works of the Rev. Samuel Say, in one vol. 4to. In 1726 he married the only sister of Mr John Hughes, whom he long survived. In 1734 his tragedy of Lucius Junius Brutus was acted at Drury Lane Theatre. It was published in 1735, and again in 1747. The works of Horace, in English verse, by several hands, were published by him in two vols. 8vo, with notes, in 1757; and a second edition, in four vols. 12mo, with many imitations, appeared in 1762. In 1763 he collected and republished "Seven Sermons by Archbishop Herring, on public occasions, with a biographical preface." He died in February 1769, at the age of eighty.

DUNDALK, a seaport town of Ireland, in the county of Louth, about forty miles from Dublin. It is a large and thriving town, with a wide street nearly a mile in length, and a very fine market-house near the entrance from Dublin. In the reign of Edward II. it was a royal city, the last we read of where a monarch of all Ireland was actually crowned and resided. It was formerly very strong, and had many towers and small castles in it. The bay has good moorings at all times, and from four to above eight fathoms water, with very good landmarks, either for bringing up to or making the harbour. In crossing the bar at high water, or ordinary neap tides, there is from fifteen to eighteen feet water. The manufacture of cambric was established in this town in 1737, for the first time in Ireland, and it has ever since flourished. Muslin is also made here, and corn is exported. It is the assize town of the county. The population amounts to 10,078.

DUNDAS, HENRY, VISCOUNT MELVILLE, a late eminent British statesman, was born about the year 1741. He was a younger son of the Right Honourable Robert Dundas, lord president of the Court of Session in Scotland, by Miss Gordon, a daughter of Sir William Gordon of Gordonston, Bart. He was educated at the High School and University of Edinburgh, and having been brought up to the profession of the law, was admitted a member of the Faculty of Advocates in the year 1763. He soon distinguished himself at the bar, and rapidly attained to extensive practice. The first promotion he obtained was the situation of one of the assessors to the magistrates of Edinburgh; after which he became successively an advocate-depute and solicitor-general. In 1775, when Sir James Montgomery was appointed lord chief baron, Mr Dundas succeeded him in the office of lord advocate, which situation he continued to occupy until 1783. In the month of March 1777, he was appointed joint keeper of the Signet for Scotland.

From the period of his appointment to the office of lord advocate, Mr Dundas in a great measure abandoned the ordinary practice of the bar, and devoted himself to public business. In 1774 he became a member of parliament, having been elected representative for the county of Edinburgh. Some years afterwards he resigned the representation of the county in favour of the late lord chief baron of the Court of Exchequer, and was chosen member for the city of Edinburgh, which he continued to represent until his advancement to the peerage. Although originally returned to parliament in opposition to the ministerial interest, he soon joined the party in power, and became a strenuous supporter of Lord North's measures during the American war. He frequently spoke in the House of Commons, and, notwithstanding the disadvantages of an ungraceful manner and a provincial dialect, he was always listened to with great attention, on account of the clearness of his statements and the weight of his arguments.

In the year 1782, Mr Dundas was admitted a member of the Privy Council, and appointed treasurer of the navy, under the administration of the late Marquis of Lansdowne, then Earl of Shelburne; and he continued to fill that office, and to support the measures of government, until the dissolution of that ministry. During the short coalition administration he was out of place, and made a conspicuous figure in opposing the memorable East India bill, a measure which occasioned the overthrow of the ruling party. Upon that occasion he displayed a knowledge of the affairs of the East India Company, which was evidently the result of much study and laborious investigation. In the month of December 1783, when Mr Pitt became prime minister, Mr Dundas was restored to the same office which he had previously held; and was appointed president of the board of control, under the new East India system. In 1791 he became a member of the cabinet, in consequence of his appointment to the office of principal secretary of state for the home department. The duties of this office he discharged with energy and ability. The volunteer system, which, undoubtedly, contributed much to rouse the spirit of the country during a period of peculiar difficulty and danger, has been ascribed to Mr Dundas. On the accession of the Duke of Portland to the administration of Mr Pitt, he resigned the home department, and became secretary at war. At this time he also held the offices of lord privy seal, and governor of the Bank of Scotland, and enjoyed an extent of patronage in his native country, which has seldom or never fallen to the share of any individual, and has been considered by many as more exclusive than can be safely confided to the hands of any one man. For many years he was the intimate friend and coadjutor of Mr Pitt, and took a leading part in all the important measures of his administration. The details of these measures, and Lord Melville's conduct in regard to them, belong to history. In the present article we must restrict ourselves to a general outline of the events of his life, and a short summary of the leading traits of his character.

Upon the resignation of Mr Pitt in 1801, Mr Dundas also resigned his political offices; and in 1802, under the administration of Mr Addington, afterwards Lord Sidmouth, he was elevated to the peerage, by the titles of Viscount Melville and Baron Dunira. The last public situation which he held in the government was that of first lord of the admiralty, to which he was appointed, on Mr Pitt's return to power, in the room of Lord St Vincent. It was in his administration of the affairs of the naval department that his lordship incurred that irregularity relative to the balances of public money remaining in his hands, which produced his celebrated impeachment. We conceive it unnecessary to dwell upon the proceedings of that well-known trial. It is sufficient to say that the House of Lords finally acquitted him of all the charges brought forward in the articles of impeachment exhibited by the Commons; but he had previously resigned all his offices in the administration.

Subsequently to his acquittal, Lord Melville was restored to his seat in the privy council; but he did not return to office. He sometimes took a share in the debates in the House of Lords; and, in 1810, he brought forward a motion, the object of which was to recommend the employment of armed troop-ships, instead of hired transports, for the accommodation of such troops as it might be found expedient to embark in furtherance of the public service. But the greater part of his time was spent in Scotland, where he died suddenly, at the house of his nephew, the Right Honourable Robert Dundas, lord chief baron of the Exchequer, on the 27th of May 1811, at the age of seventy-one. He appeared in his usual health for some time preceding, and his death is supposed to have been hastened by the affection he felt for the loss of his old and valued friend the Lord President Blair, who died a few days before.

In his person Lord Melville was tall, stout, and well formed. In public life he was principally distinguished by his great capacity for business, by the unwearied attention which he paid to the details of all official measures, and by the manliness and decision of his conduct. For many years, as we have already observed, he was the steady friend and firm supporter of the measures of Mr Pitt, to whom he proved a very powerful auxiliary. Whilst he held the offices of treasurer of the navy, and first lord of the admiralty, his exertions are admitted to have been attended with great advantage to the public service. He devised several improvements in the details of that department, which have been found of great utility; and, in particular, the regulations with regard to the payment of seamen's wages, transmission of letters, and other matters connected with that branch of the public service, contributed much to the comfort of that class of men, and are highly honourable to the character of their author. In parliament he was a clear, acute, and argumentative speaker. His eloquence, however, was that of a man possessed of strong natural talents, wholly unadorned by literary taste or acquirements; and his speeches produced their effect from the solidity of his arguments, and the fearlessness with which he delivered his opinions, not from any powers of oratory or graces of style. The ornamental parts of eloquence, indeed, he seemed to despise, and was satisfied to bring his audience at once to the object he had in view. Political power was his passion, and the bustle of official life was the element in which he loved to move.

In private life his lordship was a most agreeable companion; easy, frank, and convivial; careless of money, even to a fault; always disposed to do kind offices; affectionate in his domestic relations, and greatly beloved by the numerous circle of his friends.

Lord Melville was twice married: first, to Miss Rannie, daughter of Captain Rannie of Melville, by whom he had one son, Robert, now Lord Melville; and three daughters. His second wife was Lady Jean Hope, sister of the late Earl of Hopetoun, by whom he left no issue.

Although not, strictly speaking, a literary man, Lord Melville is the author of several pamphlets on political subjects, which are distinguished by his usual sense and knowledge of business. These are, 1. *The Substance of a Speech in the House of Commons, on the British Government and Trade in the East Indies, April* 23, 1793. London, 1813, 8vo. 2. *Letter to the Chairman of the Court of Directors of the East India Company, upon an open Trade to India.* London, 1813, 8vo. 3. *Letters to the Right Honourable Spencer Percival, relative to the Establishment of a Naval Arsenal at Northfleet.* London, 1810, 4to.

DUNDEE, a seaport town in Forfarshire, situated on the north bank of the river Tay, about twelve miles from its mouth. It is forty-two miles from Edinburgh, twenty-two miles from Perth, and eighteen south-west from Arbroath, being in latitude 56. 2. 23. north, and longitude 3. 2. 55. west. The history of Scotland narrates many sackings and burnings of this town. The last of these was by General Monck; and such was its wealth at that time, that every soldier in Monck's army is said to have received L.60 sterling as his share of the plunder. Dundee was erected into a royal burgh by William the Lion in 1165. The town is governed by a provost, four bailies, a dean of guild, and thirteen councillors, and sends a member to parliament. In 1831 the government, at the solicitation of the inhabitants, granted them a resident sheriff-substitute. The market-place, or High Street, is a spacious square, 360 feet long by 100 broad, from which diverge the Nethergate, Seagate, Overgate, and Murraygate, the principal streets, which run from east to west, parallel to the river. These streets, till within the last forty years, formed the chief part of the town; and the access from it to the harbour being through narrow lanes, it had a very hampered and crowded appearance. This defect has been remedied by the opening up of several spacious streets

Dundee.

leading from north to south, with houses built in a modern style. Castle Street leads from the south-east end of the High Street to the new docks on the south, and contains, among other neat buildings, an episcopal chapel and a theatre. At the south-east corner is an elegant building in the Grecian style, erected for an exchange and reading-room. On the south side of the market-place or square stands the town-hall, surmounted by a steeple, and having piazzas below; it was built in 1743. Opposite to this building is a spacious new street, named Reform Street; at the north end of which, and fronting the town-hall, an elegant edifice has lately been erected, in the Grecian style of architecture, for an academy and public schools. At the east end of the High Street, and rather obstructing the entrance to the Murraygate, stands the trades' hall, a plain edifice, with pilasters of the Ionic order, the principal apartment of which is used as a reading-room, and it contains, besides, apartments for each of the nine incorporated trades. A little to the west of the High Street is the Nethergate, a spacious and well-built street, in which are the remains of an old cathedral, containing four places of worship, one of which, the most entire, is built in the finest Gothic style, the groining of the arches being much admired. This structure is said to have been originally built by David earl of Huntingdon as far back as the year 1185. On the west end of these churches stands a magnificent Gothic tower 156 feet high. There are several other churches and chapels connected with the establishment, besides two episcopal chapels, and various other places of worship for dissenters, who form no inconsiderable part of the population. Among the public institutions may be mentioned a lunatic asylum, an infirmary, a dispensary for out-patients, and an orphan institution; a chamber of commerce, the society of writers, incorporated by royal charter, and a mechanics' institution. Dundee has four joint-stock banking establishments, viz. the Dundee Bank, the Union Bank, the New Bank, and the Commercial Bank. Besides these, there are agencies for the British Linen Company, the National Bank of Scotland, and the Bank of Scotland. There is a native establishment for fire insurance, and one for sea insurance. There are two weekly newspapers published in the place. The trade of Dundee has long been extensive, and it has rapidly increased of late years. Its manufactures are chiefly brown and bleached linens for the home and foreign market, great quantities of which are exported directly to North and South America. It also carries on a great trade to the Baltic, and has a number of vessels employed in the whale fishery. In the London trade, besides a number of sailing smacks, there are two splendid steam-vessels, having each two engines of 125 horse power. A railway was opened some years ago between Dundee and Newtyle, a village in Strathmore, about ten miles distant, which lays open the traffic of that extensive agricultural district. This undertaking has been attended with considerable expense, from the nature of the ground. It crosses the Law of Dundee, a high hill, by means of an inclined plane and tunnel, and the Siedlaw range of hills by an inclined plane at Balbeuchly. Two locomotive engines of ten horse power each are employed on it. The difficulties encountered in crossing the mountainous ridges being overcome, it is about to be extended to Coupar Angus, Glammis, Forfar, &c. Among the undertakings either in progress or in prospect may be mentioned a new jail and bridewell, a new custom-house, and an establishment for supplying water to the town. The tonnage of the port in 1832 amounted to 32,868 tons, which employed about 3500 seamen. Its imports in flax and hemp in 1832 amounted to 21,967 tons. There are in the town and neighbourhood about fifty spinning-mills, all worked by steam; and the steam power employed in the different establishments exceeds 1400 horse power. There are several extensive iron founderies, and establishments for the manufacture of steam-engines and machinery. The grandest and most important feature, however, of Dundee is its harbour, upon which nearly L.200,000 has been expended. It consists of magnificent wet docks and a number of spacious quays, graving dock, &c. spreading along the margin of the Tay, and terminated on the west by the Craig Pier, which is exclusively appropriated to the use of the ferry, on which two twin steam-boats are employed, of a construction which admits of horses and carriages being transported across the river, which is here two miles broad, without unloosing the horses from the vehicles to which they are attached. The increase of the trade of Dundee within the last eighteen years has been in a greater ratio than that of any other place in the empire, if we except Liverpool and Glasgow, as will be seen from the following statement: In 1815 it had 157 vessels, registering 15,275 tons; in 1832 it had 274 vessels, registering 32,867 tons. In 1815 sixty-six vessels entered inwards with cargoes from foreign ports, registering 10,620; in 1832 there were 307 vessels, registering 46,539 tons, being an increase of 241 vessels, and four times the amount of tonnage. In 1815 three vessels cleared outwards with cargoes for foreign ports, registering 679 tons; in 1832, fifty-six vessels cleared outwards for foreign ports, registering 11,159 tons, being an increase of fifty-three vessels, and more than sixteen times the amount of tonnage. The population of Dundee in 1821 was 30,575, and by the census of 1831 it was 45,355, exclusive of the seamen belonging to the port. It is now understood to exceed 50,000. This town has become the principal seat of the linen trade of Great Britain, and the great emporium of flax and hemp.

Dunfermline.

DUNFERMLINE, a royal burgh of Scotland, situated in the western district of the county of Fife, fifteen miles north-west of Edinburgh, in longitude 3. 27. 11. west, latitude 56. 5. 3. north. The town is built on an extensive eminence, having a pretty steep and uniform declivity towards the south, and likewise declining into a ravine on the west, which divides the more ancient part of the town from the extensive and extending suburb of Pittencrieff. This ravine is crossed by an earthen mound, on which an excellent street has been built, which equals the second-rate streets of the metropolis, and exceeds in its uniformity, and the splendid appearance of its shops, the principal streets of most country towns. The town is situated about 270 feet above the level of the sea, and about two miles and a half distant from Limekilns, the nearest place on the coast. It may be described as consisting of one principal thoroughfare, stretching from east to west, near the top of the eminence on which the town is built, which is intersected at right angles by streets running up and down the hill, terminating in a plain both at the top and bottom. From its elevated situation, the prospect all around is very extensive. Seen from the south or west, the town has a very noble appearance, principally from its irregular outline, and the many prominent objects, such as steeples and public buildings, with which the whole is adorned; and it is here and there interspersed with gardens and trees, which give it a very pleasing and picturesque appearance, flanked as it is on the east and west by the extensive policies of Viewfield and Pittencrieff. The building most worthy of notice is the Abbey Church, which has been erected on the site of the Church of the Holy Trinity, built by Malcolm Canmore, about the middle of the eleventh century; which was demolished by Edward I. on the 10th February 1304, and subsequently at the Reformation, on the 28th of March 1560. However, at the latter period, the nave escaped

Dunfermline.

destruction, and was used as a place of worship till September 1821, when the new church was opened for divine service. It is a splendid edifice, in the most elegant Gothic style. Over the centre of the cross is erected a square tower ninety feet high, terminating in a flat roof, round the four sides of which, in open hewn work, are the words "King Robert the Bruce," in capital letters four feet in height, surmounted by royal crowns and lofty pinnacles on the four corners, which give an elegant and appropriate finish to the whole. The old church forms a very fine entrance to the new; and, were a little expense laid out in some small repairs, it might be rendered still more impressive. It is of various orders of architecture, accordant with the different ages in which it has been altered and repaired. The interior of the new Abbey Church is even more elegant than its exterior. Its tower and galleries are supported by magnificent pillars, moulded on the solid mason-work with Roman cement, into small columns, which form the aggregate pillar, the capitals of which are adorned with exquisite imitations of foliage. The ribs of the arches composing the different roofs and the central ornaments are in the purest style, and, seen from any point, the effect of the whole is at once magnificent and pleasing. Exactly below the pulpit, which is of wainscot, and in the Gothic style, lie the remains of Robert Bruce; and in the north transept lie seven other kings, two queens, and numbers of the nobility. Besides the old church, all that now remains of the ancient buildings is the south-west wall of the palace, which hangs on the brink of a deep hollow, through which runs a small stream. A building over a gate, probably the principal entrance to the palace yard, the south wall of the Refectory or Fraters Hall, and a large window of elegant workmanship, form the whole antiquities of the abbey and palace. There is likewise some slight traces of Malcolm Ceanmore's tower, which formed the original nucleus of the town. The Guildhall, which was erected in 1808, is a superb edifice of the Grecian order, having a spire a hundred and thirty-two feet in height. It consists of a large hall intended for meetings of guildry; the chamber is occupied as a reading-room, and the rest of the building is fitted up as a hotel. The town-house is a narrow building, with a prison above. The council hall is adorned with some good paintings, and the whole is surmounted by a spire. The Bank of Scotland is an elegant building in the Abbey Park, surrounded with an extensive policy. The High School is a beautiful building in the Grecian style, and is taught by a rector and usher; the Commercial Academy is in the form of a villa, where the several branches of education are taught by two independent teachers, with assistants. A handsome new row of houses has been erected at the eastern entrance to the town.

The linen trade is of considerable antiquity in Dunfermline; it began originally with ticks and checks. The first table-linen manufactured here was a kind called huckabuck; this was followed in course of time by damask, the richest and most ingenious kind of table-linen, which has been for the last century improving in quality and pattern, and is still continuing to be improved. The value of table-linens and covers annually manufactured here is estimated at about L.200,000. Another important branch of industry is the spinning of yarns and threads; there are eight large spinning mills, at some of which the very finest quality of yarns is manufactured.

This town is remarkable as being the theatre in which the principal dissents from the established church have taken their rise; namely, the Seceders under Ralph Erskine, and the Relief under George Gillespie.

The population of the parish in 1821 was 13,690, and of the town 8041; in 1831 the former was 17,068, and the latter 10,624.

DUNGALLY, a town on the western coast of the island of Celebes, situated on the south point of land which forms one side of Parlow Bay, which affords good anchorage. It is defended by a fort, and carries on a considerable trade.

DUNGANNON, a town of Ireland, in the county of Tyrone, situated on a hill. It is of some extent, and contains a charter school liberally endowed, also barracks for a troop of horse. This place is said to have been the chief residence of the O'Neils, monarchs of Ulster. There are coal mines in the neighbourhood of the town. It lies seventy-two miles north-west of Dublin. The population amounts to 3515.

DUNGARVON, a town of Ireland, in the county of Waterford, situated on the south side of a bay of the same name. The principal article of export is potatoes. This place is much resorted to in summer for sea-bathing. It lies twenty-two miles west-south-west of Waterford, and a hundred miles south-south-west of Dublin. The population amounts to 6519.

DUNGYE, a town of Hindustan, province of Bahar, district of Shahabad, sixty-eight miles south-west from Patna. Long. 84. 17. E. Lat. 24. 55. N.

DUNKELD, a town of Scotland, in the county of Perth, situated on the northern bank of the river Tay, in a truly romantic spot, embosomed among lofty crags, now almost wholly covered with wood. It is the chief market-town of the Central Highlands. The immediate vicinity has been greatly improved by the Dukes of Atholl, particularly by the last, under whom much was done not merely to beautify his own residence, but also to enrich the scenery which encloses Dunkeld, particularly on the north. He also commenced building a new mansion, or rather palace, on an extensive and magnificent scale; but the building was interrupted by his death, and has not yet, it seems, been resumed.

Dunkeld is of great antiquity. It was the capital of ancient Caledonia. About the dawn of Christianity, a Pictish king made it the seat of religion, by erecting there a monastery of Culdees, which king David I., in 1130, converted into a cathedral, and it ranked as the first in Scotland. Since the Reformation it has in a great measure fallen into ruins. The choir, however, is still entire, and converted into the parish church, which has of late been very elegantly fitted up. On the north side of the choir is the charter-house, built by Bishop Lauder in 1469, the vault of which is now used as the burying-place of the Atholl family. In the porch of the present church is the tomb of Alexander Stuart, earl of Buchan, third son of Robert II., but better known by the name of *The Wolfe of Badenoch*, who died in 1394. The seat of the Atholl family, when the new building is completed, will be one of the finest in the kingdom. There is, almost right opposite, a cascade, on the water of Bran, which, in its way from the western hills, forms a considerable fall called the *Rumbling Brig*, from a narrow bridge made by the fall of two rocks across the stream. The pencil of Rosa never delineated a wilder or more striking scene. The stream has a second fall, which, but for the other, would be deemed superb. Sir James Galloway, master of requests to James VI. and to Charles I. was created Lord Dunkeld in 1645; but his grandson James was attainted at the Revolution, and having died at the beginning of last century, the title became extinct. Besides the parish church, there are two dissenting meeting-houses in Dunkeld. The village has five fairs annually. The population amounted in 1821 to 1915, and in 1831 to 1471.

DUNKIRK, an arrondissement of the department of the

North, in France, extending over 310 square miles, divided into seven cantons, and these subdivided into fifty-nine communes, containing 86,580 inhabitants.

Dunkirk, a city in the department of the North, in France, at the end of a harbour which is nearly dry at low water. It was formerly more flourishing than it is at present, and once created such apprehensions on the part of England, that in several treaties the demolition of the fortifications was stipulated. It now contains 1800 houses and 24,600 inhabitants. There are still the rudiments of a naval arsenal; and it has some trade, and shipping employed in the whale fishery.

DUNMOW, Great, a market-town of the hundred of the same name, in the county of Essex, thirty-seven miles from London, and situated on the river Roding. It is a town of very ancient date, supposed to be the Cæsaromagus of the Romans, and where remains of the road to Colchester, constructed by that people, are still visible. It is governed by a corporation. The market is held on Saturday. The inhabitants amounted in 1801 to 1828, in 1811 to 2015, in 1821 to 2409, and in 1831 to 2462. Near to it is Little Dunmow, remarkable for the ancient right which a happy couple have to demand a flitch of bacon at the end of a year from their marriage.

DUNNING, John, Lord Ashburton, a celebrated English counsellor, was the second son of Mr John Dunning of Ashburton, Devonshire, an attorney. He was born at Ashburton, on the 18th of October 1731, and was educated at the free grammar school of his native place, where he soon distinguished himself by his proficiency in classical literature as well as the mathematics. On leaving school he was taken into his father's office, where he remained until the age of nineteen, when he was sent to the Temple. After he came to the bar he got very slowly into practice. In the year 1762 he was employed to draw up *A Defence of the United Company of Merchants of England trading to the East Indies, and their Servants, particularly those at Bengal, against the Complaints of the Dutch East India Company to his Majesty on that subject;* which was considered as a masterpiece of language and reasoning, and from which he derived not only immediate profit, but such a large share of reputation as secured him extensive practice in his profession.

In 1763 he distinguished himself as counsel in the memorable proceedings in the case of Wilkes, and his professional business, from that period, gradually increased to such an extent that, in 1776, he is said to have been in the receipt of nearly L.10,000 per annum. In 1766 he was chosen recorder of Bristol, and on the 23d of December 1767 he was appointed to the office of solicitor-general, which he held until the month of May 1770, when he retired, along with his friend Lord Shelburne. In 1771 he was presented with the freedom of the city of London. From this period he was considered as a regular member of the opposition party, and distinguished himself by many able speeches in parliament. He was first chosen member for Calne in 1768, and continued to represent that borough until he was promoted to the peerage. In 1782, when the Marquis of Rockingham became prime minister, Mr Dunning was appointed chancellor of the duchy of Lancaster; and about the same time he was advanced to the peerage, by the title of Lord Ashburton. He died while on a visit to Exmouth, on the 18th of August 1783.

The person of Lord Ashburton was by no means agreeable or prepossessing. He was a short, thick man, with a sallow countenance, a constant shake of the head, and a hectic cough, which frequently interrupted the stream of his eloquence. His oratory, however, was at once fluent, elegant, and argumentative, and he possessed a sound knowledge of the laws, and of the theory of our constitution. His language was pure and classical, yet peculiar to himself, and he had a great fund of wit and humour. His disposition was originally timid, but this defect he overcame by practice, as he became more familiar with forensic habits. Of the great extent of his practice some notion may be formed from the fortune he left behind him, which was all earned by his own exertions, and amounted to no less a sum than L.180,000.

Sir William Jones has pronounced a splendid eulogium on the character of Lord Ashburton. "His language," says that accomplished scholar, "was always pure, always elegant; and the best words dropped easily from his lips into the best places, with a fluency at all times astonishing, and, when he had perfect health, really melodious. His style of speaking consisted of all the turns, oppositions, and figures, which the old rhetoricians taught, and which Cicero frequently practised, but which the austere and solemn spirit of Demosthenes refused to adopt from his first master, and seldom admitted into his orations, political or forensic. That faculty, however, in which no mortal ever surpassed him, and which all found irresistible, was his wit. This relieved the weary, calmed the resentful, and animated the drowsy; this drew smiles even from such as were the objects of it; scattered flowers over a desert; and, like sun-beams sparkling on a lake, gave spirit and vivacity to the dullest and least interesting cause. He was endued with an intellect sedate yet penetrating, clear yet profound, subtle yet strong. His knowledge, too, was equal to his imagination, and his memory to his knowledge."

Besides the *Answer to the Dutch Memorial*, Lord Ashburton is supposed to have assisted in writing a pamphlet on the law of libel, and to have been the author of *A Letter to the Proprietors of East India Stock, on the subject of Lord Clive's Jaghire, occasioned by his Lordship's Letter on that Subject*, 1764, 8vo. His lordship was at one time suspected of being the author of the celebrated *Letters of Junius*. (See Chalmers's *Biog. Dict.*, and Sir W. Jones's *Works*, vol. iv.)

DUNS, John, a schoolman of the highest reputation, is said to have been born in the year 1274, but the place of his birth has been long and much disputed. Dempster has asserted the claims of Scotland by twelve arguments;[1] but a less formidable number might perhaps have been sufficient. The designation *Scotus*, which is commonly added to his name, evinces him to have been a native either of Scotland or of Ireland; and the pretensions of the latter country cannot be supported by the authority of a single early writer. Wadding and other Irish authors who claim him as their countryman, persuade themselves that he was born at *Dunum*, or Downpatrick, and must thence have derived the name of Duns;[2] but this is obviously a mere conjecture, unsupported by tradition, and carrying with it no great plausibility. Leland claims him as an Englishman, on the authority of certain manuscript copies of his works, preserved in the library of Merton College, and bearing a colophon which describes him as born at the village of Dunstane in the county of Northumberland.[3] But if this had been the place of his birth, his surname ought to have been Dunstane. It apparently belongs to the class of local surnames, or those derived from places of birth or habitation; and we have little or no hesitation in supposing him to have been a native of Dunse in the county of Berwick. This surname is still to be found in Scotland. He is mentioned as a native of Scotland by Trithemius,[1] and likewise by Paulus Jovius, Sixtus Senensis, Possevin, and many other writers of various countries. We are told that when a boy he became accidentally known to two Franciscan friars, who, finding him to be a youth of very extraordinary capacity, took him to their convent at Newcastle, and afterwards persuaded him to become one of their fraternity. From thence he was sent to Oxford, where he became a fellow of Merton College, and professor of divinity; but it appears that he had likewise studied at Paris. His lectures were frequented by a prodigious concourse of students. His fame was now become so universal, that the general of his order removed him to Paris, that the students of that university might also have the benefit of his lectures. He went to Paris in the year 1304, where he is said to have been honoured first with the degree of bachelor, then of doctor of divinity, and in 1307 to have been appointed regent of the divinity schools; but as he had taught divinity at Oxford, he must previously have taken at least one degree in that faculty. During his residence at Paris, arose the famous controversy about the immaculate conception of the Virgin Mary. Albertus Magnus maintained that she was born in original sin. Scotus advanced two hundred arguments in support of the contrary opinion, and convinced the university of Paris that she was really conceived immaculate. This important nonsense however continued to be disputed till the year 1496, after the council of Basel, when the university of Paris made a decree, that no student who did not believe the immaculate conception should be admitted to a degree. Duns had not been above a year at Paris, when the same general of the Franciscans ordered him to remove to Cologne, where he was received with great pomp and ceremony by the magistrates and nobles of that city, and where he died of an apoplexy soon after his arrival, in the year 1308, in the thirty-fourth year of his age. Some writers have reported that he was buried in an epileptic fit, and that, upon removing his bones, he appeared to have turned himself in his coffin. The genius of this renowned schoolman, who obtained the appellation of *Doctor Subtilis*, or the Subtle Doctor, reflects no inconsiderable lustre on the nation to which he belonged: he maintained a reputation almost unrivalled till the scholastic theology and scholastic philosophy were finally exploded. His followers, who were called Scotists, opposed the opinions of the Thomists, or followers of St Thomas Aquinas. An edition of his works, accompanied by a life of the author by Luke Wadding, was published at Lyon in twelve volumes folio.

DUNSE, a market-town of Scotland, in the district of Merse, Berwickshire. It is situated on a rising ground in the middle of the shire, and though not the county town, is by far the largest and most respectable place in Berwickshire. It is a burgh of barony, and is governed by a bailie. The town is of great antiquity, and was frequently destroyed in the Border wars. As seen from any point around, Dunse has the appearance of a city, and on closer inspection it is found to possess a respectable proportion of good houses. In the market-place stands the town-house, an elegant modern building, in the Gothic style. Besides a parish church, Dunse possesses two Seceder meeting-houses and a Relief chapel. There is here a weekly market, and four fairs for sheep and three for horses and cattle annually. Dunse is considered as the birthplace of the famous John Duns Scotus. A mile south of the town is a well of mineral water, which is a powerful chalybeate. The population in 1821 amounted to 3773, and in 1831 to 3469.

DUNSTABLE, a market-town in the hundred of Manshead, in the county of Bedford, thirty-three miles from London. This neighbourhood was celebrated formerly for the size of its larks, and for the great number of straw and chip hats made by the females, a trade which is still extensively carried on. It was a Roman station, the Mageovinium of Antoninus. There is here a weekly market, which is held on Saturday. The inhabitants amounted in 1801 to 1296, in 1811 to 1616, in 1821 to 1831, and in 1831 to 2117.

DUNSTAN, Saint, a famous archbishop of Canterbury. He was descended from a noble family in Wessex, and educated in the abbey of Glastonbury, where he studied so hard that it threw him into a violent fever, which brought him to the very point of death. When the whole family were standing about his bed, dissolved in tears, and expecting every moment to see him expire, an angel came from heaven in a dreadful storm, and gave him a medicine which restored him to perfect health in a moment. Dunstan immediately started from his bed, and ran with all his speed towards the church to return thanks for his recovery; but the devil met him by the way, surrounded by a great multitude of black dogs, and endeavoured to obstruct his passage. This would have frightened ordinary boys, but it had no effect whatever upon Dunstan, who, having pronounced a sacred name, and brandished his stick, put the devil and all his dogs to flight. The church doors being shut, an angel took him up in his arms, conveyed him through an opening in the roof, and set him softly down on the floor, where he performed his devotions. After his recovery, he pursued his studies with the greatest ardour, and soon became a perfect master in philosophy, divinity, and music; painting, writing, and sculpture; besides working in gold, silver, brass, iron, and other metals. Whilst still young he entered into holy orders, and was introduced by his uncle Athelm, archbishop of Canterbury, to King Athelstan, who, being charmed with his person and accomplishments, retained him at his court, and employed him in many great affairs. At leisure hours he used to entertain the king and his courtiers with playing on the harp, or some other musical instrument; and now and then, by way of variety, he wrought a miracle, which gained him great admiration. But his old enemy the devil was much offended at this, and prompted some envious courtiers to persuade the king that his favourite was a magician; a story which that prince too readily believed. Dunstan, however, having discovered by the king's countenance that he had lost his favour, resolved to resign rather than be turned out, and accordingly retired from court to another uncle, who was Bishop of Winchester. This good prelate prevailed upon his nephew to forsake the world and become a monk; after which he retired to a little cell built against the church wall of Glastonbury. Here he slept, studied, prayed, meditated, and sometimes amused himself with forging several useful things in brass and in iron. One evening as he was working very busily at his forge, the devil, putting on the appearance of a man, thrust his head in at the window of his cell, and asked him to make something or other for him. Dunstan was so intent upon his work that he made no answer, upon which the devil began to swear and to talk obscenely. This betrayed the lurking fiend. But the holy blacksmith was prepared for all casualties; so putting up a secret ejaculation, he pulled his tongs, which were red hot, out of the fire, and seizing the devil by the nose, squeezed the Satanic organ of smell with a degree of energy which caused his infernal majesty to bellow and scold at such a rate that he awakened and terrified all the people for many miles around. Thus far the monkish legend.

---

[1] Trithemius de Scriptoribus Ecclesiasticis, f. 76. a. Basil. 1494, fol.

However ridiculous these fictions may seem, they served, in those times of ignorance, to procure Dunstan a reputation which has been confirmed by the authority of several succeeding historians. It appears that this extraordinary person was called to court in 941, by King Edmund, who bestowed upon him the rich abbey of Glastonbury, which for his sake he honoured with many peculiar privileges. Dunstan enjoyed in a very high degree the favour of this prince during his short reign of six years; but he stood much higher in the grace of his brother and successor King Edred, to whom he was confessor, chief confidant, and prime minister. During this period of court favour he employed all his influence in promoting the interest of the monks of the Benedictine order, to which he belonged, and of which he was a most active and zealous patron. Having the treasures of these two princes, especially of the last, at his command, he lavished them away in building and endowing monasteries for these monks, because almost all the old monasteries were in the possession of secular canons; and not contented with this, he persuaded Edred, who was a bigoted valetudinary, to bestow, by his last will, such immense treasures on the churches and monasteries, that the crown was stripped of its most valuable possessions, and left in a state of indigence. This conduct of Dunstan, whilst he was in power, rendered him very odious to Edwy, who succeeded his uncle Edred in 955; and his rude behaviour to the king himself, and his beloved queen Elgiva, raised the resentment of that prince to such a height that he deprived Dunstan of all his preferments, and drove him into exile. The banishment of Dunstan, the great patron, or, as Malmsbury calls him, the prince of monks, was a severe blow to that order, who were in consequence expelled from several monasteries. But their sufferings were not of long continuance; for Edgar, the younger brother of Edwy, having raised a successful rebellion against his brother, and usurped all his dominions on the north side of the Thames, recalled Dunstan, and in 957 conferred on him the bishopric of Worcester. From this moment he was the chief confidant and prime minister of King Edgar, who in 959 became sole monarch of England, by the death of his elder brother Edwy. In the following year Dunstan was raised to the archiepiscopal see of Canterbury; and being thus possessed of the primacy and assured of the royal support and assistance, he prepared to execute the grand design which he had long meditated, of compelling the secular canons to put away their wives and become monks, or, in case of resistance on their part, of driving them out, and introducing Benedictine monks in their stead. With this view he procured the promotion of Oswald to the see of Worcester, and of Ethelwald to that of Winchester, two prelates who were monks themselves, and animated with the most ardent zeal for the advancement of their order; and these three great champions of monachism found means, by their arts and intrigues, in the course of a few years, to fill no fewer than forty-eight monasteries with Benedictines. But on the death of Edgar in 975 they received a check. The sufferings of the persecuted canons had excited much compassion, and many of the nobility, who had been overawed by the power and zeal of the late king, now espoused their cause and promoted their restoration. Elferc duke of Mercia drove the monks by force out of all the monasteries in that extensive province, and brought back the canons, with their wives and children; whilst Elfwin duke of East Anglia, and Brithnot duke of Essex, raised troops to protect the monks in these countries. In order to allay these commotions, several councils were summoned, and Dunstan was so hard pushed by the secular canons and their friends, that he was obliged to practise some of his holy stratagems; but finally, by dint of miracles, he overcame all opposition.

St Dunstan died in 988, in the sixty-fourth year of his age, having held the bishopric of London, together with the archbishopric of Canterbury, about twenty-seven years. As this prelate was the great restorer and promoter of the monastic institutions, the grateful monks, who were almost the only historians of those dark ages, have loaded him with the most extravagant praises, and represented him as the greatest wonder-worker and highest favourite of heaven that ever lived.

DUNSTER, a borough-town in the hundred of Carhampton, in Somersetshire, 163 miles from London. It is situated in a beautiful vale at the foot of the Quartoch Hills, about one mile from the Bristol Channel. It has ceased to send members to parliament for many years. The market is held on Friday. The inhabitants amounted in 1801 to 772, in 1811 to 868, in 1821 to 895, and in 1831 to 983.

DUNTEEWARAH, a town of Hindustan, belonging to independent chiefs, in the province of Gujerat. Long. 72. 45. E. Lat. 24. 55. N.

DUNUM, a Celtic term, denoting a hill or eminence, and often concurring to form the names of towns, as well as to indicate their elevated situation as places of strength or citadels; hills or eminences being adapted to such structures. See DUN.

DUNWICH, a small borough-town of the hundred of Blything, in Suffolk, once a city, and remarkable only from having sent two members to parliament, but it is now disfranchised. The inhabitants amounted in 1801 to 184, in 1811 to 208, in 1821 to 200, and in 1831 to 232.

DUPIN, LOUIS ELLIES, doctor of the Sorbonne, and professor of philosophy in the Royal College, one of the greatest critics of his time, especially in ecclesiastical matters, was born at Paris in 1657. When he published the first volume of his *Bibliothèque Universelle des Auteurs Ecclésiastiques*, in 1686, the liberty with which he treated some ecclesiastical writers gave so much offence that M. de Harlay, archbishop of Paris, obliged Dupin to retract many of his propositions, and besides suppressed the work. Nevertheless he was suffered to continue it, by altering the title from *Bibliothèque Universelle* to *Bibliothèque Nouvelle*. This great undertaking, continued in successive volumes till it reached as many as fifty-eight, though sufficient to occupy the life of an ordinary man, did not prevent M. Dupin from obliging the world with other works. He was a man of prodigious reading, and had an easy, happy way of writing, with an uncommon talent for analyzing the works of an author; a quality which renders his *Bibliothèque* so valuable. M. Dupin was banished for a time from his chair in the Royal College, to Chatelherault, on account of the famous *Cas de Conscience*, but he was afterwards restored, and died in 1719.

DUPINASCHA, a city of Turkey in Europe, in the province of Kostendill. It stands at the foot of a mountain of its own name, which is watered by the Isker, and contains about 6000 inhabitants, chiefly employed in the iron mines of the mountains near them.

DUPLE, among mathematicians, denotes the ratio of 2 to 1. Thus the ratio of 8 to 4 is duple, or as 2 to 1.

Sub-duple ratio is just the reverse of the former, or as 1 to 2. Thus the ratio of 4 to 8, or 6 to 12, is sub-duple, or as 1 to 2.

DUPLICATE, among lawyers, denotes a copy of any deed, writing, or account. It is also used for the second letters-patent granted by the Lord Chancellor in a case wherein he had done the same before. A second letter written and sent to the same party, and of the same tenor as a former one, from fear of the first miscarrying, is called a *duplicate.*

DUPLICATION, in general, signifies the doubling of any thing, or multiplying it by 2; also the folding of any thing back again on itself.

DUPLICATURE, among anatomists, is a term used to denote the folds of any membrane or vessel. Thus we say the *duplicatures of the intestines, peritonæum,* and the like.

DUPONDIUS, in *Antiquity,* a weight of two pounds, or money of the value of two asses. See As.

Since the as at first weighed a pondo or libra, the dupondius must have weighed two; and hence the name. Though the weight of the as was afterwards diminished, and consequently that of the dupondius, yet they still retained the denomination. See Pound and Libra.

DUPPA, Brian, a learned English bishop, was born in 1589, at Lewisham, in Kent, of which place his father was then vicar. In 1634 he was constituted chancellor of the church at Sarum, and soon afterwards made chaplain to Charles I. He was appointed tutor to Charles prince of Wales, and his brother James duke of York; and about the same time nominated to the bishopric of Chichester. In 1641 he was translated to the see of Salisbury, but received no benefit from this preferment, owing to the suppression of episcopacy. Charles I. held him in high esteem, and is said to have derived assistance from him in composing the Εικων Βασιλικη. After the restoration he was made bishop of Winchester, and lord high almoner. He died at Richmond in 1662, aged seventy-three.

DUPPAU, or Daupow, a town in the circle of Ellbogen, in the Austrian kingdom of Bohemia. It is situated in a vale watered by the river Auboche, and has a castle, a monastery, and about 1200 inhabitants, chiefly employed in the cloth manufacture.

DUPUIS, Charles Francis, an eminent French writer, and member of the Institute, was born of poor parents, at Trye-Château, between Gisors and Chaumont, on the 26th of October 1742. His father, who was a teacher, instructed him in mathematics and land-surveying. The Duke de la Rochefoucault, who accidentally became acquainted with the youth, took him under his protection, and gave him a bursary or exhibition in the College of Harcourt.

Dupuis made such rapid progress in his studies, that, at the age of twenty-four, he was appointed professor of rhetoric at the college of Lisieux. In his hours of leisure he applied himself to the study of the law, and on the 11th of August 1770 he was admitted an advocate before the parliament. He was charged by the rector of the university with the task of delivering the customary discourse at the distribution of prizes; and he was also employed in the name of the university to compose the funeral oration of the Empress Maria Theresa of Austria. These two works having been printed, were admired on account of their elegant latinity, and laid the foundation of the author's fame as a writer.

The mathematics having been the object of his early studies, he now devoted his more serious attention to that science; and for some years he attended the astronomical lectures of Lalande, with whom he formed an intimate friendship. In 1778 he constructed a telegraph on the principle suggested by Amontons; and he succeeded so well, that he was enabled to correspond with his friend M. Fortin, who, from the village of Bagneux, where he had a country seat, observed with a telescope the signals made by Dupuis at Belleville, and returned his answer on the following day. In this manner they continued to correspond every year, during the fine season, from 1778 to the commencement of the Revolution. Dupuis then destroyed his machine, lest it should render him suspected in those dangerous times.

Much about the same time, Dupuis formed his ingenious theory with respect to the origin of the Greek months. In the course of his investigations upon this subject, he composed a long memoir on the constellations. He had been struck with the singularity of the figures by which the groups of stars called constellations were represented on the most ancient planispheres; and had also remarked that these groups did not present to the eye any form analogous to their representations. Hence he concluded, that the real configurations of these constellations, or asterisms, could not have been the origin of the figures and of the names which had been given to them from the highest antiquity. Dupuis attempted to resolve this enigma, in so far at least as related to the constellations of the zodiac. He conceived that this representation of the heavens during the course of the year must have some reference to the state of the earth, and to the labours of agriculture at the time, and in the country, in which these signs had been invented; so that the zodiac was, for the people who invented it, a sort of calendar at once astronomical and rural. It seemed only necessary, therefore, to discover the clime and the period in which the constellation of *Capricorn* must have arisen with the sun on the day of the summer solstice, and the vernal equinox must have occurred under *Libra.* It appeared to Dupuis that this clime was Egypt, and that the perfect correspondence between the signs and their significations had existed in that country for a period of between fifteen and sixteen thousand years before the present time; that it had existed only there; and that this harmony had been disturbed by the effect of the precession of the equinoxes. He therefore ascribed the invention of the signs of the zodiac to the people who then inhabited Upper Egypt or Ethiopia. This was the basis on which Dupuis established his mythological system, and endeavoured to explain the curious subject of fabulous history, and the whole system of the theogony and theology of the ancients.

Persuaded of the importance of his discoveries, which, however, were by no means entirely original, Dupuis published several detached parts of his system in the *Journal des Savants* for the months of June, October, and December 1777, and of February 1781, which he afterwards collected and published, first in Lalande's *Astronomy,* and then in a separate volume in 4to, 1781, under the title of *Memoire sur l' Origine des Constellations, et sur l'Explication de la Fable par l'Astronomie.* The theory propounded in this memoir was refuted by M. Bailly, in the fifth volume of his *History of Astronomy;* but, at the same time, with a just acknowledgment of the erudition and ingenuity exhibited by the author.

Condorcet proposed Dupuis to Frederick the Great of Prussia as a fit person to succeed Thiebault in the professorship of literature at Berlin; and Dupuis had accepted the invitation, when the death of the king put an end to the engagement. The chair of humanity in the college of France having at the same time become vacant by the death of M. Bejot, it was conferred on Dupuis; and in 1788 he became a member of the Academy of Inscriptions. He now resigned his professorship at Lisieux, and was appointed by the administrators of the department of Paris one of the four commissioners of public instruction.

At the commencement of the revolutionary troubles Dupuis sought an asylum at Evreux; and having been chosen a member of the national convention by the department of the Seine and Oise, he distinguished himself by the moderation of his speeches and public conduct. In the third year of the republic he was elected secretary to the assembly, and in the fourth he was chosen a member of the council of Five Hundred. After the memorable 18th of *Brumaire* he was elected by the department of the Seine and Oise a member of the legislative body, of which he became the president. He was afterwards proposed as a candidate for the senate; and here terminated his political career.

In 1794 he published his large work, entitled *Origine de tous les Cultes, ou la Religion Universelle*, 3 vols. 4to, with an atlas, or 12 vols. 12mo. This work excited considerable sensation at first; it gave umbrage to many, was attacked and defended with warmth, at length ceased to be read, and fell into utter neglect. In 1798 he published an abridgment of this work in one volume 8vo, which met with no better success. Another abridgment of the same work, executed upon a much more methodical plan, was published by M. de Tracy. The other works of Dupuis consist of two memoirs on the *Pelasgi*, inserted in the *Memoirs of the Institute;* a memoir *On the Zodiac of Tentyra*, published in the *Revue Philosophique* for the month of May 1806; and a *Mémoire Explicatif du Zodiaque Chronologique et Mythologique*, published the same year, in one volume 4to. It was from the perusal of the poem of *Nonnus*, which he once thought of translating into French, and of which a fragment was printed in the *Nouvel Almanach des Muses* for the year 1805, that Dupuis caught the first idea of his astronomical system.

Dupuis died at Is-sur-Til, on the 29th of September 1809, leaving behind him several manuscripts on subjects connected with the works which he had published during his life. He was a member of the legion of honour; and his character was that of an honest man and a paradoxical writer. He was born poor, and never acquired any fortune. M. Dacier, secretary to the third class of the Institute, delivered his *Eloge;* and an historical account of his life and writings was published by his widow. (See also *Biographie Universelle.*)

DUQUELLA, a province of Morocco, about seventy-five miles long and sixty broad. It is chiefly remarkable in an agricultural point of view for the production of a species of water melon, which grows to a prodigious size. Grain is also raised, but not in such quantities as in some other parts of the empire. Goats are bred in immense numbers, and their skins form one of the principal articles of export from Mogadore. Honey and wax are in great abundance. The inhabitants are industrious, and much inclined to commerce.

DURADSCH, the ancient Dyrrachium, a sea-port in Greece, in the country of the Arnauts. It is the see of a Greek archbishop and of a Catholic bishop, is fortified, and contains 5000 inhabitants. There is a good harbour, whence both commerce and piracy have long been carried on. The air is most unwholesome.

DURAKAH, a small island in the Red Sea, about sixteen miles from the coast of Arabia. Long. 41. 31. E. Lat. 16. 48. N.

DURANDUS, William, one of the most learned lawyers of the thirteenth century, was born at Puimoission, in Provence. He was a pupil of Henry of Susa, and taught canon law at Modena. He was afterwards made chaplain and auditor of the sacred palace, legate of Gregory X. at the council of Lyons, and bishop of Mende in 1286. His works are, 1. *Speculum Juris*, Rome, 1474, folio, whence he derived the name of *Speculator;* 2. *Rationale Divinorum Officiorum*, Mentz, 1459, folio, scarce; 3. *Repertorium Juris*, Venice, 1496, folio.

DURANGO, a town of Spain, in the province of Biscay. It stands twenty miles south-east of Bilboa, on one of those numerous streams which, when united, form its river. It contains 2800 inhabitants. Manufactories of iron and steel goods are carried on here.

Durango, or New Biscay, an intendancy of Mexico, in North America. According to Humboldt, it extends from long. 104. 40. to 110. 0. W. and from lat. 23. 55. to 29. 5. N.[1] It is bounded on the west by Sonora; on the east it touches on San Luis Potosi; and towards the north and east, for upwards of 200 leagues, it borders on an uncultivated country, inhabited by warlike and independent Indians. It comprehends the northern extremity of the great table-land of Anahuac. Its length from north to south, from the celebrated mines of Guarisamey to the mountains of Carçay, is 232 leagues. Its breadth is very unequal, and near Parrel is scarcely fifty-eight leagues. Its extent of surface is greater than that of the united kingdom of Great Britain and Ireland; and yet its total population, according to Humboldt, was in 1803 rather less than 160,000. Of these, Major Pike thinks, three twentieths might be European whites, five twentieths Creoles, five twentieths Mestizoes and half-castes, and seven twentieths Indians. It comprises, besides the city of Durango, six towns (villas), 199 villages (pueblos), seventy-five parishes (paroquias), 152 haciencias, thirty-seven missions, and 400 cottages (ranchos).

The climate of this intendancy is stated by Major Pike to be dry, and the heat, at that period of the year which precedes the rainy season, to be very great. The rains commence in June, and continue by light showers till September. During the remainder of the year there falls neither rain nor snow to moisten the earth, and the atmosphere becomes highly electrified. The agricultural produce consists of wheat, maize, rice, oats, cotton, flax, indigo, and the fruit of the vine. To the north of Chihuahua, about thirty miles to the right of the main road, there is some pine timber. In one place, near a spring, Major Pike noticed a solitary walnut tree; and in all the small streams there are, he says, shrubby cotton trees. "With these few exceptions, the whole province is a naked, barren plain, which presents to the eye an arid unproductive soil; and, more especially in the neighbourhood of mines, even the herbage appears to be poisoned by the qualities of the land." New Biscay trades with the southern provinces, and also with New Mexico and Sonora, furnishing to the more populous parts of the kingdom a great number of horses, mules, beeves, sheep, and goats, in return for dry goods, European furniture, ammunition, books, and other articles, which are brought from the capital on mules. "Some individuals make large fortunes by being the carriers from Mexico to Chihuahua, the freight being eight dollars per cent.; and they generally put 300 lb. on each mule. The merchants make their remittances twice a year, in bullion. Goods sell at Chihuahua about 200 per cent. higher than the prices in the seaport towns of the Atlantic. This was in 1807. Horses then averaged six dollars; some, however, fetched a hundred dollars; and trained mules twenty dollars. Rice sold for four dollars the hundredweight. They manufacture some few arms, blankets, stamped leather, embroidery, coarse cotton and woollen cloths, and a species of carpeting." This traveller concludes his statistical account of

---

[1] According to Major Pike, a more recent traveller in these parts, it is situated between long. 105. and 111. W. and lat. 24. and 33. N. He gives its length from north-west to south-east at 600 miles, its greatest breadth at 400, and its population at 200,000.

Durango.

the province by stating, that law here is merely a shadow, the only laws that can be said to be in force being the military and the ecclesiastical; that the corruption of morals is general, this being the natural concomitant of a great degree of luxury among the rich, and of misery among the poor; and that the Roman Catholic religion is in full force, but the inferior clergy are much dissatisfied.

There are no slaves in this province, nor, according to Humboldt, a single tributary individual; and "all the inhabitants, are either white, or consider themselves as such." Major Pike explains the state of things more specifically. Except the Apadus, who inhabit the Bolson de Mapimi, there are, he says, no uncivilized tribes in this province. "The Christian Indians are so incorporated amongst the lower grades of Mestizoes, that it is scarcely possible to draw the line of distinction, except at the ranchos of some nobleman or large landholder, where they are in a state of vassalage. This class of people laid a conspiracy, which was so well concerted as to baffle the research of the Spaniards for a length of time, and to occasion them the loss of several hundreds of the inhabitants. The Indians used to go out from their villages in small parties; in a short time a part would return with a report that they had been attacked by the Indians. The Spaniards would immediately send out a detachment in pursuit, when they were led into an ambuscade, and every soul cut off. They pursued this course so long that the whole province became alarmed at the rapid manner in which their enemies multiplied; but some circumstances leading to a suspicion, they made use of the superstition of these people for their ruin. Some officers disguised themselves like friars, and went round amongst the Indians, pretending to be possessed of the spirit of prophecy. They preached up to them that the day was approaching when a general deliverance from the Spanish tyranny was about to take place, and invited the Indians to join with them in promoting the work of God. The poor creatures came forward, and in their confessions stated the great hand that had already been put to the work. After they had ascertained the nature and extent of the conspiracy, and obtained a body of troops, they commenced the execution, and put to death about four hundred of them. This struck terror and dismay throughout the Indian villages, and they durst not rise to support their freedom and independence."

Durango or Guadiana, the principal city, is the residence of the intendant and of a bishop. It is situated in the most southern part of the province, in long. 107. W. and lat. 25. N., at 170 leagues distance in a straight line from the city of Mexico, and 289 leagues from the town of Santa Fe, in New Mexico. The elevation of the town above the sea level is 6800 feet. There are frequent falls of snow, and the thermometer descends to 14° Fahrenheit below the freezing point. The city was founded in 1559. The population in 1803 was 12,000, but Major Pike makes it 40,000. He also states that the city is infested in a very remarkable manner by scorpions. "They come out of the walls and crevices in May, and continue for about a fortnight in such numbers that the inhabitants never walk in their houses after dark without a light, and always shift or examine the bed-clothes and beat the curtains previously to going to rest, after which the curtains are secured under the bed."

In the midst of a very level plain, between this city, the plantations Del Ojo and Del Chorro, and the town of Nombre de Dios, which lies in the road to the famous mines of Sombrereto, there arises a singular group of rocks, of a very grotesque form, covered with scoria, called La Breña. They extend twelve leagues from north to south, and rise from east to west, and appear to be a volcanic production, consisting of basaltic amygdaloid. On the summit of one of the neighbouring mountains (the Treayle), is found a crater 300 feet in circumference and 100 feet in perpendicular depth. In the environs of Durango there is also to be found, insulated in the plain, an enormous mass of malleable iron and nickel, said to weigh upwards of 40,000 pounds avoirdupois, and corresponding in its composition to the aëroliths which fell in 1751, near Agram, in Hungary. Major Pike also informs us that there is "a mountain or hill of loadstone" about a hundred miles south of Chihuahua.

DURATION, an idea obtained by attending to the succession of feelings and thoughts in the mind. Duration, as marked by certain periods and measures, is what we most properly call *time*.

DURBUNGAH, a town of Hindustan, province of Bahar, district of Tirhoot, fifty-five miles north-north-east from Patna. The inhabitants are chiefly Mahommedans, who support themselves by breeding horses. Long. 85. 54. E. Lat. 25. 7. N.

DUREN, a circle in the Prussian government of Aix-la-Chapelle, extending over 122 square miles, and containing 38,048 inhabitants, in three cities, one market-town, and twenty-seven villages. The chief place, a city of the same name, is situated on the river Roer, and is a manufacturing place for fine cloths, blankets, paper, and ironmongery. It contains four churches, and 4938 inhabitants.

DURER, ALBERT, descended of an Hungarian family, and born at Nuremberg in May 1471, was one of the best engravers and painters of his age. He was a man of letters and a philosopher, and an intimate friend of Erasmus, who revised some of the pieces which he published. He was a man of business also, and for many years the leading magistrate of Nuremberg. Though not the inventor, he was one of the first improvers of the art of engraving; and he bethought himself of working also in wood, on which he engraved the life and passion of Christ in thirty-six pieces, which were very highly esteemed. In many of those prints which he executed on copper, the engraving is exceedingly elegant. His Hell scene particularly, which was engraved in the year 1513, is as highly finished a print as ever was engraved, and as happily executed. In his wooden prints too we are surprised to see so much meaning in so early a master; the heads being well marked, and every part admirably executed. This artist seems to have understood the principles of design. His composition, too, is often pleasing; and his drawing generally good. But he knew very little of the management of lights, and still less of grace; yet his ideas are purer and more elegant than we could have supposed from the awkward archetypes which his country and education afforded. In a word, he was certainly a man of very extensive genius; and, as Vasari remarks, he would have been an extraordinary artist if he had had an Italian instead of a German education. His prints are very numerous, and were much admired and eagerly bought up in his own lifetime. He was rich, and chose rather to practise his art as an amusement than as a business. This eminent person died at Nuremberg, on the 6th April 1528, and was interred in St John's Church, where an inscription was placed over his remains. Durer wrote several books in German, which were translated into Latin by other persons, and published after his death. Among these we may mention, 1. *De Symmetria Partium in rectis formis Humanorum Corporum*, Nuremberg, 1532, Paris, 1557, fol.; 2. *Institutiones Geometricæ*, Paris, 1532; 3. *De Urbibus, Arcibus, Castellisque condendis et muniendis*, Paris, 1531; 4. *De Varietate Figurarum, et flexuris Partium, et gestibus Imaginum*, Nuremberg, 1534. (See *Reliquien von Albrecht Dürer, seinen Verehrern geweiht, Taschenbuch* *für Deutschland's Kunstfreunde, zu Albrecht Dürer's dritter Secular-feier*, Nürnberg, 1828.)

DURESSE, Hardship, in *Law*, is where a person is kept in prison or restrained of his liberty contrary to order of law; or is threatened to be killed, maimed, or beaten. In which case, if a person so in prison, or in fear of such threats, make any specialty or obligation, by reason of such imprisonment or threats, such deed is void in law; and in an action brought on such specialty, the party may plead that it was brought by duresse.

D'URFEY, Thomas, more generally known by the familiar name of Tom d'Urfey, an English satirist and songster, of whom, though his name was as well known as that of any writer extant, yet few particulars have been collected. He was born in Devonshire; but when, where, or of what family, is uncertain. He was bred to the law, which he forsook for the more agreeable employment of writing plays and songs; and the latter he had so happy a talent both of writing and singing, that he received many favours from persons of quality on that account. Even crowned heads did not disdain his company. A writer of the Guardian (No. 67), tells us, he remembered to have seen Charles II. leaning on Tom d'Urfey's shoulder more than once, and humming over a song with him. This indeed was not extraordinary in so merry a monarch; but even the phlegmatic King William could relax the rigour of his Dutch muscles on hearing Tom sing a song. He was certainly by all accounts a cheerful, honest, good-natured man; but as this character does not include prudence, D'Urfey became poor as he grew old; and having prevailed on the managers of the playhouse to act his comedy of the *Plotting Sisters* for his benefit, Mr Addison wrote the above-mentioned paper in the Guardian, with another (No. 82) representing him in a good-humoured light, in order to procure him a full house. He died at an advanced age, in 1723.

DURHAM, Bishopric of, one of the counties of England. Before the arrival of the Romans it was included in the British principality of the Brigantes, and after their arrival made part of the province of *Maxima Cæsariensis*. During the heptarchy it formed part of the kingdom of Northumberland, the fifth established, which began in 547, and ended in 827, having been governed by thirty-one kings. It was not mentioned by Alfred in his division of counties, being at that time considered as a part of Yorkshire. At present it is included in the northern circuit, in the province of York, and is a diocese and principality under the government of its own bishop, being a county palatine, the second in rank, and the richest in England. It is bounded on the north by Northumberland, on the south by Yorkshire, on the east by the North Sea, and on the west by Cumberland. It extends, according to the view of Mr Rickman, over 1061 square miles, and contains one city of the same name, nine market-towns, and 223 villages. It is divided into four wards. Until the passing of the reform act, it returned two members to the House of Commons for the county, and two for the city. The county has been formed, by that law, into two divisions, for the purpose of parliamentary elections; each of which returns two members. The northern division comprehends the wards of Chester and Easington, and the polling places are Durham, Sunderland, Lancheton, Wickham, Chester-le-Street, and South Shields. The southern division comprehends the wards of Darlington and Stockton, and the poling places are these two towns, and Bishop Auckland, Stanhope, Middleton-in-Teesdale, Barnard Castle, and Sedgefield. The following places within the county have by the same law obtained the privilege of electing two members each, viz. Gateshead, South Shields, Sunderland, and Tynemouth.

This is the only county palatine remaining in England, and it is called *palatine*, *a palatio*, because the owners thereof had, in this county, the authority to use the royal prerogative, as fully as the king had in his palace. The palatine privileges were granted to this county probably on account of its bordering upon the inimical kingdom of Scotland, in order that the inhabitants, having justice administered at home, might not be obliged to go out of their county, and leave it open to an enemy's incursions; and that the owners, being encouraged by so large an authority, might be the more watchful in its defence. There is a court of chancery in this county, and the bishop is at the head of the administration of justice.

The western angle of the county of Durham is hilly and mountainous, with black, naked, and barren regions, crossed by a ridge of high hills, from whose sides issue numerous streams flowing to the sea. There are some beautiful and fertile valleys in the eastern and central parts, pleasantly varied with hill and dale, and alternately appropriated to corn and pasture. The waste lands occupy nearly 120,000 acres of the western part of the county; but in the southern districts many hundred acres have been inclosed and cultivated within the last forty years. The common fields are now but few; for the land belonging to the townships has been inclosed for above a century. There is a great portion of wet ground still remaining, although draining is carried on to a great extent.

Near the river Tees, and in some spots bordering on the other rivers, the soil is loam or a rich clay. At a farther distance from these rivers the soil is of an inferior quality, and marshy, with patches of gravel interspersed. The hills between the sea and an imaginary line from Barnard Castle on the Tees to Alansford on the Derwent, are covered with a dry loam, the fertility of which varies with its depth. From this line westward the summits as well as the sides of the hills are moorish wastes.

The woodlands of Durham are not of very considerable extent, trees being chiefly confined to the parks and seats of the nobility and gentry, but many plantations have been made of late years. The banks of the rivers and brooks, however, particularly in the vicinity of Durham, are fringed with wood of long growth and much value. The public roads are in general good, but those belonging to private districts and townships want improving.

The port of Stockton-upon-Tees is well situated for commerce. Hartlepool, situated on a promontory, nearly encompassed by the German Ocean, which on the south side of the town forms a capacious bay, is advantageously placed for the reception of vessels, and landing of troops from the Continent; and South Shields sends out many ships.

The mineralogical substances found in Durham are numerous and valuable. The coal mines are some of the most extensive and productive in the kingdom, and the quantity of this important article is so great as to exceed all calculation. At Sunderland the coal trade furnishes employment for 520 vessels, independently of the *keels* which convey the coal from the staiths to the ships, which are 492 in number. This coal is chiefly conveyed to the metropolis, though great quantities are sent to the different ports of the Baltic, and in time of peace to France and Holland. The whole quantity annually exported from Sunderland alone amounts to about 315,000 Newcastle chaldrons, each chaldron being equal to 53 cwt. The number of persons dependent on this trade is very great, and some years ago, when the consumption was by no means so great as it is at present, amounted to upwards of 26,000 on the river Wear only. The seams or strata now worked are five in number, extending horizontally for many miles, and are from twenty to one hundred fathoms beneath the surface; while each stratum is from three to eight feet thick. Below these are several other seams of coal; and many parts of the county, besides those where the pits are now open, abound with this substance.

The principal lead mines of Durham are situated in Teesdale and Weardale; those of the former place have not been very productive, but the produce of the latter is of considerable value. The general method of working them is similar to that pursued in other mining counties. The ore of Weardale is melted by the blast-hearth, but in Teesdale air-furnaces have been introduced with much success.

Ironstone is found in the neighbourhood of Swalwell and Winlaton, where are the first iron-works in England.

Some excellent quarries of slate for buildings have been opened in different parts of the county. A beautiful black spotted limestone is dug up near Walsingham, and made into hearths, chimney-pieces, and other ornaments. This neighbourhood abounds also with fine millstones. The Newcastle grindstones are procured at Gateshead Fell; and firestone of high estimation, for building ovens, furnaces, and the like, is obtained in various parts of Durham, and exported in immense quantities.

Several extensive works for manufacturing salt from sea-water have long been established in the neighbourhood of South Shields; but owing to the discovery of a very singular salt spring at Birtley in this county, that process is not so much attended to now. This water rises at the depth of seventy fathoms, in an engine pit constructed for drawing water out of coal mines. It has for many years produced 20,000 gallons per day, four times more strongly impregnated with salt than any sea-water. In consequence of the discovery of this spring, about twenty-five years ago, a large and extensive manufactory of salt has been established near the spot, the quality of which is excellent. At Butterby, near Durham, is another salt spring, which issues from a rock in the river Wear, but is only visible when the water is low; it contains more of the sulphate of magnesia, or Epsom salt, than the spring at Birtley. Within a few yards of the Water-gate, on the south side of the town of Hartlepool, is a chalybeate spring, covered every tide by the sea. It is impregnated slightly with sulphur, which evaporates very quickly, leaving a sediment with salt of tartar; a gallon will yield 120 grains of sediment, two parts of which are nitrous, and the rest limestone.

Improvements in agriculture have been pursued with considerable spirit and success, in the environs of Darlington, chiefly through the patronage of a society of respectable gentlemen, who hold their meetings in the town, and bestow premiums upon merit. The usual rotation of crops in this county is, after summer fallow, wheat, oats, beans, or peas. On some spots of gravelly soil, turnips and barley are grown in almost perpetual succession, a crop of clover being sometimes interposed. The produce of wheat on good land is from twenty to thirty bushels per acre, the produce of barley is from thirty to forty, of oats from twenty to forty. The manures are chiefly lime and the produce of the fold-yard; and though abundance of sea-weed might be collected on the coast, the farmers make but little use of it. The farms are of a middling size, few of them exceeding 200 acres. The largest portion of each farm is appropriated to tillage, but towards the western extremity of the county the whole is applied to pasture. The leases seldom exceed six years, and are too frequently rendered of little value by injudicious restrictions. The leases held of the see of Durham are generally for life, or for twenty-one years, renewable every seven years on payment of a fine. The farm-houses are well situated and commodious, and improvements in farming and farming machinery become more and more common.

The cattle at Durham are, at present, in great repute; as, for form, weight, produce of milk, and quickness of fattening, there are none better. The sheep also, particularly the Tees Water breed, stand high in estimation. It is the largest breed in the island; the legs being longer, finer boned, and supporting a thicker and more firm and heavy carcass, than the Lincolnshire. They are also much wider on the backs and sides, and afford a fatter and finer grained mutton. The weight per quarter, in two-years' old wethers, is from twenty-five to thirty-five pounds, and in particular instances fifty-five pounds or more. The wool is shorter and lighter than some other English breeds. The Weardale sheep are small, but the meat is finely flavoured. When fat, the quarters seldom weigh more than fourteen or eighteen pounds each.

Durham, taking its dimensions into consideration, is inferior to no county in Great Britain for its numerous manufactures. It has cast-metal founderies, iron manufactories, potteries, glass-houses, copperas works, coal-tar and salt-works, quarries of marble, &c.; besides linen and woollen manufactories.

At the distance of about three miles from Darlington, at Oxenhall, are cavities in the earth, denominated Hell Kettles, to the origin of which are attached many fabulous conjectures. The diameter of the largest is not less than 114 feet, and that of the least seventy-five. About five miles from Hartlepool is one of the most singular and romantic clusters of rocks in the north of England, called Black Halls, formed by the force and constant action of the waves, which have separated enormous masses from the coast, washing some entirely away, but leaving others standing, like the vast towers of a cathedral; in some places the rock is perforated so as to resemble a fine pointed archway.

Near the north wall of the church-yard at Ryton is a large barrow, about twenty feet in perpendicular height, now planted with trees. It does not appear to have been opened; but a similar one, near Bradley Hall, in the same parish, inspected about thirty-five years ago, was found to contain a square cavity, formed by stones placed edgewise, in which a human body had been interred. Between one and two miles north of Brancepeth is Brandon Hill, a lofty eminence, on the summit of which is a remarkable tumulus, of an oblong form, 120 paces in circumference at the base, and about twenty-four feet in perpendicular height. It does not appear to have been opened. One mile north of Eggleston is an ancient structure, called the Standing Stones. This originally consisted of a cairn in the centre, surrounded by a trench, and that again encompassed by a circular arrangement of rough stones, many of which have been removed and broken, to repair the roads. Near a brook, at a small distance, is a large barrow, crossed from east to west by a row of stones.

On Fullwell Hill, a gigantic skeleton and two Roman coins were discovered about fifty-five years ago, together with a small urn of unbaked clay. Several copper coins have been found at the village of Whitburn. Some coins of the Emperor Hadrian were found while widening the road near Gateshead, which is supposed to have been a Roman station.

South Shields was the *ad finem* of Richard of Cirencester's itinerary, as appears from the Roman altars, coins, and other relics found there. Evchester, a small irregular village, is supposed to be the *Vindomara* of Antoninus; many Roman inscriptions, and an urn of uncommon form, nearly a yard high and seven inches wide, with a small cup in the centre, having been found there. Chester-le-Street has been supposed to be the *Condercum* of the

Romans, situated on the military way leading to Newcastle. Glanibanta, near the village of Lanchester, is another Roman station, which has survived the ravages of cultivation in an extraordinary degree, and is one of the most perfect in the kingdom. It occupies a fine eminence, and is of an oblong figure, being 174 paces from north to south, and 160 from east to west, within the vallum. In some parts the wall still remains perfect; the outside is perpendicular, twelve feet in height, and built of ashler work in regular courses, each stone being about nine inches thick and twelve long. The site of the Prætorium is clearly distinguishable. Binchester, the seat and manor of the Wren family, is the site of the Roman station called *Vinovium* by Antoninus. Its figure and extent seem nearly similar to those of the station just mentioned; but the walls have been destroyed, and the area inclosed and cultivated. A military way, it is supposed, issued from it, leading towards Chester-le-Street. Innumerable fragments have been discovered here.

The most ancient part of Durham Castle is the keep, now a mere shell; the magnificent hall is fast going to decay. Hilton Castle, an ancient baronial residence of the Hyltons, is situated in a pleasant vale on the north side of the Wear, about three miles from Wearmouth: its present form is that of an oblong square; the interior consists of five stories; the rooms are small, and exhibit every symptom of neglect and decay. Ravensworth Castle, the seat of Sir Thomas Henry, occupies part of the site of an ancient castle, which seems to have formed a quadrangle, having a square tower at each angle, connected by a curtain wall. Two of the towers are built up in the offices, the others are partly in ruins. Lumley Castle, about a mile to the east of Chester-le-Street, is one of the seats of the Earl of Scarborough. It forms a quadrangle, with an area in the centre; at each angle are projecting turrets of an octangular form; it is a grand model of the taste of its age. Brancepeth Castle, an irregular but stately pile, was erected about Stephen's reign, by the family of Bulmers. The original building has had many modern improvements added to it by the present proprietor. The castle of Bishop Auckland stands on the north angle of the town, and, together with its courts and offices, covers about five acres of ground. Raby Castle, the magnificent seat of the Earl of Darlington, owes its splendour to the Earl of Westmoreland, who enlarged a more ancient castle which stood here prior to the year 1379. The present mansion of Streatham Castle was erected on the foundation of the old castle at the beginning of the last century, and several of the apartments are retained in it. Barnard Castle is situated on the southern acclivity of an eminence, rising with a steep ascent from the river Tees; its ruins cover an extensive plot of ground.

Kepier Hospital, near Durham, was founded in 1112; but the only part of the monastic buildings now standing is the gateway, a strong and not unhandsome piece of masonry with pointed arches. The ruins of a monastery for gray friars may be seen at Hartlepool. Several remains of monastic buildings occur near the church at Monk Wearmouth. The monastery of Jarrow may still be traced in its ruins on the summit of an elevated ridge near the church. On the east side of the main street of Gateshead are the ruins of St Edmond's Monastery, which appears, from Bede, to have been established before the year 653. Finchall Priory was beautifully situated in a vale on the banks of the Wear; the ruins cover an extensive plot of ground, but are so much dilapidated that the original appropriation of their respective parts can be traced only with great difficulty. The remains of a chapel at Bear Park are most perfect, and display some neat ornamental architecture. There is at Walsingham the ruins of a considerable building, inclosed with a deep moat, supposed by some to have been a part of a monastery.

The ecclesiastical buildings now remaining, and most worthy of notice, are, the Cathedral of Durham, begun in 1093, in the Saxon and Norman style; Sedgefield Church, in the Saxon style; Bishop Wearmouth Church, supposed to have been founded very soon after the restitution made by Athelstan; and the parish church of Brancepeth, an ancient structure of the conventual form, but apparently of different ages.

The county of Durham contains a great number of noblemen and gentlemen's seats. The following are some of the principal: Streatham Castle, the seat of the Earl of Strathmore; Shincliff-Hall, that of R. Scott, Esq.; Croxdale-Hall, that of W. Salvin, Esq.; Raby Castle, that of the Duke of Cleveland; Lumley Castle, that of the Earl of Scarborough; Castle Eden, that of R. Burdon, Esq.; Harwicke, that of M. Russell, Esq.; Windleston, that of Sir John Eden, Bart.; Grange-Hall, that of G. Allan, Esq.; Winyard, that of the Marquis of Londonderry; Seaham, that of Sir R. Milbanke, Bart.; Ravensworth Castle, that of Sir S. H. Liddel, Bart.; Axwell Park, that of Sir T. Clavering, Bart.; Gibside, that of the Earl of Strathmore; Lambton Hall, that of Lord Durham; and Bradley Hall, that of the Bowes family.

The following titles are furnished from this county: Earl of Darlington to the Duke of Cleveland; Earl of Stanhope; Viscount Lumley to the Earl of Scarborough; Baron Auckland to the Eden family; and Baron Durham to the family of Lambton.

The inhabitants of this county, by accounts of doubtful accuracy, amounted in the year 1700 to 95,500, and in 1750 to 135,000. By the four decennial returns they are stated as follows: In 1801 they amounted to 160,561, in 1811 to 177,625, in 1821 to 207,673, and in 1831 to 253,700. The annual value of the real property appears by the assessment of 1815 to have been L.791,359.

DURHAM, a city, the capital of the county of that name, 260 miles from London. It is situated on the river Wear, which nearly surrounds it, and contributes to the fine situation; the castle and cathedral standing on an eminence, communicate no inconsiderable share of beauty. Besides the cathedral, there are six parish churches. The see is the most richly endowed of any in England, and the prebendaries are of great value. In the vicinity of the city are many interesting remains of antiquity. The corporation consists of a mayor, twelve aldermen, and twenty-four common council men, who nominate the freemen, by whom two members are returned to parliament. The market, held on Saturdays, is well attended. There is very little of trade, and there are no manufactures. The inhabitants amounted in 1801 to 7530, in 1811 to 6763, in 1821 to 9822, and in 1831 to 10,125.

DURKHEIM, a city, the chief place of a canton in the circle of the Rhine, in the kingdom of Bavaria. It stands on the river Isenach, and contains 500 houses, with 3081 inhabitants, who grow much wine.

DURLACH, a circle in the grand duchy of Baden, containing one city, two market-towns, and twelve villages, with 12,626 inhabitants. The capital is of the same name, situated on the river Pfing. It contains 471 houses, and 3873 inhabitants employed in making linen cloth, China ware, and other goods, and in growing fruit and wine.

DUROCHSKOI, a town of Asiatic Russia, in the government of Irkutsk, on the confines of China, near the Argun, 160 miles south-south-east of Nertchinsk.

DURON, an island in the Straits of Malacca, about twelve miles in length and three in breadth. Long. 103. 30. E. Lat. 0. 42. N.

DUROTRIGES, an ancient British nation, established in that part of the country which is now called Dorsetshire. Their name is derived from the two British words *dur*, water, and *trigo*, to dwell; and it seems pretty evident that they obtained their name from the situation of their country, which lies along the sea coast. It is not very certain whether the Durotriges formed an independent state under a prince of their own, or were united with their neighbours the Danmonii; for they were reduced by Vespasian under the dominion of the Romans, at the same time and with the same ease as the latter, and never afterwards revolted. The peaceable disposition of the inhabitants was probably the reason why the Romans had so few towns, forts, and garrisons in this pleasant country. Dorchester, its present capital, seems to have been a Roman city of some consideration, though our antiquaries are not agreed about its Roman name. It is most probable that it was the Durnovaria in the twelfth Iter of Antoninus. Many Roman coins have been found at Dorchester. The military way, called Jeening Street, passed through it; and some vestiges of the ancient stone-wall with which it was encompassed, and of the amphitheatre with which it was adorned, are still visible. The country of the Durotriges was included in the Roman province called *Flavia Cæsariensis*, and was governed by the president of that province as long as the Romans maintained any footing in these parts.

DUROUR'S ISLAND, in the East Indian Ocean, discovered by Captain Carteret in 1767. Long. 143. 21. E. Lat. 1. 15. S.

DURRAJAH, a town of Hindustan, belonging to the Mahrattas, in the province of Malwah, twenty-five miles north-west from Bopal. Long. 77. 9. E. Lat. 23. 28. N.

DURRAMPOOR, a town of Hindustan, in the province of Aurungabad, fifty miles south-south-east from Surat. Long. 73. 23. E. Lat. 20. 34. N.

DURRESTEIN, a town of Austria, in the province of the Lower Ens, and circle of Upper Manhartsberg. It is situated on the banks of the Danube, and belongs to Count Staremburg. Above it are the ruins of a castle in which Richard king of England was kept a prisoner. Near to it are extensive quarries of millstones and grindstones. The inhabitants are about 1000.

DURSLEY, a market-town of the hundred of Berkeley, in the county of Gloucester, 108 miles from London. It is a corporate town, but has long ceased to elect members of parliament. A considerable quantity of broad cloth is made, chiefly for the China trade. A market, held on Thursday, is well supplied. The inhabitants amounted in 1801 to 2379, in 1811 to 2580, in 1821 to 3186, and in 1831 to 3226.

DURY, JOHN, a Scotch divine, who travelled much, and laboured with great zeal to reunite the Lutherans with the Calvinists. His discouragements in this scheme started another still more impracticable, namely, to reunite all Christians by means of a new explication of the Apocalypse, which he published at Frankfort in 1677. He there enjoyed a comfortable retreat in the country of Hesse; but the time of his death is unknown. His letter to Peter du Moulin, concerning the state of the churches of England, Scotland, and Ireland, was printed at London in 1658, under the superintendence of Du Moulin, and is esteemed curious.

DUSKY BAY, on the west coast of Tarai Poenammoo, one of the islands of New Zealand. It is of considerable extent, and affords good anchorage in coves and harbours near the shore. In other parts of it the water is very deep. This bay was discovered by Captain Cook in 1769. Long. 166. 48. E. Lat. 45. 40. S.

DUSSARA, a fortified town of Hindustan, province of Gujerat, which contains about 1300 houses, which are chiefly possessed by Kurbatties; the remainder of the population being Coolees, Rajpoots, and other castes, besides a few Banyans. This place, with twelve surrounding villages, is the property of a Mahommedan zemindar, of Arabian descent, one of whose ancestors, about the year 1209, was put to death for killing a cow, and he has since been considered as a martyr, and his tomb is held in high esteem. The military force of the chief is estimated at 2000 horsemen and 100 infantry.

DUSSAULX, JOHN, a French writer, best known as the translator of *Juvenal*, was born at Chartres, on the 28th of December 1728. He studied first at La Fleche, and afterwards at Paris; and having obtained the situation of a commissary in the *gendarmerie*, he served under the Marshal de Richelieu, in Hanover, during the seven years' war. At the age of twenty-one he was admitted a member of the academy at Nanci; and in 1770 he published his translation of *Juvenal*. This work procured him admission into the Academy of Inscriptions; and he was also appointed ordinary secretary to the Duke of Orleans.

For some years he quietly prosecuted his literary occupations at Paris; but, upon the breaking out of the Revolution, his enthusiastic disposition led him to adopt its principles; and he took part in the debates of the legislative assembly. He spoke and voted, however, at all times for moderate measures; and, on several occasions, he was employed to calm the passions of the people during public tumults. At the memorable sitting of the convention of the 15th of January 1793, he voted that the king should be detained in custody during the war, and banished on the return of peace. It is rather remarkable, that when the committee of public safety wished to send him to the scaffold, his pardon was obtained by Marat, who represented him as an old dotard, incapable of becoming dangerous. He became president of the council of ancients in the month of July 1796, but left it in 1798. At the sitting of the 27th of April, he took leave of the assembly in a speech which was ordered to be printed. He died on the 16th of March 1799, after a long and painful illness.

Dussaulx was a man of considerable literary attainments, and amiable, upright, and disinterested in his conduct. His translation of *Juvenal* is esteemed the best version of that poet in the French language. His other works are, *Mémoires sur les Satiriques Latins; Lettres et Réflexions sur la fureur du Jeu, auxquelles on a joint une autre Lettre Morale*, Paris, 1775; *Discours sur la Passion du Jeu dans les différents Siècles; De la Passion du Jeu, depuis les temps anciens jusqu'à nos jours*, 1779, 8vo; *Vie de l'Abbé Blanchet*, prefixed to the *Apologues and Tales* of that author, Paris, 1784, 8vo; *De l'Insurrection Parisienne, et de la prise de la Bastille*, Paris, 1790; *Lettre au Citoyen Fréron*, 1796, 8vo; *Voyage à Barrège, et dans les Hautes-Pyrenées*, Paris, 1796, 2 vols. 8vo; *De mes Rapports avec Jean-Jacques Rousseau*, &c. Paris, 1798, 8vo, a curious work, which throws considerable light on the character of that celebrated man.

Marie-Jeanne Lieutau, the widow of Dussaulx, published memoirs of his life, which are exceedingly interesting. See also Palissot, *Mémoires sur la Litterature*; and *Biographie Universelle*.

DUSSELDORF, a circle of the Prussian province of Westphalia, on the right bank of the Rhine. Its extent is 144 square miles, and it comprehends three cities, two market-towns, and thirty-four villages, with a population of 28,500 inhabitants.

DUSSELDORF, a city, the capital of the circle of the same name, in the Prussian dominions. It stands where the river Dussel falls into the Rhine. It is one of the finest cities of Germany; and, though deprived of the splendour it exhibited under its ancient dukes, has become a flourishing place by the introduction of various manufactures. The former fortifications are converted into extensive and prolific gardens. It contains three Catholic, one Lutheran, one reformed church, and ten chapels, with a house of industry, penitentiary, and an hospital, with appropriate institutions for education. The houses are 1387, and the inhabitants, including the military, in 1817 were 18,084. Long. 6. 40. 35. E. Lat. 51. 14. 12. N.

DUST, or Dustee, a river of Persia, flowing from the interior through the province of Mekran, from the southern shore of which it is discharged into the Indian Ocean. Its course is supposed to extend, under different appellations, about 1000 miles.

DUTENS, Louis, a late French writer of some celebrity, was born at Tours, of Protestant parents, on the 15th of January 1730. In his youth he addicted himself to poetry; and in 1748 he repaired to Paris and composed a tragedy, entitled *The Return of Ulysses to Ithaca*, which he showed to the comedian Lanoue, requesting him to bring it on the stage. The latter, however, returned the piece, advising the author to retouch it. Irritated at this advice, Dutens went to Orleans, where he got his play represented with great applause; but he soon became sensible of the faults of his work, and abandoned a species of composition in which he found he was not destined to excel. He soon afterwards went to England. Before leaving France, he accidentally became acquainted with Miss Pitt, sister to the Earl of Chatham, who gave him a letter to her brother; but after a short stay in London he returned to France. Not long afterwards, he was recalled to London by one of his uncles, to accompany a young English nobleman on his travels. Soon after his arrival, the young nobleman changed his intention; but, at the same time, he procured for Dutens the situation of a tutor in a private family. The father of the pupil was a man of considerable literary and scientific attainments, who instructed Dutens in those branches of knowledge in which he was deficient. In this manner he learnt Greek and mathematics; and he at the same time applied himself to the oriental languages, and to Italian and Spanish. At the end of three years his pupil died; but one of his sisters being deaf and dumb, Dutens undertook to educate her. His young pupil, however, having become enamoured of her instructor, he deemed it a matter of delicacy and of duty to leave the house.

About this time he was appointed chaplain and secretary to the Honourable Mr Stuart Mackenzie, the English minister at the court of Turin, and left England in the month of October 1758. In 1760, when Mr Mackenzie returned to England, the secretary remained at Turin as chargé d'affaires. Dutens came to England in 1762, and attached himself to the family of Lord Bute, who, before he retired from office in 1763, procured him a pension. He again went to Turin as chargé d'affaires, and during this second mission he undertook the task of collecting and publishing a complete edition of the works of Leibnitz, and wrote his work on the *Discoveries of the Ancients*. He afterwards quitted Turin, returned to Britain, and attached himself to the Duke of Northumberland, who procured him a living in the north of England. He accompanied the duke's son, Lord Algernon Percy, in his travels through France, Italy, Germany, and Holland; and while at Paris, he was chosen a member of the Academy of Inscriptions. In 1776 he returned to England, and soon afterwards accompanied Mr Mackenzie and his lady on a tour to Naples. On his return he was invited by Lord Mountstuart, who had been appointed envoy extraordinary, to accompany him to Turin, and Dutens found himself for the third time chargé d'affaires at that court, during a short absence of the envoy. From Turin, which he left on account of some unpleasant circumstances, he went to Florence, and thence to Rome. He was in Paris in 1783, and returned to London the following year. The revenue he derived from his living of Elsdon, amounting to L.800 per annum, together with a considerable legacy left him by Mr Mackenzie, and estimated at L.15,000, enabled him to pass the remainder of his life in affluence, and in the best company. He died at his house, Mount Street, Grosvenor Square, on the 23d of May 1812.

Dutens was the editor of the works of Leibnitz, published at Geneva, 1769, in 6 vols. 4to; of the Greek pastoral romance of *Daphnis and Chloe*, by Longus, 1776, 12mo, and of Dacier's translation of the *Manual of Epictetus*, 1775, 18mo. He was also the author of the following works: *Le Caprice Poétique*, a collection of poems, 1750, 16mo. *Recherches sur l'origine des Découvertes attribuées aux Modernes*, 1766, 2 vols. 8vo, 4th edition, 1812. *Poesies*, 1767, 12mo, and 1777, 8vo. *Le Tocsin*, Rome, 1769, 12mo, reprinted under the title of *Appel au bon Sens*, London, 1777, 8vo. This work was directed against the French philosophers, and was published anonymously. *Explication de quelques médailles de Peuples, de Villes, et de Rois, Grecques et Pheniciennes*, 1773, 4to. *Explication de quelques médailles du cabinct de Duane*, 1774, 4to. *Troisième Dissertation sur quelques médailles Grecques et Pheniciennes, où se trouvent des observations pour servir à l'étude de la Paléographie Numismatique*, 1776, 4to. Dutens, at the same time, published a more complete edition of the two preceding works. *Logique, ou l'art de Raisonner*, 1773, 12mo, 1777, 8vo, and reprinted also in his miscellaneous works. *Du miroir ardent d'Archimède*, 1755, 1777, 8vo; *Des pierres précieuses et des pierres fines, avec les moyens de les connaître et de les évaluer*, 1776, 12mo, and reprinted at London and Paris. *Itinéraire des routes les plus frequentées, ou Journal d'un Voyage aux principales Villes d'Europe*, 1775, 8vo, and frequently republished with additions and improvements. *Lettre à M. D. B. (Debure) sur la réfutation du livre l'Esprit*, par J. J. Rousseau, 1779, 12mo, which contains some letters of Helvetius and Rousseau. *De l'Eglise, du Pape, de quelques points de controverse, et moyens de réunion de toutes les Eglises Chrêtiennes*, 1781, 8vo; several times reprinted, and finally under the title of *Considérations Théologiques sur les moyens de réunir toutes les Eglises Chrêtiennes*, 1798, 8vo. *Œuvres melées*, 1784, 8vo. Under the same title almost the whole works of Dutens were collected and published at London, 1797, 4 vols. 4to. *L'Ami des étrangers qui voyagent en Angleterre*, 1789, 8vo, frequently reprinted. *Histoire de ce qui s'est passé pour le rétablissement d'une régence en Angleterre*, 1789, 8vo. *Recherches sur le tems le plus reculé de l'usage des Voutes chez les anciens*, 1795. *Mémoires d'un Voyageur qui se répose*, Paris, 1806, 3 vols. 8vo. The two first volumes contain the life of the author, written in a romantic style; the third bears the title of *Dutensiana*, and is filled with remarks, anecdotes, bon mots, and so forth. Dutens is the author of the *Catalogue of Medals* in Swinburne's *Travels*, and of the French text to the second volume of the *Marlborough Gems*. There is a *Memoir* of his in the Collection of the Academy of Inscriptions, and he also published a small tract on the *Iron Mask*. He was a member of the Royal Society of London, and had the title of historiographer to the king. (See Memoirs of Dutens in the *Gentleman's Magazine for* 1812; Chalmers's *Biographical Dictionary;* and *Biographie Universelle.*)

DUTCHY. See Duchy.

DUTY, in general, denotes any thing that one is obliged to perform.

Duty, in commerce, signifies an impost laid on merchandise, at importation or exportation, commonly called the duties of customs; also the taxes of excise, stamp duties, &c. See Political Economy, and Taxation.

DUUMVIRI, in Roman antiquity, a general appellation given to magistrates, commissioners, and officers, where two were joined together in the same functions.

Duumviri Capitales were the judges in criminal causes. From their sentence it was lawful to appeal to the people, who alone had the power of condemning a citizen to death. These judges were taken from the body of the decuriones, and had great power and authority; they were members of the public council, and had two lictors to walk before them.

Duumviri Municipales were two magistrates in some cities of the empire, answering to the consuls at Rome. They were chosen out of the body of the decuriones, and their office commonly lasted five years, upon which account they were frequently termed *quinquinales magistratus.* Their jurisdiction was of great extent. They had officers who walked before them, carrying a small switch in their hands; and some of them assumed the privilege of having lictors carrying axes and the fasces or bundles of rods before them.

Duumviri Navales were the commissaries of the fleet, first created at the request of M. Decius, tribune of the people, in the time of the war with the Samnites. The duties of their office consisted in giving orders for the fitting out of ships, and issuing their commissions to the marine officers, &c.

Duumviri Sacrorum were magistrates created by Tarquinius Superbus for the performance of the sacrifices, and for keeping the sibyls' books. They were chosen from among the patricians, and held their office during life; they were exempted from serving in the wars, and from the offices imposed on the other citizens; and without them the oracles of the sibyls could not be consulted.

DWAL, in *Heraldry*, the herb nightshade, used by such as blazon with flowers and herbs, instead of metals and colours, for sable or black.

DWARACA, a town and celebrated temple of Hindustan, province of Gujerat, situated at the south-west extremity of the peninsula. There are twenty-one villages belonging to Dwaraca, containing 2500 houses, and, on the most accurate calculation, 100,000 inhabitants. The inhabitants were formerly much addicted to piracy, but of late years have been restrained by a treaty with the British. The temple is fabled to have been the residence of Krishna, at which 15,000 pilgrims annually pay their devotions, which is an abundant source of wealth to the Brahmins. Long. 69. 15. E. Lat. 22. 21. N.

DWARF, in general, an appellation given to things greatly inferior in size to that which is usual in their several kinds. Thus there are dwarfs of the human species, dwarf dogs, dwarf trees, and the like.

The Romans were passionately fond of dwarfs, whom they called *nani* or *nanæ*, insomuch that they often used artificial methods to prevent the growth of boys designed for dwarfs, by inclosing them in boxes, or by the use of tight bandages. Augustus's niece, Julia, was extremely fond of a dwarf called Sonopas, who was only two feet and a handbreadth in height. We have many other accounts of human dwarfs, but most of them deformed in some way or other, besides the smallness of their size. Many relations concerning dwarfs we must necessarily look upon as not less fabulous than those concerning giants. The following history, however, which there is reason to regard as authentic, is too remarkable not to be acceptable to the generality of our readers.

Jeffery Hudson, the famous English dwarf, was born at Oakham, in Rutlandshire, in 1619; and about the age of seven or eight, being then but eighteen inches high, he was retained in the service of the Duke of Buckingham, who resided at Burleigh-on-the-Hill. Soon after the marriage of Charles I. the king and queen being entertained at Burleigh, little Jeffery was served up at table in a cold pie, and presented by the duchess to the queen, who kept him as her dwarf. From seven years of age till thirty he never grew taller; but after thirty he shot up to three feet nine inches, and there remained fixed. Jeffery became a considerable part of the entertainment of the court. Sir William Davenant wrote a poem called *Jeffreidos*, on a battle between him and a turkey-cock; and in 1638 was published a very small book, called the *New Year's Gift*, presented at court by the Lady Parvula to the Lord Minimus, commonly called *Little Jeffery*, her majesty's servant, written by Microphilus, with a little print of Jeffery prefixed. Before this period Jeffery was employed on a negotiation of great importance; he was sent to France to fetch a midwife for the queen; and on his return with this gentlewoman and her majesty's dancing-master, and many rich presents to the queen from her mother Mary de' Medicis, he was taken by the Dunkirkers. Jeffery, being thus made of consequence, began to think himself really an important personage. He had borne with little temper the teasing of the courtiers and domestics, and had many squabbles with the king's gigantic porter. At last, being provoked by Mr Crofts, a young gentleman of family, a challenge ensued; and Mr Crofts coming to the rendezvous armed only with a squirt, the little creature was so enraged that a real duel ensued; and the appointment being on horseback with pistols, to put them more on a level, Jeffery, with the first fire, shot his antagonist dead. This happened in France, whither he had attended his mistress in the troubles. He was again taken prisoner by a Turkish rover, and sold into Barbary. But he probably did not remain long in slavery; for at the beginning of the civil war he was made a captain in the royal army, and in 1644 attended the queen to France, where he remained till the Restoration. At last, upon suspicion of his being concerned in the Popish plot, he was seized in 1682, and confined in the Gatehouse, Westminster, where he ended his life, in the sixty-third year of his age. This little hero cuts a considerable figure in Sir Walter Scott's novel of *Peveril of the Peak.*

In the *Memoirs of the Royal Academy of Sciences*, a relation is given by the Count de Tressau, of a dwarf called *Bebe*, kept by Stanislaus, king of Poland, and who died in 1764, at the age of twenty-three, when he measured only thirty-two inches. At the time of his birth he measured only between eight and nine inches. Diminutive as were his dimensions, his reasoning faculties were not less scanty, appearing indeed not to have been superior to those of a well-taught pointer. But that the size and strength of the intellectual powers are not affected by the diminutiveness or tenuity of the corporeal organs, is evident from a still more striking instance of littleness, given us by the same nobleman, in the person of M. Borulawski, a Polish gentleman, whom he saw at Luneville, and who at the age of twenty-two measured only twenty-eight inches. This miniature of a man, considering him only with reference to his bodily dimensions, appeared a giant with regard to his mental powers and attainments. He is described by the count as possessing all the graces of wit, united with a sound judgment and an excellent memory; so that we may with justice say of M. Borulawski, in the words of Seneca, and nearly in the order in which he has used them, *posse ingenium fortissimum ac beatissimum sub quolibet corpusculo latere.*

DYEING

Is the art of communicating a new and permanent colour to any substance whatever; but it is usually confined to the art of giving colours to wool, silk, feathers, cotton, or flax, or the thread or cloth formed of any of these substances. To this more limited signification we shall restrict ourselves in the following treatise. For dyeing or staining *paper*, *wood*, *bone*, *leather*, *marble*, &c. the reader is referred to these articles. We shall divide this article into six chapters. In the first we shall give a rapid sketch of the history of the art; in the second we shall treat of the nature and properties of wool, feathers, silk, cotton, and flax, of which the fabrics to be dyed are composed; in the third chapter we shall treat of *mordants*, or the substances by means of which the colours are fixed on the cloth or thread. The fourth chapter will be occupied with the mode of dyeing the simple colours, or *red*, *yellow*, *blue*, *black*, and *brown*. The object of the fifth chapter will be the compound colours, or the different shades of *green*, *purple*, *orange*, and *gray*. The sixth chapter will be occupied with a sketch of the processes of calico printing. Our object will be to give a general view of the processes, and to explain the theory of dyeing, so far as the present state of our knowledge enables us to go. We shall avoid minute details, except when they may be necessary for understanding the nature of the processes.

CHAPTER I.

HISTORY OF DYEING.

Nature has implanted in man a sense of pleasure which he derives from beholding lively colours properly displayed and contrasted. And this sense receives ample gratification from the gay plumage of the feathered tribes, and the endless variety displayed in the blossoms of the vegetable kingdom. The diversity in the colours of flowers must have early attracted the attention of man, and he could scarcely avoid feeling a desire to employ them to adorn his person; but their fading nature fitted them only for a temporary ornament. It would naturally occur to attempt to transfer some of the most lively colours of the vegetable kingdom either to the skin of the naked savage, or to the different articles of dress with which he covered himself up from the cold, or with which he decorated his person.

A few trials would speedily show that the gay colours of most flowers could not be transferred to any article of dress, at least without a great diminution of their splendour; but a considerable difference would be observed depending upon the colour of the flower. The *red* flowers would either lose their colour altogether, as they would communicate to cloth, not a *red*, but a *blue* colour. The yellow coloured berries, on the other hand, would be found in some instances to communicate a very lively and beautiful, though not a permanent colour.

By multiplying trials, various roots, barks, and fruits would be found capable of communicating certain colours to cloth. These facts would be treasured up, and thus a beginning would be made of the art of *dyeing*. Accordingly we find this art practised to a greater or smaller extent in the most remote ages, and among the most savage and barbarous nations. Even the lowest of the American tribes, in point of civilization, understood how to communicate several very fine colours, and considerable improvements in dyeing were borrowed from the Americans.

Produced early in Egypt.

It would be in vain, therefore, to attempt to discover to whom the art of dyeing is indebted for its origin, as the practice of it precedes the origin of history. From the writings of Moses, who led the Israelites out of Egypt about 1555 years before the commencement of the Christian era, it is obvious that the art of dyeing had in his time made great progress in Egypt. He mentions blue, and purple, and scarlet, and badgers' skins dyed red.[1] There are some reasons for believing that what is translated in the Old Testament *fine linen* was in reality a cloth made of cotton wool. Indeed it is certain that cloth made of cotton was used in India and Egypt in the most remote ages. Cotton wool would naturally attract the attention of mankind in those countries where the plant which yields it grows. Now we know that the cotton plant is a native of India. India and Egypt are countries in which the processes of dyeing are as likely to have originated as any other; for they constitute the cradle of the human race, and civilization appears to have made earlier progress in them than in any other.

Tyrian dye.

The art of dyeing was brought to a considerable degree of perfection at a very early period in Phœnicia. It appears that it was in Tyre where the method of dyeing woollen cloth *purple* was first discovered; and this discovery, there is reason to believe, is at least as old as the time of Moses. The purple was communicated by means of several species of univalve shell-fish, which no doubt abounded on the coast of Phœnicia. Pliny, in the thirty-sixth chapter of his sixth book, gives us an account of two species of shell-fish from which the purple was obtained. The first species was called *buccinum*, doubtless from some resemblance to a hunting horn; the second was called *purpura*. A single drop of the dyeing liquor was obtained from each fish by opening a vessel situated in the throat of the animal. The liquor, when extracted, was mixed with a considerable portion of salt, to prevent putrefaction. It was then diluted with five or six times as much water, and kept moderately hot in leaden or tin vessels, for the space of ten days, during which the liquor was frequently skimmed, to separate all impurities. After this, the wool, being first washed, was immersed and kept in the liquor for five hours. It was then taken out, carded, and again immersed and kept in the liquor till all the colouring matter was extracted. To produce particular shades of colour, carbonate of soda, urine, and a marine plant called *fucus*, were occasionally added. Several of these colours are particularly described by Pliny, though it is difficult to form an accurate conception of his meaning. The *purple* itself seems to have been similar to the colour of blood.

Pliny says the Tyrians first dyed their wool in the liquor of the *purpura*, and afterwards in that of the *buccinum*. We find allusions to this practice in several passages of the Old Testament. Doubtless Horace alludes to the same process when he says,

> .... te bis Afro
> Murice tinctæ
> Vestiunt lanæ.
> *Od.* ii. 16, line 35.

---

[1] Exodus, xxv. 4 and 5.

History.

The shell-fish employed in this process were found abundantly both on the European and African shores of the Mediterranean. They still exist on these shores, and have been also met with abundantly on the coasts of England and France.

Purple.

The purple mentioned in Exodus was probably that dyed by the Tyrians. Ezekiel, who wrote about 593 years before the Christian era, in his prophecy against Tyre, says, "Fine linen with broidered work from Egypt, was that which thou spreadest forth to be thy sail; blue and purple from the isles of Elishah, was that which covered thee."[1] By Elishah it is generally supposed that Elis, on the west side of the Greek Peloponnesus, was meant. Hence it would appear that the Tyrians in Ezekiel's time drew their supply of shell-fish for dyeing purple from the coast of Greece.

From Herodotus it appears that purple was worn in Greece 559 years before the Christian era. It gradually made its way to Rome, and was purchased with avidity, notwithstanding its high price. After the establishment of the emperors upon the ruins of Roman liberty, the use of the purple was limited to the emperor, people of inferior rank being prohibited from wearing it, on pain of death. This of course sadly diminished the extent of the manufactory. It continued to languish for some centuries, and then became extinct; and the mode of dyeing the Tyrian purple was lost for many ages, but was again revived during the seventeenth century by Mr Cole of Bristol, and during the eighteenth century by M. Reaumur of France. But by this time finer colours had been discovered, and cheaper processes brought into use. It was not therefore thought advisable by the dyers to resume the methods followed by their Tyrian predecessors.

With the exception of the processes followed in the dyeing of purple, we are ignorant of the practices of the ancient dyers, or of the degree of progress which this *art* had made. Pliny, under whose province an account of dyeing naturally came, has passed it over in silence, and has assigned as a reason for his conduct that it was not reckoned among the liberal arts. *Nec tingendi rationem omisissemus, si unquam ea liberalium artium fuisset.*

Dyeing introduced into Greece.

The fine colours given in India to cotton cloths are universally known. The methods practised are no modern inventions, but were in common use when India was visited by Alexander the Great, and probably many ages before. These colours, which are both beautiful and permanent, prove that the methods of fixing gaudy colours on cotton were pretty far advanced. But these methods, as they have been described by Beaulieu and Bancroft, are so complicated, tedious, and imperfect, that they could be followed only where the wages of labour are exceedingly low, and never would answer in any part of Europe. There is reason to believe that the processes of dyeing cotton and linen were introduced into Greece only after the expedition of Alexander the Great into India.

The common people in Athens were very idle and very poor, spending their time in the public places, and receiving a daily pension of three oboli, or about fourpence halfpenny. But this sum would have purchased as much corn as three times the amount would do in this country; so that the income of a common Athenian citizen was equivalent to about thirteen pence halfpenny of our money. They went barefooted, and were dressed in garments which never had been dyed, but which were occasionally washed. The rich citizens wore garments which had been dyed; and the most common colour was *scarlet*, communicated to the cloth by *kermes*, a dyestuff still in use, and which we shall describe in a subsequent part of this treatise. This colour, as Pliny informs us, was scarcely less esteemed than the Tyrian purple. Cloths of the scarlet colour were worn by the emperors; and scarlet and purple seem to have been often confounded together.

The modes of dyeing black, blue, yellow, and green, were brought by Alexander the Great into Greece from India, as Pliny informs us.

Among the Romans, new-married women wore a *yellow* veil, and this colour was reserved for the women. In the circus the four different factions were distinguished by four different colours, one belonging to each faction. These were the green (*prasinus*), the orange (*rufatus*), the blue (*venetus*), and the white. These factions, with their colours, were transferred to Constantinople, and long distracted that city.[2] We are ignorant of the dyestuffs by means of which these colours were given to cloth.[3]

The want of soap, which was unknown to the Greeks, and only known to the Romans in Pliny's time as a pomatum for the hair, must have greatly cramped the processes of the ancient dyers; nor have we any evidence that *alum* was known to them, though they must have employed some substitute, otherwise the red colour of the kermes could not have been fixed upon the cloth. Alum appears to have been well known to Geber, who wrote in the eighth century. He mentions different manufactories of it, and talks of it as a substance familiarly known in his time. Is it not possible that the mode of making it had been known to the Tyrian dyers, but kept by them as a profound secret? The purple and scarlet dye was still in use during Geber's time, and even continued to be practised in the eleventh century. Alum, then, was certainly used by the Tyrian dyers before their manufactory was finally extinguished; but even if we admit that the ancients were unacquainted with *alum*, yet it is obvious, from Pliny's account of *alumen*, that it was a substance found native; that there were different species of it, for he enumerates four or five, and one of these may have been a native combination of sulphuric acid and alumina, which (if pure) would doubtless answer all the purposes of a mordant.

The ancient dyeing processes, such as they were, continued to be practised in Constantinople as long as the Greek empire lasted. It was during the crusades that the republics of Venice and Genoa reached the highest summit of their power. They were trading and manufacturing communities, and made a point of making themselves acquainted with the different arts at that time practised in Greece. Dyeing was not neglected by them; but the art and trade of the dyers of Constantinople were transferred by them to Italy.

Disco of arc

About the year 1300 a merchant of Florence accidentally discovered the method of making *archil*. He observed that a certain species of lichen (*lichen roccellus*), when macerated in urine, acquired a fine purple colour. This led him to try various experiments, which terminated in the discovery of archil, and in the application of it to the art of dyeing.

First tise on ing.

In the year 1429 the first collection of processes employed in dyeing was published in Venice, under the title *Mariegola dell' arte dei Tentori.* A second edition of this book, with many additions, was published in 1510. Giovan Ventura Rosetti formed the project of making this work more complete and more useful. He travelled into those parts of Italy and the neighbouring countries where attention was paid to the processes of dyeing, in order to acquire the requisite information. The result of his acquisitions was published under the name of *Plictho dell arte de' tentori, che insegna tenger panni, tele banbasi e sede, si per l'arte magiore, come per la commune.* It was published at Venice in the year 1548. A French translation of it appeared in Paris in the year 1716. This book constituted the first attempt at a methodical arrangement of the different processes. It even aimed at something like theory, though the state of knowledge at the time when it was written did not permit any successful explanation of the theory of dyeing.

---

[1] Ezekiel, chap. xxvii. ver. 7.

[2] See Gibbon's Decline and Fall, vii. 78.

[3] Berthollet has given a catalogue of the dyestuffs of the ancients, after Bischoff, *Elements de l'Art de la Teincture*, i. 14. We do not consider it as worth transcribing, because it is altogether conjectural.

Int duc- tion f indi and coch eal.

In the Plictho no notice is taken either of cochineal or indigo. Hence we may conclude that, in 1548, neither of these important dyestuffs had made their way into Europe. Pliny mentions indigo under the name of *indicum;* but it appears to have been used by the Greeks and Romans only as a paint; yet there can be little doubt that in India it had been employed from time immemorial as a dyestuff. Cochineal could not be known till after the discovery of America. It was used by the Mexicans as a dyestuff. In 1523 Cortes received orders from the court of Spain to multiply this precious insect, to collect it, and send it to Spain.

Cochineal by itself gives only a *crimson* colour; it dyes *scarlet* when mixed with a solution of tin. This fact was discovered accidentally by Cornelius Drebbel about the year 1630. He communicated his observation to his son-in-law Kuffelar, who was a dyer at Leyden. He soon brought the process to perfection, kept it a secret, and brought the scarlet colour into fashion. Soon after, the same process was discovered by a German chemist called Keffler, who carried his secret to London in 1643. A Flemish dyer called John Kloeck got information of the process in 1647, and it gradually made its way through every country of Europe.

Indigo, though a much more important dyestuff than cochineal, did not make its way into general use without the greatest difficulty. The use of it was prohibited in England during the reign of Elizabeth; and the prohibition was not taken off till the time of Charles II. It was equally prohibited in Saxony, where it was styled in the prohibition a corrosive substance, and called food for the devil. Restrictions on the use of indigo in dyeing were imposed also in France, though it was not altogether prohibited, as it had been in England and Saxony.

The reason of these prohibitions and restrictions was, that *pastel* and *woad* were employed for dyeing blue; and fears were entertained that indigo would supersede these dyestuffs altogether. Now, as they were the product of the different kingdoms of Europe when they were employed, it was erroneously concluded that the introduction of a better and cheaper dye would injure the country by throwing these plants out of cultivation.

Im ve- men in Fra e.

The improvements in dyeing which took place in France may be dated from the administration of Colbert, who paid particular attention to the different branches of manufacture which were carried on by the French. In the year 1672 he caused a book of instructions for dyers to be published in Paris. This book was republished in 1708 under the following title: *Le teincturier parfait, ou instruction nouvelle et générale pour la teincture des laines et manufactures de laine de toutes couleurs, et pour la culture des drogues ou ingredients qu'on y emploie.*

But Colbert's encouragement of dyeing was clogged with restrictions and prohibitions, which would have been fatal to the art, had it not been for the facility with which they were evaded. The revocation of the edict of Nantes in the year 1685 was a fatal blow to the pre-eminence of France in manufactures. The most industrious and skilful workmen and artists were driven out of the country, and carried their knowledge and dexterity into Great Britain, Holland, and Prussia. Succeeding administrations endeavoured as far as possible to correct the fatal policy of Louis XIV. The art of dyeing in particular drew their attention, and the most eminent chemists which the country possessed were placed as a kind of superintendents of the art of dyeing. Their business was to endeavour to improve the processes, and to bring the art to a state of perfection. Dufay, Hellot, Macquer, and Berthollet, successively filled this important office; and each of these eminent men contributed somewhat to the improvement of the theory of dyeing. Dufay first formed tolerably accurate notions of the nature of colouring matters, and of the forces which made them attach themselves to cloth. Hellot published a well-arranged treatise on dyeing woollen cloth, such as it was practised in the best dyeing establishments in France; and Macquer gave an equally detailed account of the processes followed by the silk dyers. Macquer indeed meditated a general treatise on dyeing, and published a prospectus in the year 1791. But his great age, and the feeble state of his health for some years before his death, prevented him from completing the undertaking.

Berthollet, who was named his successor as superintendent of dyeing, published an excellent treatise under the title of *Elements de l'Art de la Teincture*, a second edition of which appeared in the year 1804. This work contains a very full and complete account of the processes of dyeing, such as they existed when Berthollet wrote; and is still well entitled to the attention of the practical dyer.

Scarcely any work upon dyeing deserving the name of a scientific treatise appeared in the English language till Bancroft published his *Experimental Researches concerning the Philosophy of Permanent Colours, and the best means of producing them by dyeing, calico printing,* &c. in the year 1794. Of this work a second volume afterwards appeared, not inferior in value to the first. But unfortunately the projected plan was never completed. Had this been the case, the work of Bancroft would have been by far the completest treatise on dyeing in any language.

Great improvements have been made of late years in calico printing, and several new dyeing materials have been introduced. Of these the most important is the bichromate of potash and the sulphate of manganese. The former communicates an indelible yellow, orange, and red; the latter various shades of brown equally indelible, and at present constituting a very fashionable mode of printing. The improvements in the dyeing of silk and woollen cloth are not so easily pointed out, though they are both numerous and important. One, however, may be mentioned; the substitution of the lac dye in most ordinary cases for cochineal. This last dyestuff is still used for giving a scarlet colour to superfine cloth; but for the coarser fabrics lac is almost universally substituted. The calico printers employ only cochineal, and, so far as we know, never use lac.

CHAPTER II.

OF THE NATURE AND PROPERTIES OF THE SUBSTANCES TO WHICH COLOURS ARE COMMUNICATED IN THE PROCESSES OF DYEING.

There has been much speculation among philosophical dyers respecting the nature of the colouring matters, and the way in which the different colours are induced by dye-

Substances to be coloured.

ing; but these speculations have not led to any information of much value. It has been demonstrated by Newton that *light* is divisible into seven rays, distinguished by the following colours; *red, orange, yellow, green, blue, indigo, violet.* The colour of an object is owing to its having the property of reflecting or transmitting certain rays, while it absorbs the rest. Thus a red body reflects or transmits the red ray and absorbs the rest, an orange body reflects or transmits red and yellow, a green body reflects or transmits the yellow and blue rays, and a white body all the rays. There is reason for believing that the colouring matters employed as dyestuffs are all transparent, and that the colour is produced by their action on the light transmitted through them from the white fibres of the cloth. Those colouring matters that transmit all the rays equally leave the cloth white; if the blue ray be transmitted and the rest absorbed, the colour of the cloth will be *blue*, and so on. This is all that we know about the mechanical nature of the dyestuffs. On what the circumstance depends that causes a transparent body to absorb one kind of ray, and transmit another through it, we do not know, nor is it likely that any knowledge will ever be acquired respecting it. The speculations of Delaval, accounting for the colours given by dyestuffs by the size of the colouring particles, appear to us altogether unfounded, and quite inapplicable to the subject under discussion.

Nature of colour and dye stuffs.

Silk and wool dye better than cotton and linen.

With respect to the aptitude of being dyed, and the brilliancy of the colours thus communicated, there is found to be very great difference in different tissues. Animal substances are much more easily dyed than vegetable substances. Of animal substances, *silk* receives colour, and the shades given are brighter and more beautiful than those which can be imbibed by any other tissue. Woollen cloth is also very fit for being dyed, and receives very brilliant colours with avidity, though in this respect it is inferior to silk. Cotton and linen are much more difficult to dye, and cannot be made to imbibe such brilliant colours as silk or woollen. Thus the rich scarlet given to cloth by the combined action of cochineal and the oxide of tin, has never been communicated to cotton cloth or linen. The Turkey-red dye, which is by far the finest and most permanent red that has ever been communicated to cotton cloth, is a crimson, or rather a crimson with a shade of brown. It has not the least approach to a scarlet.

Upon what this difference between animal and vegetable bodies in the capacity of receiving colours depends, we do not know. Both woollen and silk contain a notable quantity of azote among their constituents, while this principle is altogether wanting in cotton and linen. How far the property of easy dyeing depends upon the presence of azote it is impossible to say; but it is the only chemical difference in their constitution that can in the present state of our knowledge be pointed out. Both cotton and flax, so far as their chemical characters have been examined, are precisely similar in their properties to *lignin* or the woody fibres of trees, supposing them deprived of all their foreign ingredients. Now the constituents of lignin are as follows, according to the analysis of Prout.

Carbon	50·00
Hydrogen	5·55
Oxygen	44·45
	100·00

This is proportional to

3 atoms carbon	2·25
2 atoms hydrogen	0·25
2 atoms oxygen	2·00
	4·5

Hence these substances (cotton and flax) must either be composed of three atoms carbon, two atoms hydrogen, and two atoms oxygen, or of some multiple of these numbers. How many atoms go to the formation of an integrant particle of cotton or flax cannot be known till some substance be discovered with which they are capable of entering into definite combinations.

The only attempt to determine the atomic constituents of silk and wool is that of Dr Ure, according to whom their composition is as follows.

	Silk.	Wool.
Azote	11·33	12·3
Carbon	50·69	53·7
Hydrogen	3·94	2·8
Oxygen	34·04	31·2
	100·00	100·0

These are equivalent to the following atomic numbers.

	Silk.	Wool.
Azote	13 atoms	14 atoms.
Carbon	135	143 ......
Hydrogen	63	45 ......
Oxygen	68	62 ......

But a comparison between these two sets of bodies will be made with more advantage if we represent the number of atoms of the other constituents of each upon the supposition that the atoms of carbon in each is the same, or 66. On this supposition the composition will stand as follows.

	Lignin.	Silk.	Wool.
Azote	0 atoms	6·3 atoms	6·5 atoms.
Carbon	66	66·0	66·0 ......
Hydrogen	44	30·8	20·7 ......
Oxygen	44	33·2	28·5 ......

If the analyses of these bodies constituted a near approximation to the truth, it would follow from a comparison of them: 1. That in lignin the hydrogen and oxygen exist in the proportions which constitute water, while in silk there exists an excess of oxygen, and in wool this excess is still greater. 2. In lignin there is no azote, whereas in silk and wool the atoms of azote amount to about one tenth of the atoms of carbon. 3. The atoms of hydrogen in silk are to those in lignin as three to four, and in wool as two to four; so that lignin contains twice as much hydrogen as wool does. 4. In silk the atoms of oxygen are to those in lignin very nearly as three to four; but in wool the number of atoms of oxygen is to that in lignin rather in a less ratio than that of three to four.

These facts lead us but a very little way in discovering the difference between the nature of silk and wool, and that of cotton and flax; but they contain all the information which chemistry at present is able to furnish. We shall now state, in the following sections, the differences which have been observed in the mechanical structure of these different substances.

SECT. I.—*Of Wool.*

Wool, which is well known as the covering of sheep, derives its value from the length and fineness of its filaments. The filaments of wool are considerably elastic, for they may be drawn out beyond their usual length, and when the force is removed, they recover it again. The surface of the filaments of wool or hair is not perfectly smooth; for although no roughness or inequality can be discovered by the microscope, yet they seem to be formed of small laminæ placed over each other in a slanting direction, from the root of the filament towards its point, resembling the arrangement of the scales of a fish, which cover each other from the head of the animal to its tail; or perhaps they consist of zones placed over each other,

Substances to be coloured.

as is observed in the horns of animals. This peculiarity of structure of the filaments of hair and wool is proved by a simple experiment. If a hair be laid hold of by the root in one hand, and drawn between the fingers of the other hand, from the root towards the point, scarcely any friction or resistance is perceived, and no noise is heard; but if it be grasped by the point, and passed in the same manner between the fingers from the point towards the root, a resistance is felt, and a tremulous motion is perceptible to the touch, while the ear is sensible to a slight noise. Thus it appears, that the texture of the surface of hair or wool is not the same from the root towards the point, as it is from the point towards the root. This is further confirmed by another experiment. If a hair be held between the thumb and fore finger, and they are rubbed against each other in the longitudinal direction of the hair, it acquires a progressive motion towards the root. This effect depends not on the nature of the skin of the finger, or on its texture, for if the hair be turned, and the point placed where the root formerly was, the motion is reversed, that is, it will still be towards the root.

Felting.

On this peculiarity of structure, which was observed by M. Monge, depend the processes of felting and fulling, to which hair and wool are subjected for different purposes. In the process of felting, the flocculi of wool are struck with the string of the bow, by which the filaments are separately detached, and dispersed in the air. These filaments fall back on each other in all directions on the table, and when a layer of a certain thickness is formed, they are covered with a cloth, on which the workman presses with his hands in all parts. By this pressure the filaments of wool are brought nearer to each other; the points of contact are multiplied; the progressive motion towards the root is produced by the agitation; the filaments entangle each other; and the laminæ of each filament taking hold of those of the other filaments, which are in an opposite direction, the whole is retained in the state of close contexture.

Fulling.

Connected with this operation is that of fulling. The roughness on the surface of the filaments of wool, and their tendency to acquire a progressive motion towards the root, produce considerable inconvenience in the operations of spinning and weaving. These inconveniences are obviated by covering the filaments with a coat of oil, which fills up the cavities, and renders the asperities less sensible. When these operations are finished, the stuff must be freed from the oil, which would prevent it from taking the colour with which it is to be dyed. For this purpose it is taken to the fulling-mill, where it is beaten with large beetles, in a trough of water, through which clay has been diffused. The clay unites with the oil, which being thus rendered soluble in the water, is carried off by fresh portions of water, conveyed to it by proper apparatus. In this way the stuff is scoured; but this is not the sole object of the operation. By the alternate pressure of the beetles, an effect similar to that of the hands in the operation of felting is produced. The filaments composing a thread of warp or woof, acquire a progressive motion, are entangled with the filaments of the adjoining threads, those of the latter into the next, and so on, till the whole threads are felted together. The stuff is now contracted in all its dimensions, and, participating both of the nature of cloth and of felt, may be cut without being subjected to ravel; and, when employed to make a garment, requires no hemming. In a common woollen stocking web, after this operation, the stitches, when one happens to slip, are now no longer subject to run, and the threads of the warp and woof being less distinct from each other, the whole stuff is thickened, and forms a warmer clothing.

Substances to be coloured.

Importance of wool.

The various manufactures of which wool constitutes the basis are justly regarded as among the most important to man in civilized society. Accordingly, the production of fine wool, and the causes which retard or improve the breed of sheep from which it is obtained, have greatly occupied the attention of economists and philosophers in our own, as well as in other countries. The wool of different breeds of sheep, in different countries, it is well known, possesses very different qualities, both with regard to the fineness of the filament, and the colour. Some is of a white or yellow, and some of a reddish and black colour. Excepting the wool of the breed of sheep in Andalusia, the Spanish wool was formerly all of a brownish-black colour. This was preferred by the native Spaniards; and even at this day, the dress of some religious orders in Roman Catholic countries consists of cloth manufactured from this wool, and retaining its natural colour. But for the purposes of dyeing, white wool is now always preferred, because it is found susceptible of receiving better and more durable colours.

Scouring.

Wool is naturally covered with a kind of grease or oil, which is found to preserve it from insects or moths, and on this account this greasy matter is not removed, or the wool is not scoured, till it is to be dyed or spun.[1] The process for scouring wool is the following: It is put for about a quarter of an hour into a kettle, with a sufficient quantity of water, to which a fourth part of putrid urine has been added. It is then heated to such a degree as the hand can bear, occasionally stirred, and, after being taken out, is allowed to drain. It is then put into a basket, and exposed to a stream of running water, and moved about till the grease is so completely separated that it no longer renders the water turbid. After being drained, it is sometimes found to lose by this operation above one fifth of its weight. It is almost unnecessary to observe, that the more carefully and completely this process is performed, the better the wool is fitted to receive the colouring matter. Our chemical readers will readily perceive the nature of the changes which are effected in this process of scouring. The ammonia, or volatile alkali, which exists in the urine, combines with the oil of the wool, and forms a soap, which being soluble in water, is dissolved and carried off.

Dyeing.

Wool is either dyed in the fleece, or after it is spun into threads, or when it has been manufactured into cloth. For the purpose of forming cloths of mixed colours, it is dyed before it is spun; for the purposes of tapestry, it is dyed in the state of thread; but most commonly it is subjected to this process after it has been manufactured into cloth. In these different states the quantity of colouring matter which is taken up is very different. The proportion is largest when it is dyed in the fleece, because then the filaments being more separated, a greater surface is exposed to the action of the colouring particles. For a similar reason the quantity of colouring matter taken up is greater when in the state of thread or yarn, than when it is formed into cloth. But cloths themselves must vary greatly in this respect, according to their different qualities. Their different degrees of fineness, or closeness of texture, will produce considerable variations; and besides, the difference in the quantity and dimensions of the substances to be dyed, the different qualities of the ingredients employed in the process, and the different circumstances in which it is performed, should be a caution against trusting to precise quantities, regulated by weight or measure, which are recommended according to general rules. According to the fineness of the texture of the wool, and the nature of the colouring matter employed, it is found to be more or less penetrated with this matter. The coarse wool from the thighs and tails of some sheep receives colours with difficulty, and the finest cloth is never completely penetrated with the scarlet dye. The interior of the cloth appears always, when cut, of a lighter shade, and sometimes even white.

---

[1] According to an observation of Reaumur, rubbing any stuff with greasy wool is sufficient to preserve it from moths.

Sect. II.—*Of Silk.*

Origin.

Silk, which forms the basis of one of the richest and most splendid parts of dress among the wealthy and luxurious in civilized society, is the production of different species of insects. The *phalæna bombyx*, or silk-worm, which is a native of China, attracted the attention of mankind in that country from the earliest ages. The honour of having first collected and prepared silk from the cocoons or balls in which it is wound up by the insect, during its metamorphosis, is ascribed by the Chinese historians to the wife of an emperor. The *phalæna atlas*, Lin. which is also a native of China, is said to form larger cocoons, and to yield a stronger silk. The silk-worm was first carried from China to Hindustan, and afterwards to Persia. Silk seems not to have been known to the Greeks or Romans till the time of Augustus. Its nature and origin were little understood; and for many ages it was so scarce that it could only be purchased at a price which was equal to its weight in gold. The emperor Aurelian, it is said, from a principle of economy, resisted the urgent solicitations of his empress, who wished to have a silken robe, alleging the extravagance of the expense. About the middle of the sixth century, two monks returned from India to Constantinople, and brought with them a considerable number of silk-worms, with instructions for managing and breeding them, as well as for collecting, preparing, and manufacturing the silk. Establishments were thus formed at Corinth, Athens, and other parts of Greece. The crusades, which greatly contributed to the diffusion of different kinds of knowledge, by the intercourse which took place between different countries, proved useful in disseminating the knowledge of rearing the silk-worm, and preparing and manufacturing its valuable productions. Roger, king of Sicily, about the year 1130, returning from one of these frantic expeditions, brought with him from Athens and Corinth several prisoners, who were acquainted with the management of silk-worms and the manufacturing of silk. Under their superintendence manufactories were established at Palermo and Cagliari in Sicily. This example was soon adopted and followed in different parts of Italy and Spain. In the time of James I. an attempt was made to establish the silk-worm in England. For this purpose the culture of the mulberry-tree, on which the insects feed, was strongly recommended by that prince to his subjects; but the attempts which were made have been hitherto unsuccessful.

Scouring.

The fibres of silk are covered with a coating or natural varnish of a gummy nature. To this are ascribed its stiffness and elasticity. Besides this varnish, the silk which is usually met with in Europe is impregnated with a substance of a yellow colour; and for most of the purposes to which silk is applied, it is necessary that it should be deprived both of the varnish and of the colouring matter. On this account it must be subjected to the operation of scouring; but for silks which are to be dyed this process should not be carried so far as for those which are merely to be whitened; and different colours, it is observed, require different degrees of this operation. The quantity of soap constitutes the chief difference. A hundred pounds of silk boiled in a solution of twenty pounds of soap for three or four hours, adding new portions of water during the evaporation, are sufficiently prepared for receiving common colours. For blue colours, the proportion of soap must be increased; and scarlet, cherry colour, &c. require a still greater proportion, for the ground must be whiter for these colours.

Silk which is to be employed white must undergo three operations. In the first the hanks are immersed in a hot but not boiling solution of thirty pounds of soap to a hundred of silk. When the immersed part is freed from its gum, which is known by its whiteness, the hanks are shaken over, as the workmen term it, so that the part which was not previously immersed may undergo the same operation. They are then wrung out as the process is completed. In the second operation the silk is put into bags of coarse cloth, each bag containing twenty or thirty pounds. These bags are boiled for an hour and a half in a solution of soap prepared as before, but with a smaller proportion of soap; and, that they may not receive too much heat by touching the bottom of the kettle, they must be constantly stirred during the operation. The object of the third operation is to communicate to the silk different shades, to render the white more agreeable. These are known by different names, as China-white, silver-white, azure-white, or thread-white. For this purpose a solution of soap is also prepared, of which the proper degree of strength is ascertained by its manner of frothing by agitation. For the China-white, which is required to have a slight tinge of red, a small quantity of anotta is added, and the silk is shaken over in it till it has acquired the shade which is wanted. In other whites a blue tinge is given by adding a little blue to the solution of soap. The azure-white is communicated by means of indigo. To prepare the azure, fine indigo is well washed two or three times in moderately warm water, ground fine in a mortar, and boiling water poured upon it. It is then left to settle, and the liquid part only, which contains the finer and more soluble parts, is employed.

Some use no soap in the third operation; but when the second is completed, they wash the silks, fumigate with sulphur, and azure them with river water, which should be very pure. But all these operations are not sufficient to give silk that degree of brightness which is necessary, when it is to be employed in the manufacture of white stuffs. For this purpose it must undergo the process of sulphuration, in which the silk is exposed to the vapour of sulphur; for an account of which see Bleaching. But before the silk which has been treated in this way is fit for receiving colours, and retaining them in their full lustre, the sulphur which adheres to it must be separated by immersion and agitation for some time in warm water, otherwise the colours are tarnished and greatly injured.

It has long been an object of considerable importance to deprive silk of its colouring matter, without destroying the gum, on which its stiffness and elasticity depend. A process for this purpose was discovered by Beaumé, but as it was not made public, others have been led to it by conjecture and experiment. The following account, given by Berthollet, is all that has transpired concerning this process. A mixture is made with a small quantity of muriatic acid and alcohol. The muriatic acid should be in a state of purity, and particularly should be entirely free from nitric acid, which would give the silk a yellow colour. In the mixture, thus prepared, the silk is to be immersed.

One of the most difficult parts of the process, espe-

Su ances be co ured.

cially when large quantities are operated upon, is to produce a uniform whiteness. In dyeing the whitened silk, there is also considerable difficulty to prevent its curling, so that it is recommended to keep it constantly stretched during the drying. The muriatic acid seems to be useful in this process, by softening the gum, and assisting the alcohol to dissolve the colouring particles which are combined with it. The alcohol which has been impregnated with the colouring matter may be again separated from it and purified, that it may serve for future operations, and thus render the process more economical. This may be done by means of distillation, with a moderate heat, in glass or stoneware vessels.

Al ing.

The preparation with alum is a very important preliminary operation in the dyeing of silk. Without this process few colours would have either beauty or durability. Forty or fifty pounds of alum, previously dissolved in warm water, are mixed in a vat with forty or fifty pailfuls of water; and to prevent the crystallization of the salt, the solution must be carefully stirred during the mixture. The silk being previously washed and beetled, to separate any remains of soap, is immersed in this alum liquor, and at the end of eight or nine hours is wrung out, and washed in a stream of water. A hundred and fifty pounds of silk may be prepared in the above quantity of liquor; but when it begins to grow weak, which may be known by the taste, twenty or twenty-five pounds of dissolved alum are to be added, and the addition repeated till the liquor acquires a disagreeable smell. It may then be employed in the preparation of silk intended for darker colours, till its whole strength is dissipated. This preparation of silk with alum must be made in the cold; for when the liquor is employed hot, the lustre is apt to be impaired.

Sect. III.—*Of Cotton.*

O in.

Cotton is the down or wool contained in the pods of a shrubby plant, which is a native of warm climates. Of this genus of plants (*Gossypium*, Lin.) there are four species, one of which only is perennial; the other three are annual plants; but of these there are many varieties, occasioned by the difference of soil or temperature in which they are produced. The principal differences among cottons consist in the length and firmness of the filaments, and in their strength and colour.

St cture.

The peculiar structure of the fibres of cotton is not well known. According to the microscopic observations of Leeuwenhoeck, they have two sharp sides, to which are ascribed the irritation and inflammation of wounds and ulcers when they are dressed with cotton instead of lint. This peculiarity of structure, it is also supposed, may occasion some difference in the conformation and number of the pores, on which alone the disposition of cotton to admit and retain colours better than linen seems to depend. In this respect, however, it is inferior to wool and silk, because, on account of its vegetable nature, its affinity for colouring matter is less powerful.

H a less af ity th wool fo olour- in atter.

It is well known that silk, cotton, and linen have a weaker affinity for colouring matter than wool. Le Pileur d'Apligny attempts to explain this by supposing that the pores of these substances are smaller than those of wool, and that the colouring particles enter them less easily and freely. But according to the observation of Dr Bancroft, the reverse of this seems to be the fact; for there is little difficulty in making silk, cotton, and linen imbibe colouring matter, even when it is applied cold, without any artificial dilatation of the pores, which is always necessary in the dyeing of wool. The only real difficulty is to make them retain the colours after the matter has been imbibed; because being admitted so readily into their undilated pores, the particles cannot be afterwards compressed and retained by the contraction of these pores, as is the case with wool. It requires double the quantity of cochineal which is necessary for wool to communicate a crimson colour to silk; a certain proof that it can take up a greater quantity, and consequently that the pores are sufficiently large and accessible. Unbleached cotton is always preferred for dyeing Turkey red, because in this state the colour is found to be most permanent; and this is ascribed to the pores or interstices being less open than after it has undergone the process of bleaching. The same thing is observed of raw or unscoured silk. It is found to combine more easily with the colouring matter, and to receive a more permanent colour in this state, than after it has been scoured and whitened. "The openness of cotton and linen," says Dr Bancroft, "and their consequent readiness to imbibe both colouring particles and the earthy or metallic bases employed to fix most of them, are circumstances upon which the art of dyeing and calico-printing is in a great degree founded."[1] But is not this too mechanical an explanation of the phenomenon? Might it not rather be alleged that it is owing to a difference of affinities which exists between the particles of colouring matter and the substance which is separated from the silk or cotton by the process of bleaching or scouring? This substance probably acts the part of a mordant; and having a stronger affinity for the stuff and for the colouring matter than the stuff has for the latter, the colour communicated is more durable when silk or cotton is dyed in the unbleached or unscoured state.

Substances to be coloured.

Preparations for dyeing.

To prepare cotton stuffs for receiving the dye, several operations are necessary. It must first undergo the process of scouring. By some it is boiled in sour water, or in alkaline ley. It should be kept boiling for two hours, then wrung out, and rinsed in a stream of water till the water comes off clear. The stuffs to be prepared should be soaked for some time in water, mixed with not more than $\frac{1}{50}$th part of sulphuric acid, and then carefully washed in a stream of water, and dried. In this operation the acid combines with a portion of calcareous earth and iron, which would have interrupted the full effect of the colouring matter in the process of dyeing.

Aluming.

Aluming is another preliminary process in the dyeing of cotton. The alum is to be dissolved in the manner already described in preparing silk. Each pound of cotton stuff requires four ounces of alum. By some a solution of soda, about $\frac{1}{16}$th part of the alum, and by others a small quantity of tartar and arsenic, are added. The thread is to be impregnated by working it in small quantities with this solution. The whole is then put into a vessel, and the remaining part of the liquor is poured upon it. In this state it is left for twenty-four hours, after which it is removed to a stream of water, and allowed to remain for an hour and a half, or two hours, to extract part of the alum. It is then to be washed. By this operation cotton is found to gain an addition of about $\frac{1}{40}$th part of its weight.

Galling.

The operation of galling is another preparatory process in the dyeing of cotton stuffs. The quantity of astringent matter employed must be proportioned to its quality, and the amount of the effect required. Powdered galls are boiled for two hours in a proportion of water, regulated by the quantity of thread to be galled. This solution being reduced to such a temperature as the hand can bear, is

---

[1] *Philosophy of Permanent Colours*, p. 71.

Substances to be coloured.

divided into a number of equal parts, that the thread may be wrought pound by pound. The whole stuff is then put into a vessel, and the remaining liquor poured upon it, as in the former process. It is then left for twenty-four hours if it is to be dyed black, but for other colours twelve or fifteen hours are found sufficient. It is then wrung out and dried.

In the galling of cotton stuffs, which have already received a colour, the precaution should be observed of performing this operation in the cold, otherwise the colour is subject to injury.

Berthollet informs us, that cotton which had been alumed acquired more weight in the galling than that which had not previously undergone that process; for although alum adheres but in small quantities to cotton, it communicates to it a greater power of combining both with the astringent principle and with the colouring particles. This, we may add, may be considered as a good instance of the action of intermediate affinities, and of the advantage to be derived to the art of dyeing, from investigating and observing this action.

Sect. IV.—*Of Flax.*

Origin. Flax and hemp nearly resemble each other in their general properties; and, so far as relates to the process of dyeing, what is said of the one may be applied to the other. Flax or lint is obtained from the bark of *Linum usitatissimum*, and hemp from that of *Cannabis sativa*.

Watering. Before flax is properly prepared to receive the dye, it must be subjected to several processes. One of the most important is that of watering, by which the fibrous parts of the plant are separated, and brought to that state in which they can be spun into threads. As the quantity and quality of the product depend much on this preliminary operation, it becomes of the greatest consequence that it be properly conducted. During this process carbonic acid and hydrogen gas are given out. The extrication of these gases is owing to a glutinous juice, which holds the green colouring part of the plant in solution, and which is the medium of union between its cortical and ligneous parts, undergoing a certain degree of putrefaction. This substance seems to resemble the glutinous part, which is held dissolved in the juice obtained from plants by pressure; is separated from the colouring particles by means of heat; readily becomes putrid; and by distillation affords ammonia. But although it is held in solution with the expressed juice, it would appear that it cannot be separated from the cortical parts completely by means of water; and hence it happens that hemp or flax watered in too strong a current has not the requisite softness and flexibility. But, on the other hand, if the water employed in this operation be stagnant and in a putrid state, the hemp or flax becomes of a brown colour, and loses its firmness. In the one case the putrefactive process is interrupted; in the other it is continued too long and carried too far. This process, therefore, is performed with the greatest advantage in places near the banks of rivers, where the water may be changed so frequently as to prevent such a degree of putrefaction as would be injurious to the flax, as well as prejudicial to the workmen, from noxious exhalations; and at the same time not so frequently as to retard or interrupt those changes which are necessary for rendering the glutinous substance soluble in water.

By the process of watering flax, and by drying before and after that process, the green-coloured particles undergo a similar change to that which is observed in the green substance of the plants exposed to the action of air and light. The next part of the process, therefore, after watering, is to spread it out upon the grass, and thus expose it for some time to the air and sun. By this means the colour of the lint is improved, and the ligneous part becomes so brittle that it is easily separated from the fibrous part. This operation, as is well known, is usually performed by machinery.

The fibres of lint possess no perceptible degree of elasticity, and they appear to be perfectly smooth. No roughness or inequality can be detected by the feel, and no asperities can be perceived, even with the assistance of the microscope. Experience shows, that it produces no irritation on wounds or sores which are dressed with it, as is known to happen from a similar application of cotton stuffs.

Flax which is intended for dyeing must be subjected to a similar series of operations with cotton, in the different processes of scouring, aluming, and galling. A repetition of the mode of performing these operations is therefore unnecessary.

CHAPTER III.

OF MORDANTS.

The term mordant is applied by dyers to certain substances with which the cloth to be dyed must be impregnated, otherwise the colouring matters would not adhere to the cloth, but would be removed by washing. Thus the red colour given to cotton by madder would not be fixed, unless the cloth were previously steeped in a solution of a salt of alumina. It has been ascertained that the cloth has the property of decomposing the salt of alumina, and of combining with and retaining a portion of alumina. The red colouring principle of the madder has an affinity for this alumina, and combines with it. The consequence is, that the alumina being firmly retained by the cloth, and the colouring matter by the alumina, the dye becomes fast, or cannot be removed by washing the cloth with water, even by the assistance of soap, though simple water is sufficient to remove the red colouring matter from the cloth, unless the alum mordant has been previously applied.

The term *mordant* (from the Latin word *mordere*, to bite) was applied to these substances by the French writers on dyeing, from a notion entertained by them that the action of the mordants was mechanical; that they were of a corrosive or biting nature, and served merely to open pores in the fibres of the cloth, into which the colouring matter might insinuate itself. And after the inaccuracy of this notion was discovered, and the real use of mordants ascertained, the term was still continued, as sufficiently appropriate, or rather as a proper name, without any allusion to its original signification.

The term *mordant*, however, is not limited to those substances merely which serve, like alumina, to fix the colours. It is applied also to certain substances, which have the property of altering the shade of colour, or of brightening the colour, as it is called. Thus *cream of tartar* is usually called a mordant, because when chloride of tin is used, as is the case in the red dye upon silk or woollen, the addition of cream of tartar is necessary, not merely to brighten the colour, but to cause its equable application upon the cloth; for when the tartar is omitted, we observe that the shade is very unequal upon different parts of the surface, some spots being much darker and some much lighter than others. We believe that tartar acts chiefly, if not entirely, by forming a double salt with the chloride of tin, from which the tin is not liable to be partially precipitated. The consequence of this is, the equal distribution of the tin through the whole liquid, and the consequent equality of its application on the cloth. For the depth of the shade depends upon the proportion of tin fixed upon the cloth. Berthollet has proposed to distinguish those substances which are employed to alter the shade of colour from the mordants strictly so called, by giving them the name of *alterants*.

The mordants employed by dyers are but few in number. Alumina, the oxides of tin, the protoxide of lead, the black oxide of copper, and the infusion of nutgalls, constitute almost the whole of them. The peroxide of iron and the sesquioxide of manganese have also a strong affinity for cloth, especially for cotton cloth, and are frequently employed; but they serve at once the purpose of mordants and colouring matters. We believe also that in one important process for giving a fine red to cotton, what is usually called *the Turkey-red dye*, the *margarate of potash* constitutes an indispensable mordant.

Let us take a view of these different mordants in succession.

1. *Alumina.*—This is a soft, white, tasteless powder, insoluble in water, but soluble in acids, and constituting sweet-tasted and astringent salts, which have the property of reddening vegetable blues. These salts are soluble in water, but very few of them are capable of crystallizing. Of all the salts of alumina, the most important is *alum*, the nature and properties of which have been described in another part of this work. See ALUM

H used.

It is a double salt, composed of three integrant particles of sulphate of alumina united to one integrant particle of sulphate of potash or sulphate of ammonia and twenty-five integrant particles of water. The ammoniacal alum is less soluble in cold water than the potash alum; but both kinds are sufficiently soluble in hot water. Such is the affinity of alumina for woollen or silk stuffs, that when they are plunged into a solution of alum, the alumina leaves the sulphuric acid with which it was united, and combines with the fibres of the cloth. The affinity of alumina for cotton or linen, though considerable, is not so great as its affinity for wool or silk. On that account the cotton dyers and calico printers find it requisite to combine the alumina, before using it as a mordant, with a weaker acid than the sulphuric. The *acetic* is the one which has been made choice of, and the acetate of alumina is prepared by the following process: Three parts of alum and one part of acetate of lead are dissolved in eight parts of hot water. There is then added one eighth of a part of potash and as much chalk. The reason of the addition of the potash and the chalk is, that one part of acetate of lead is not sufficient to decompose three parts of alum. These substances prevent the residual alum from crystallizing, by decomposing it. The proper quantities of these salts which the dyers ought to employ are six parts of alum and seven parts of sugar of lead. These proportions would just convert the sulphate of alumina of the alum into acetate of alumina, without altering the sulphate of potash.

The wool or silk is put into a hot solution of alum, and the cotton into a hot solution of acetate of alumina, and passed through the liquid till a sufficient quantity of the alumina has combined with the fibres of the cloth. It is then wrung out, washed, and dried. The alumina remains firmly adhering to the cloth, and cannot be removed by washing, bleaching, or any of the processes to which such cloths are usually subjected.

Q ntity of umina w h adhe s to co n.

In order to form some notion of the quantity of alumina fixed upon cloth by the aluming process, the writer of this article made the following experiments: A quantity of cotton cloth was procured, such as is sometimes used for making light dresses of Turkey red. Of this, 1000 grains were burnt, and the ashes being reserved and analyzed, were found to contain 0·4 grain of alumina. 1000 grains of the same cloth which had been dyed Turkey red, and of course subjected to the aluming process, were burnt, and the ashes subjected to a chemical analysis. The alumina contained in them weighed eight grains. Hence 7·6 grains of this matter had combined with the cloth in the process of aluming.

The length of 1000 grains of the undyed cotton cloth was one yard five and two-third inches, and its breadth thirty-three inches. The length of 1000 grains of the Turkey red cloth was one yard and six inches, with a breadth of thirty-three inches. The two pieces of cloth, therefore, were very nearly of a size. We see that the dyed cloth had been stretched a very little during the processes to which it had been subjected. Thus it appears that a surface of cloth amounting to 1386 square inches, or rather 2772 square inches (as both sides of the cloth had been equally subjected to the aluming process), had combined with 7·6 grains of alumina, or every square inch of the cloth had combined with 0·0027 grains ($\frac{1}{370}$th grain nearly) of alumina. Small as this quantity may appear, it was sufficient to fix the red colouring principle of madder, and to constitute a very deep and beautiful dye.

A very pale shade of red is sometimes given to a portion of the cloth, which has a beautiful effect when contrasted with the deep Turkey-red dye. This is produced by limiting the quantity of alumina applied to the parts which are to be light red. In fact, no alum mordant whatever is applied to the parts which are to be light red; but they get a little during the steps taken to remove the excess of aluminous mordant, which has been applied to the parts that are to get the deep-red colour.

To ascertain the quantity of alumina which was sufficient to fix the light-red colour, the writer of this article got a portion of the same cotton cloth formerly operated on, dyed of the light-red colour. 1000 grains of this cloth being burnt, and the ashes analyzed, were found to contain 0·8 grain of alumina. Subtracting the 0·4 grain of alumina which 1000 grains of the undyed cloth contained, there remains 0·4 grain for the quantity communicated during the aluming process. These 1000 grains of cloth constituted a length of one yard and ten two-third inches. The breadth was thirty-two inches. Its surface (reckoning both sides) constituted $2986\frac{2}{3}$ square inches. So that every square inch of surface had combined with 0·00012 grains of alumina, or less than $\frac{1}{8000}$th of a grain. Yet this quantity of alumina, small as it is, was essential to the permanence of the dye; for when unalumed cloth was dyed with madder, the colour was speedily and easily washed out by water; but the light-red Turkey-red dye was perfectly fixed.

These facts are sufficient to show us the very small size of a particle of alumina. Were only 1000 particles of this substance fixed upon the square inch of surface of cloth, the weight of a particle of alumina would not exceed the millionth part of a grain. But that the number far exceeds 1000 is evident from this, that when we examine the surface of the cloth with a microscope, the red colour does not appear in spots, but is equally spread over the whole cloth. Many thousand particles of alumina upon the square inch would be requisite to produce this effect.

The aluming and the dyeing are sometimes given to the cloth together; but more frequently the aluming precedes, and the dyeing follows after the cloth has imbibed the mordant and been washed and dried.

2. *Tin.*—Of all the metallic oxides, those of tin are the most useful as mordants. They form, with acids, salts very easily decomposed; and the fibres of cloth have an affinity so strong for these oxides, that they readily withdraw them from their saline combinations, and unite with them. Tin forms two different oxides with oxygen. The protoxide is *black*, but the peroxide is yellow, and sometimes also white.

The tin mordants are formed by dissolving tin in muriatic acid. There are two chlorides of tin, as the combinations of that metal with chlorine are called. These are, the protochloride and the perchloride. The protochloride, when anhydrous, is a gray solid, with a pearly lustre; but when it is formed by dissolving tin in muriatic acid, it crystallizes in large oblique four-sided prisms, with one edge usually replaced by a tangent plane. The colour is white, with somewhat of the diamond lustre. The taste is acid, acrid, and disagreeable. When recently formed they dissolve in water; but when kept they dissolve imperfectly, leaving a white matter behind, which is an oxide of tin, and the quantity of this insoluble oxide increases with the age of the crystals.

How prepared as a mordant.

Calico-printers form their tin mordant by dissolving tin directly in muriatic acid; but the silk and woollen cloth dyers employ aqua regia for the purpose. Indeed tin for the dyers was originally dissolved in weak nitric acid; but when this method is followed, almost the whole tin precipitates in the state of an oxide in a few days. To prevent this precipitation, they added a little common salt or sal ammoniac to the nitric acid in which the tin was to be dissolved. Hellot informs us that Baron claimed the merit of having been the first person who employed aqua regia at Carcassone to dissolve tin. The object in view was to prevent the precipitation of the oxide, which always happens when nitric acid alone is used for that purpose.

The dyer's ordinary solution of tin is made with the kind of nitric acid called single *aqua fortis*. It is capable of dissolving about the eighth part of its weight of granulated tin. For each pound of aqua fortis it is usual to add about two ounces of common salt or sal ammoniac, and a little water to moderate the action of the acid. Those solutions which have been made most slowly, and with the least separation of fumes or vapours, have been found to succeed best; showing clearly that it is the protochloride of tin that constitutes the proper mordant. Two ounces of grain tin are usually allotted to every pound of aqua fortis. The metal should be added at different times, waiting till one part is nearly dissolved before another is added, otherwise too much heat may be evolved, which would cause the solution to go on too rapidly. The quantity of water added should be about one half of that of the aqua fortis used; so that the solution, when completed, should contain about one thirteenth of its weight of tin. About 20 lbs. of such a solution is required to die 100 lbs. of woollen cloth a full cochineal scarlet.

The process usually followed is this: Supposing 100 pounds weight of cloths intended to be died; ten pounds of cream of tartar are put into a suitable dyeing vessel of pure block tin,[1] with a sufficient quantity of clean soft water, and six or eight ounces of powdered cochineal. Immediately after this, ten or twelve pounds of the solution of tin are to be added, and when the mixture is nearly boiling hot, the cloth, previously completely wet, is put into the dyeing liquor, and turned through it by the winch, at first very rapidly, and afterwards slowly. This is to be continued for an hour and a half, after which the cloth is to be taken out and rinsed in clean water. By this first process the cloth has acquired a flesh colour. For the second or dyeing process the tin vessel is replenished with clean water. Five or six pounds of cochineal in powder are to be put into it, and well mixed by stirring it for a few minutes. After this the remaining part of the solution of tin is to be added; and the whole being well stirred, the cloth is to be put into the liquor, and turned very briskly through it, that both ends may receive an equal portion of the dye. After this it is turned more slowly for the space of half an hour, or until the dyeing liquor becomes exhausted, when the cloth is to be taken out, aired, and rinsed.

The process followed by the calico-printers for preparing the tin mordant is to dissolve tin in muriatic acid, by which a protochloride of tin is obtained. But Dr Bancroft found that, when a saturated solution of tin in muriatic acid was employed for dyeing woollen cloth scarlet, it had a corrosive effect on the cloth. He recommends a mixture of nitric and muriatic acid as a good solvent; and doubtless such a mixture would be cheaper and better than a solution of common salt or sal-ammoniac in nitric acid. Dr Bancroft found that a mixture of sulphuric and muriatic acid made a good solvent for the tin. Some farther experiments are still wanting to elucidate the best state of the tin mordant for the scarlet dye. We are of opinion that it is the protochloride of tin that constitutes the true mordant;[2] but some addition seems necessary to enable the fibres of the cloth to separate the oxide of the tin from the combination in which it exists, or rather to unite with the muriatic acid, when it is formed and disengaged by the decomposition of water, which obviously takes place, otherwise this acid, when evolved, will exert a corrosive action on the cloth.

The tartar is necessary to produce the scarlet colour. Without it the colour of the cochineal dye is crimson, or at most a rose colour. It doubtless acts principally by forming a double salt with the chloride of tin. But it must also convert a portion of the cochineal into a yellow dye; for scarlet is a compound colour, consisting of a great deal of red, mixed with a small quantity of yellow.

3. *Lead.*—We are not aware of the protoxide of lead being employed in any case as a mordant in dyeing silks or woollen cloth; but of late years it has been used as a mordant for cotton, to which the beautiful yellow given by means of chromic acid was to be communicated. For this purpose the lead is dissolved in nitric acid, or converted into nitrate of lead. This salt crystallizes in octahedrons, has a sweet and astringent taste, and dissolves readily in water. An aqueous solution of it thickened by gum is applied to those parts of the cloth which are to receive a yellow colour; or if the cloth has been already dyed red, a quantity of tartaric acid is mixed with the solution of nitrate of lead and gum, and after it has been applied and dried on the cloth, the piece is passed through water impregnated with a quantity of bleaching powder. The red colour is discharged; but the oxide of lead, which had united with the fibres of the cloth, still continues to adhere without alteration. The cloth is now passed through a solution of bichromate of potash. Those parts of it which contained the oxide of lead immediately decompose the bichromate; chromate of lead is formed and fixed upon the cloth, constituting a most beautiful and indelible yellow colour; or, by particular alterations in the process, this yellow colour may be changed to red, or to a very deep orange approaching red, and exceedingly beautiful.

4. *Copper.*—The black oxide of copper is employed as a mordant in giving a black colour to hats, or at least acetate of copper is employed in the process; and it is not easy to conceive any other purpose which such a salt can serve than contributing a portion of oxide of copper to act as a mordant.

5. *Galls.*—Nutgalls are excrescences which grow on

---

[1] Copper vessels are found to injure the colour, and therefore are not used.

[2] We do not mean that the protoxide of tin remains fixed on the cloth: it doubtless becomes peroxide. But the superior solubility of protochloride of tin fits it better for the purpose.

Excr cence on oak.

the branches of some species of oak, in consequence of the puncture of an insect, the *cynips quercus folii.* The best kind come from the Levant. They are nearly spherical bodies, with protuberances on the surface. There is a cavity within where the insect lodged, and a round hole from that central cavity to the surface, by which the insect, after it was hatched from the deposited egg, eat its way out. These nutgalls have a very astringent and austere taste. When digested in water they give that liquid a brown colour, and the taste which they themselves have. When such an infusion is mixed with a solution of sulphate of iron, it strikes a deep blue or black colour. Nutgalls, besides a considerable portion of woody fibre, contain a notable quantity of two peculiar vegetable substances, to which they owe their value as dyestuffs or mordants. These are *tannin* and *gallic acid.* The latter of these substances is easily obtained in a state of purity; the former with difficulty.

Cont ns tann

The infusion of nutgalls contains scarcely any thing else than a solution of tannin and gallic acid. If we evaporate the solution in a gentle heat to dryness, and digest the residue in sulphuric ether or absolute alcohol, the gallic acid will be dissolved, and the tannin will remain in a state of tolerable purity, only coloured brown by the action of the air. Tannin, when pure, is white while moist. It becomes yellow when dried even *in vacuo,* and by subsequent exposure to the air it becomes darker coloured. Its taste is excessively astringent and harsh; and it is distinguished by the property of striking a deep blue or black with the salts of iron. Tannin is easily altered in its nature by heat. Its constitution, as determined by the experiments of Berzelius, is as follows:

Carbon	52·69	to 52·49
Hydrogen	3·86	to 3·79
Oxygen	43·45	to 43·72
	100·00	100·00

This corresponds best with

7 atoms carbon	5·25
3 atoms hydrogen	0·375
4⅓ atoms oxygen	4·333
	9·958

Hence it is either composed of these atoms or of some multiple of them, most probably of

21 atoms carbon	15·75
9 atoms hydrogen	1·125
13 atoms oxygen	13·00
	29·875

This would make its atomic weight 29·875.

Tannin exists not merely in nutgalls, but in oak bark, in the wood of the oak, in the leaves, and in fact in every part of that tree; but the quantity of it is much greater in nutgalls than in any other part.

Tannin possesses the characters of an acid. It reddens vegetable blues, effervesces with the carbonates, and unites in definite proportions with the bases.

and lic acid

Gallic acid exists also as a constituent of nutgalls, and may be extracted from them by means of ether or absolute alcohol. Its colour is white, though it is apt, like tannin, to become yellow when exposed to the atmosphere, and seems indeed capable of being converted into tannin by exposure to too high a temperature. It is not nearly so soluble in water as tannin, and is distinguished by an acid taste instead of an astringent one. Like tannin, it strikes a black with the salts of iron. But the gallate of iron is readily distinguished from the tannate. The former is an exceedingly fine black powder, which precipitates very slowly, while the latter is a deep blue, which precipitates rapidly, has a coarse appearance, and becomes black when dry. The constituents of gallic acid, according to the analysis of Berzelius, are as follows:

Carbon	56·64
Hydrogen	5·00
Oxygen	38·36
	100·00

This corresponds with

7½ atoms carbon	5·625
4 atoms hydrogen	0·5
4 atoms oxygen	4·0
	10·125

Or, if we double the quantities to get rid of the half atom,

15 atoms carbon	11·25
8 atoms hydrogen	1·00
8 atoms oxygen	8·00
	20·25

In gallic acid the hydrogen and oxygen exist in the proportions which constitute water; but in tannin there is a surplus of oxygen. In gallic acid there is rather more hydrogen than in tannin.

How used as a mordant.

The great use to which the infusion of nutgalls is put in dyeing is to give a black colour when mixed with solution of sulphate of iron. When used in this way it perhaps is improperly named a mordant; for the oxide of iron is known to have a strong affinity for the fibres of cloth, and the tannin and gallic acid have a strong affinity for the oxide. Hence probably the way in which the black dye is fixed on silk and woollen cloth. There can be no doubt that the tannin, which is by far the most abundant ingredient, is the principal agent in striking the black with the sulphate of iron. But the gallic acid probably adds to the lustre, and improves the beauty of the colour.

In the Turkey-red process for giving a fixed red colour to cotton cloth by means of madder, steeping the cloth in infusion of nutgalls is an important part of the process, as without this the colour would be apt to want equality of shade in different parts of the cloth. In this process there can be no doubt that tannin acts the part of a mordant. The galling, in preparing the cloth for the Turkey-red dye, always precedes the alumina process. Whether it has the property of making the alumina more fixed on the cloth than it otherwise would be, or what other purpose it may serve, is not very well understood; but it is certain that the boiling of the cloth in a pretty strong infusion of galls is important. The infusion of galls is made by boiling twenty-five pounds of nutgalls in forty gallons of water, till four or five gallons are boiled or evaporated. The specific gravity of the infusion is 1·020; or sometimes the process is twice repeated, employing each time only twelve and a half pounds of nutgalls in forty gallons of water. The specific gravity of each infusion in that case is only 1·010.

Such is an account of the mordants at present employed in dyeing, and the way of using them. It is not always necessary to employ mordants in dyeing; some colouring matters adhere to the cloth without the presence of any intermediate substance. This is the case with the oxides of iron and manganese. It is the case also with indigo, and it was the case also with the colouring matter from the buccinum and purpura employed by the ancient Phœnician dyers in dyeing the celebrated purple, of which an account has been given in the first chapter of this treatise. To those colouring matters which adhere to the cloth of themselves Bancroft has given the name of *substantive* colours, while he distinguishes those that require a mordant by the name of adjective colours.

Mordants.

Effects of mordants on the colour.

Mordants have a very considerable effect on the colour; and by varying the mordant, very different colours, and a great variety of shades, may be obtained from the same colouring matter. Some mordants themselves may be considered as communicating a colour, without the addition of any colouring substance; and although, when the latter is added, a new set of affinities is brought into action, yet there is little doubt that the mordant also has a considerable share in fixing the shades of colour. Let us take an example in dyeing with cochineal. When the aluminous mordant is employed, the colour produced is crimson; but when the oxide of iron is substituted for the alumina, the colour obtained is black. The effect is obviously produced by a change in the action of the affinities between the colouring matter and the mordant, and the colouring matter and light. In the use of mordants, therefore, it is necessary to attend to their combined effects with the colouring matter employed, and, to be able to communicate particular colours to stuffs with any degree of certainty, to know the amount of that effect.

Even in the mode of applying mordants, the variety of shades may be greatly multiplied. Different effects, for instance, are produced by previously impregnating the stuff with the mordant, or by mixing it with the bath. Different effects also arise from using heat, or as the stuff is more or less rapidly dried; and this must appear to be the case, if we consider the different affinities which are in action, and the change on the action of these affinities in these different circumstances, as well as in others which can scarcely be appreciated. The combination of these substances which have an affinity for the stuff, and the decompositions which are the result of that combination, are greatly facilitated by the evaporation of the water or other liquid which held these substances in solution; because by its affinity, which is opposed to the action of the affinity between these substances and the stuff, the affinity of the latter produces a more limited effect. But in dyeing, the process should proceed slowly, that the substances may not be separated before their mutual affinities have begun to operate.

Considerable differences must be observed in the mode of employing the mordant, as the force of affinity between the stuff and the colouring matter is greater or less. When this affinity is strong, the mordant and the colouring substance may be mixed together; the compound thus formed immediately enters into combination with the stuff. But if the affinity between the stuff and the colouring particles be weak, the compound formed of the latter and the mordant may separate, and a precipitation take place, before it can be attached to the stuff; and hence it is in these cases that the mordant, which is to serve as the medium of union between the stuff and the colouring matter, must be combined with the former, before the application of the latter. It is from these differences that different processes must be followed in fixing colouring matters on animal and vegetable productions; as, for instance, in dyeing wool or silk black, or with cochineal.

In estimating the effects of mordants, and in judging of the most advantageous manner of applying them, it is necessary to attend to the combinations which may be formed, either by the action of the ingredients of which they are composed, or by that of the colouring matter and the stuff. It is necessary also to take into consideration the circumstances which may tend to bring about these combinations with more or less rapidity, or that may render them more or less perfect. The action which the liquor in which the stuff is immersed may have, either on its colour or texture, must also be considered; and, to be able accurately to judge of the extent of this action, we must know the proportions of the principles of which the mordant is composed; which of these principles remains in an uncombined state in the liquor; and the proportion or quantity which is thus separated.

S ple C ars.

CHAPTER IV.

OF THE MODE OF DYEING SIMPLE COLOURS.

Dyers have divided colours into two classes, namely, *simple* and *compound* colours. The *simple* are produced by a single dyeing process, and cannot be obtained by mixing together different colours. The compound colours are obtained by mixing together any two of the dyestuffs which produce the simple colours. By this means two colours are given to the cloth at once; and the shade depends upon the proportions of each dyestuff employed.

The simple colours are five in number; namely, *red, yellow, blue, black,* and *brown.* The last of these may be considered also as a compound colour, as it may be formed by mixing the dyestuffs for two simple colours together. The compound colours are *orange, green, purple,* and *gray.* We shall in this chapter confine ourselves to the mode of dyeing the simple colours, dividing it into five sections, in each of which we shall treat of a simple colour.

Sect. I.—*Of Red.*

In treating of the red dye, the simplest method seems to be to give an account, in the first place, of the dyestuffs employed for dyeing red; and in the second place, to describe the methods followed by the dyer to give a red colour to silk, wool, cotton, and flax.

I.—*Description of the Dyestuffs.*

The principal colouring matters used in dyeing red are *madder, cochineal, kermes, lac, archil, carthamus, Brazil wood,* and *logwood.*

Cont s two c ur- ing m ters.

1. *Madder* is the root of a plant, the *rubia tinctorum,* which is cultivated in the south of Europe. There are two varieties, the *rubia cordifolia* and the *rubia peregrina.* It is this last which is cultivated in the south of Europe, and comes to us from the Levant. The roots are wiery, and very much branched. They have a red colour externally, but are yellow within. This plant was cultivated by the Greeks and Romans, and was employed in medicine, and also in dyeing, as Dioscorides and Pliny inform us. It was called *erythrodamus* and *vœrantia* by the Greeks, and *rubia* by the Romans. From the last Greek name is derived the French word *garance,* by which madder is distinguished in that language.

It is the woody portion of madder that is useful in dyeing: the bark and pith are comparatively of little value. Madder has been examined by many chemists; but Robiquet and Colin alone have succeeded in separating the red colouring matter, and in determining its properties. They have distinguished it by the name of *alizarin,* an appellation derived from *alizari,* by which madder is distinguished in the Levant.

Madder contains two colouring matters; one, which is yellow, is soluble in cold water; the other, the alizarin, is soluble only in boiling water. To the yellow colouring matter Kuhlmann has given the name of *xanthin.* This matter considerably injures the colour of the alizarin; hence the reason why cloth dyed with madder has at first a dull brownish-red colour, which it loses in proportion as the xanthin is removed.

Ali n how- tain

To obtain *alizarin,* Robiquet and Colin recommend the following process. Mix pounded madder with two thirds or with its own weight of concentrated sulphuric acid, and set the mixture aside for two or three days, taking care that heat is not evolved. All the other constituents of the madder, except the alizarin, are converted into charcoal; and should heat have been evolved, even the alizarin itself will be charred. Wash the black matter thus formed, to extract from it all the acid. What remains is a mixture of charcoal and alizarin Let it be dried and digested with a portion of cold alcohol, which will dissolve a fatty matter which it contains. Let it now be digested in boiling alcohol till all the alizarin is dissolved. Mix the alcoholic solutions with water, distil off the alcohol, and filter the residual liquor. The alizarin remains upon the filter in a state of purity. Various other processes for extracting alizarin have been given by Robiquet and Colin, and by Kuhlmann and Zenneck.[1] But for these we refer to the respective publications of these chemists. The process which we have given we consider as of easiest execution.

Its per-ties.

Alizarin is insipid, and destitute of smell. According to Zenneck, it possesses weakly acid properties; but Colin and Robiquet consider it as perfectly neutral. It sublimes easily in long flexible capillary needles, having an orange colour; but unless the subliming vessels be very low and flat, much of the alizarin is decomposed during the process. Two watch-glasses applied to each other, for example, answer very well as a subliming vessel. During the process the alizarin gives out an aromatic odour like that of benzoin. It is almost insoluble in cold water; but it is moderately soluble in boiling water, to which it communicates a rose-red colour. At the temperature of 54°, 212 parts of alcohol, of the specific gravity 0·83, dissolve one part of alizarin. At the same temperature sulphuric ether, of specific gravity 0·73, dissolves $\frac{1}{160}$th part of its weight of it. The alcoholic solution is red, that of ether yellow or orange. It is slightly soluble in bisulphide of carbon, oil of turpentine, naphtha, and the fat oils, communicating to these bodies a reddish-yellow colour. Chlorine has little action on it, yet it injures the colour a little, and makes it incline to yellow. Sulphuric acid dissolves it, and acquires at the same time a blood-red colour. Nitric and muriatic acid dissolve it, and slightly alter the shade of its colour. These acids, when dilute, do not dissolve it. With alkalies it forms soluble combinations, having a violet-red colour, which do not afford crystals. The alkaline carbonates dissolve it, assuming a violet colour. With the alkaline earths it forms precipitates, having a violet or lilac colour; with alumina a precipitate which is red or reddish-brown. With the metallic oxides it forms insoluble combinations, having a violet or reddish-brown colour.

It has a marked affinity for various animal matters. It dissolves in the white of an egg diluted with water; and if we coagulate the albumen by heat, the alizarin combines with it, leaving the liquid portion tinged yellow. Albumen, containing a portion of alizarin in solution, is precipitated by a solution of chloride of calcium; yet this salt does not precipitate uncombined albumen diluted with the same quantity of water. Phosphate of lime appears also to have a marked affinity for the colouring matter of madder. Indeed this is obvious, from the well-known fact, that the bones of animals which have taken for some time a quantity of madder mixed with their food, are tinged red.

Urine, when left in contact with madder, extracts from it the alizarin, and acquires a red colour, even when quite recent and acid. Milk is coloured yellow by madder, and red coagulated curd is deposited upon the madder. The solution of animal gelatin does not precipitate the red colouring matter of madder.

We are not aware that madder is employed in dyeing silk or wool, but it constitutes one of the most beautiful and fixed red dyes for cotton and linen, and for dyeing these substances it has been in use probably at least two thousand years. As the yellow colouring matter or *xanthin* is not used in dyeing, it seems unnecessary to give any account of it in this place.[2] It gives a very beautiful yellow colour, and might be employed in calico-printing, were it not that the extraction of it would cost too much money.

Nature of cochineal.

2. *Cochineal* is the name given to a small insect that inhabits the *cactus coccinilifera*, and three or four other species of cactus, upon which it remains immoveable, drawing its nourishment from the juices of the plant. The insect is called by entomologists *coccus cacti*. It is the female insect (which is without wings) that constitutes the dyestuff. The insect is small, having a kind of hemispherical back, crossed by numerous wrinkles, and of a dark reddish-brown colour.

This insect is a native of Mexico, and had been employed by the natives as a red tinging matter. When the Spaniards entered that country in 1518 it drew their attention; and in 1523 Cortes received orders from the court of Spain to procure it in as great quantity as possible. He left the cultivation of the insect to the natives, who prosecuted it so successfully that great quantities of it were imported into Europe. The earlier Spanish writers described it as an insect, but at a later period it came to be considered as the seed of a plant; and this opinion continued the prevalent one, till the contrary was proved by Melchior de Ruuscher, about the beginning of the eighteenth century. This man, who was a native of Holland, affirmed in a society, from oral information which he had obtained in Spain, that cochineal was a small animal. Another person, whose name has not been made known, maintained the contrary with so much heat and violence, that the dispute at length ended in a bet. Ruuscher charged a Spaniard, one of his friends, who was going to Mexico, to procure for him in that country authentic proofs of what he had asserted. These proofs, legally confirmed in October 1725, by the court of justice in the city of Antiguera, in the valley of Oaxaca, arrived at Amsterdam in the autumn of the year 1726. Ruuscher caused this evidence to be published under the following title: *The History of Cochineal proved by authentic documents*.[3]

The fact that cochineal is an insect had been suspected before. In a very crude and unsatisfactory paper on cochineal, published in the *Philosophical Transactions for* 1668,[4] this is distinctly stated as an undoubted fact. In 1672 Dr Lister, in a paper inserted also in the *Transactions*, throws out a conjecture that the cochineal insect may be a sort of kermes; which conjecture is now known to be well founded. Leeuwenhoeck is said to have examined cochineal microscopically in 1703, and to have ascertained it to be an insect. About the beginning of the year 1757 Mr Ellis obtained some of the joints of the plant on which the insects breed, from South Carolina, and presented them the same year to the Royal Society. These specimens, Mr Ellis observes, were full of the nests of this insect, in which it appeared in its various states, in the most minute, when it walks about, to the state when it becomes fixed, and wrapt up in a fine web which it spins about itself. With the assistance of the microscope, Mr Ellis discovered the true male insect in the parcels which had been sent to him from America; and in August 1756, in consequence of Mr Ellis's discovery, Dr Garden caught a male cochineal fly, which, he observes, is rarely to be met with. He supposes that there may be 150 or 200 females for one male. These discoveries proved indisputably that the cochineal is an animal production.

[4] No. xl. p. 796.

Contains cochinealin.

Cochineal has been subjected to a chemical examination by various individuals; but the most successful analysis of it is by Pelletier and Caventou in 1818, which was published in the eighth volume of the *Annales de Chimie et de Physique*, p. 250. They found it to contain about half its weight of the peculiar colouring matter to which they applied the name *carmine;* but we prefer the name cochinealin, already given to this substance by John, who was the person that first obtained it and described its properties. Cochinealin may be obtained by the following process:—

Digest cochineal in alcohol, as long as it communicates a red colour to that liquid. The alcoholic solution being left to spontaneous evaporation, lets fall a crystalline matter of a fine red colour. Dissolve these crystals in strong alcohol, and mix the solution with its own bulk of sulphuric ether. The liquid becomes muddy, and gradually deposites the cochinealin, which constitutes a purple crust on the bottom of the vessel.

Properties of cochinealin.

Cochinealin has a fine purple-red colour, is granular, and consists of small crystals. When left exposed to the air, it undergoes no sensible alteration. At 122 degrees it melts; and if the heat be increased, it swells up and is decomposed, yielding carburetted hydrogen gas, a great deal of oil, and a little water having a slightly acid taste. It furnishes no traces of ammonia.

It is very soluble in water. The aqueous solution has a fine carmine colour, and, how much soever concentrated, does not deposite crystals. It dissolves also in alcohol; but the solubility diminishes in proportion to the strength of the alcohol. In sulphuric ether it does not dissolve. The weak acids dissolve it, probably in consequence of the water which they contain. When the cochinealin is pure, no acid throws it down from its aqueous solution; but they precipitate it when in combination with the peculiar animal matter of cochineal. They produce a sensible change upon its colour, causing it gradually to assume a tint of yellow. This is the reason why cochineal will not dye scarlet, unless when mixed with bitartrate of potash. The concentrated acids decompose it altogether.

Alkalies also alter the colour of solutions of cochinealin. It first becomes violet, and at last yellow; and the original colour cannot be again restored. Lime-water occasions a precipitate when poured into an aqueous solution of this substance; but barytes and strontian water occasion no precipitate, though they change the colour to yellow. Alumina has a strong affinity for cochinealin. When newly precipitated alumina is agitated in an aqueous solution of it, the liquid is rendered colourless, and the alumina converted into a beautiful *lake.* The pigment called *carmine*, accidentally discovered by a Franciscan monk about the middle of the sixteenth century, and the process for obtaining which was published by Homberg in 1656, consists essentially of a combination of cochinealin and alumina.

Most of the saline solutions alter the colour of the aqueous solution of this substance; but few of them are capable of producing a precipitate in it. Acetate of lead, however, throws down a copious violet sediment from the decoction or infusion of cochineal; and by decomposing this sediment by means of sulphuretted hydrogen, the cochinealin may be obtained in a state of purity. The chloride of tin throws down a violet precipitate, and the perchloride strikes a fine scarlet colour, but precipitates nothing. When gelatinous alumina is added to this mixture, we obtain a fine red precipitate, which is not altered by boiling.

Cochineal was at one time used in great quantity in Europe, chiefly for dyeing fine scarlet cloth. When Bancroft published his work on colours in 1794, he informs us that the annual European consumption was about 3000 bags, or 600,000 lbs., of which about 240,000 lbs. were consumed in Great Britain. The demand has since that time very much diminished; and the price has in consequence sunk from about thirty shillings to about nine shillings and sixpence per pound. This diminution is chiefly owing to the substitution of the lac dye for cochineal. Cochineal, however, is still used for the dyeing of fine scarlet cloth.

3. *Kermes.*—This is also the female of an insect which inhabits a species of oak. The tree, which is a native of the countries bordering on the Mediterranean and Asia, is called by Linnæus *quercus ilicis*, and the insect *coccus ilicis.* This substance was known to the ancients, though they were ignorant of its nature. Dioscorides calls it κοκκος, and Pliny *coccum* and *granum.* It was used in medicine; and there can be no doubt that it was employed in Asia at a very early period as a dyestuff. There is reason to suspect that the *scarlet* cloth mentioned by Moses to adorn the tabernacle was dyed by means of kermes. If this conjecture has any foundation, the kermes dye must have been known in Egypt before the time of Moses.

The word *kermes* or *alkermes* is at present in the East the common name for the animal which produces the dye, as well as for the dye itself. Probably it comes from the Arabic. If the kermes dye was known in Egypt and Phœnicia in the time of Moses, there is some difficulty in explaining how it was altogether unknown to the Greeks and Romans till the time of the Emperor Aurelian, who began his short reign in the year 270 of the Christian era. Vopiscus informs us that the king of Persia sent to that emperor, besides other articles of great value, some woollen cloth, which was of a much costlier and brighter purple than any that had been ever seen in the Roman empire, and in comparison of which all the other purple worn by the emperor and the ladies of the court appeared dull and faded. Vopiscus goes on to say that this cloth had been dyed in India, and that the assertion of the king of Persia, *sume purpuram qualis apud nos est*, was false; for Aurelian, Probus, and Diocletian, had sent dyers into the East on purpose to get information respecting this precious dye; but that their attempts utterly failed of success.[1]

From this passage it would appear that the use of kermes in dyeing had been known at a very early period in India, from which it gradually made its way into Persia, and afterwards into Europe. And as the colour which it yielded was more beautiful than the celebrated Phœnician dye, it may have contributed to put an end to the monopoly of the Phœnician dyers. The term *scarlet*, the origin of which is unknown, but which was certainly employed early in the twelfth century, was applied to the colour given to cloth by the kermes dye.

---

[1] Vopiscus in *Vita Aureliani*, cap. 29.

Kermes is gathered chiefly in Languedoc, Spain, and Portugal. The insects are collected in the months of May and June, when the female, which alone is useful, is distended with eggs. To destroy the young insects, the kermes is exposed to the steam of vinegar for about half an hour, and afterwards dried. It is in the form of small grains of a reddish-brown colour. Kermes, as appears from the experiments of Lassaigne,[1] contains the very same colouring matter as cochineal; but its quantity is not so great, and of course it is mixed with a greater proportion of animal matter. The introduction of cochineal greatly diminished the consumption of kermes. It is seldom used in this country, yet it gives a very fixed and beautiful colour to woollen cloth.

4. *Lac.*—This is an animal production which has been long known in India, and used for dyeing silk and other purposes. It is the *nidus* of the *coccus lacca*, Linnæus, and is generally produced on the small branches of the *croton lacciferum*. Three kinds of lac are well known in commerce:—1. Stick lac is the substance or comb, in its natural state, forming a crust on the small branches or twigs. 2. Seed lac is said to be only the above separated from the twigs and reduced into small fragments. Mr Hatchett, who has examined this substance with his usual skill and precision, found the best specimens considerably deprived of their colouring matter.[2] According to the information which he received from Mr Wilkins, the silk dyers in Bengal produce the seed lac by pounding crude lac into small fragments, and extracting part of the colouring matter by boiling. 3. Shell lac is prepared from the cells, liquefied, strained, and formed into thin transparent laminæ. There is also a fourth kind, called *lump lac*, which is obtained from the seed lac by liquefaction, and afterwards formed into cakes. The best lac is of a deep red colour: when it is pale and pierced at the top, the value is greatly diminished; for then the insects have left their cells, and it can no longer be of use as a dyestuff.

Als imi- lar co- chin l.

Unverdorben has likewise examined lac, but his experiments throw no light upon the nature of the colouring matter. Being derived from a coccus, as well as the colouring matter of cochineal and kermes, the probability is that it is of the same nature. In the state in which it comes to this country (that of a purple powder), it dissolves readily in boiling hot water. In this way it is employed by the dyers. Being much cheaper than either cochineal or kermes, it has in some measure superseded these dyestuffs, except when a very fine scarlet is wanted, in which case cochineal is still employed.

5. *Archil.*—This substance, called *orseille* by the French, is a violet-red paste, of which there are two varieties, one, which is the best, made in the Canary Islands, the other manufactured in the south of France. It is made from two species of lichens, the roccella and the parellus. Berthollet, who has copied Hellot, who again copied Micheli, has given the following description of the mode of preparing it. The plant is reduced to a fine powder, which is afterwards passed through a sieve, and slightly moistened with stale urine. The mixture is daily stirred, each time adding a certain proportion of soda in powder, till it acquire a clove colour. It is then put into a wooden cask, and urine, lime-water, or a solution of sulphate of lime (*gypsum*), is added in sufficient quantity to cover the mixture. In this state it is kept; but to preserve it any length of time, it is necessary to moisten it occasionally with urine. We suspect that soda is not employed in the preparation of this dyestuff; at least it is not employed in the manufacture of cudbear, the preparation of which, being a manufacture of this country, we have often witnessed.

H pre- pa .

If we adopt the opinion of Tournefort, the preparation of archil was known to the ancient Greeks. He thinks that the purple of Amorgos, one of the Cyclades, the colour given to the famous tunics of that country, was formed by a dyestuff made from the lichen roccella.[3]

Cudbear how prepared.

What is called in this country *cudbear*, and in Germany *persio*, is prepared from the lichen *tartareus*, and *omphalodes*, by a process quite similar to that employed for making archil. The lichen is steeped and left for some time in flat vessels moistened with ammonia distilled from putrid urine. When the purple colour is sufficiently developed, the whole is dried in the open air, and reduced to a fine powder. The manufacture of this dyestuff was begun about the year 1777, at Leith, by Mr Mackintosh and Dr Cuthbert Gordon, from which last the British name of *cudbear* (originally *Cuthbert*) is derived. Leith was found an improper place for the manufacture; but Mr Mackintosh transferred it to Glasgow, and manufactured cudbear during the rest of his life with success. He left it to his son Charles Mackintosh, Esq. who still carries it on. The lichens used were at first collected in the Highlands of Scotland; but the rocks of that country being stript of their covering, the manufacturers had recourse to Sweden and Norway, and likewise to Sardinia, from which countries prodigious quantities of the lichens were brought. There is said also to be a manufactory of cudbear in Liverpool.

Neither archil nor cudbear are capable of giving fast colours to cloth; but they are considered as indispensable by the dyers, because they greatly improve the brilliancy of some of the colours.

Contains erythrin.

The nature of the substance in the lichen roccella, which furnishes the colouring matter of archil, has been investigated by Heeren, who has distinguished it by the name of *erythrin*. It may be obtained from the lichen by the following process: Digest the lichen for some time in alcohol, taking care not to raise the heat to the boiling point, because at that temperature a portion of the erythrin is decomposed. The alcoholic solution has a green colour. Filter it while hot, and mix it with twice its bulk of water, which will render it muddy. Raise the liquid to the boiling temperature, and introduce into it chalk in powder, until the precipitate, which was at first dispersed through the liquor, collects in flocks. This precipitate consists chiefly of *roccellate of lime*.[4] The liquid must be filtered while boiling hot. During the cooling it deposites erythrin in the state of a fine powder, of a brown colour. Dissolve it in hot alcohol, digest the solution with ivory black, filter, and mix it with one and a half times its bulk of boiling water. The liquor remains at first clear, but during the cooling the erythrin precipitates nearly white.

The following process for extracting erythrin from the lichen roccella is easier than the preceding. Pour on the lichen a small quantity of concentrated ammonia, and digest for some time, stirring well, but without the application of heat. Dilute the muddy and reddish solution thus obtained with water; and then add to it some dilute solution of chloride of calcium. Roccellate of lime precipitates, and the filtered liquid has a reddish colour. Add to it a slight excess of muriatic acid. The erythrin precipitates instantly, and gives the liquid the aspect of a yellowish jelly. When we heat to the boiling temperature, the erythrin is again dissolved, and it is precipitated in powder during the cooling of the liquid. It may be deprived of its brown colour by ivory black.

[4] Roccellic acid is an acid discovered by Heeren in the lichen roccella.

Its properties.

Erythrin is a soft powder, having usually a slight shade of red, and a slightly crystalline aspect, when obtained from a weakly acid liquid. When pure it is perfectly white. It has neither taste nor smell. At a temperature a little above 212°, it melts into a transparent liquid, which becomes hard and brittle during the cooling. If the heat be raised still higher, it froths, is partly volatilized, and partly charred; but not the least trace of ammonia can be observed to be formed. Hence we may conclude that erythrin contains no azote. When held to the flame of a candle it burns like a resin. It is scarcely soluble in cold water, and requires 170 times its weight of boiling water to dissolve it. At the temperature of 53° it dissolves in twenty-two and a half times its weight of alcohol, of specific gravity 0·825. It is soluble in 2·29 times its weight of the same alcohol at the point of ebullition. When this last solution cools, the whole is converted into a mass of the consistence of mortar. It is insoluble in ether, and little soluble in oil of turpentine. Muriatic acid has no action on it, but acetic acid dissolves it with facility when boiling hot, but lets it fall again on cooling. Both nitric acid and concentrated sulphuric acid dissolve it, but they alter its nature. The aqueous solutions of the alkalies, or their carbonates, dissolve it with facility, and the solutions are colourless. By the continued action of the alkalies, the erythrin is decomposed. When this action takes place in close vessels, an extractive substance is formed, which is soluble in water, having a bitter taste, and which Heeren on that account has called *bitter of erythrin.* When the action is continued in vessels to which the air has access, the red or rather violet substance is formed which constitutes the colouring matter of archil.

During the conversion of erythrin into the red matter three different substances are obtained, namely, the *red colouring* matter, a *yellow* substance, and a *wine-red* substance. They are first mixed or combined; but the red colouring matter may be separated by dissolving the compound substance in alcohol, evaporating the solution to dryness, and digesting the residue in ammonia. The red colouring matter remains when this solution is evaporated.

It is little soluble in water. Alcohol dissolves it, and the solution has a crimson-red colour. It is quite insoluble in ether. The alkalies and their carbonates dissolve it, and the solution has a fine deep colour. The acids throw it down from these solutions under the form of carmine red powder, but they do not precipitate it from its solution in alcohol. Heeren has shown that alcohol has the property of altering erythrin, and of converting it into a snow-white substance, to which he has given the name of *pseudo-erythrin,* because it does not yield the red colouring matter, but only the wine red. It has been analyzed by Liebig, who found its constituents,

Carbon	60·810
Hydrogen	6·334
Oxygen	32·856

These correspond with

8 atoms carbon	6
5 atoms hydrogen	0·675
3¼ atoms oxygen	3·25
	9·925

Hence these atoms, or some multiple of them, must represent the composition of pseudo-erythrin.

Colouring matter of cudbear.

The colouring matter of cudbear is obviously very nearly the same as that of archil. It has been slightly examined also by Heeren, who has pointed out some distinctive characters which it possesses.

In France, besides the lichen parellus, the lichen dealbatus is employed, and the archil is obtained by treating the lichens with putrid urine and lime. Robiquet has subjected the lichen dealbatus to a chemical analysis, and has extracted from it the matter which yields the red dye, and which he has distinguished by the name of *orcin.* It constitutes white crystals, having a sweetish and nauseous taste, melts when heated, and may be distilled over without decomposition. It dissolves both in water and alcohol. It is obvious that its properties are quite different from those of erythrin; yet the process for converting it into the red dyestuff is nearly the same as for archil and cudbear.

6. *Carthamus,* or *Safflower.*—This is the petals of the blossoms of the carthamus tinctorius, a plant formerly cultivated in Germany and France; but now the dyestuff comes usually from Egypt and the countries round the eastern part of the Mediterranean, and from India.

The method of preparing the flowers of carthamus in Egypt, as it is described by Hasselquist, is the following. After being pressed between two stones, to squeeze out the juice, they are washed several times with salt water, pressed between the hands, and spread out on mats in the open air to dry. In the day time they are covered, that they may not dry too fast with the heat of the sun, but they are left exposed to the dew of the night. When they are sufficiently dry, they are put up, and kept for sale under the name of *saffranon.* Care should be taken afterwards not to keep it in too dry a place; for unless it is a little moist, its properties are considerably impaired.

Carthamus contains two colouring substances, a yellow substance, which is soluble in water; and as it is of no use, it is extracted by the process mentioned above, by squeezing the flowers between stones till no more colour can be pressed out. The flowers become reddish in this operation, and lose nearly one half of their weight. The other colouring matter, which is red, is soluble in alkaline carbonates, and it is precipitated by means of an acid. A vegetable acid, as lemon juice, has been found to produce the finest colour. Next to this, sulphuric acid produces the best effect, provided too great a quantity, which would alter and destroy the colour, be not employed. The juice of the berries of the mountain-ash, or *rowan-tree* (*sorbus aucuparia,* Lin.), is recommended by Scheffer as a substitute for lemon juice, and it is thus prepared. The berries are bruised in a mortar with a wooden pestle, and the expressed juice, after it has been allowed to ferment, is bottled up. The clear part, which is most acid, becomes fitter for use the longer it is kept; but this operation requires a period of some months, and can only be conducted in summer.

From the colouring matter extracted by means of an alkali, and precipitated with an acid, is procured the substance called *rouge,* which is employed as a paint for the skin. The solution of carthamus is prepared with crystals of soda, and precipitated with lemon juice which has stood some days to settle. After being dried on delft plates with a gentle heat, the precipitate is separated, and ground accurately with talc which has been previously reduced to a very subtile powder; and on the fineness of the talc depends the difference between the cheaper and dearer kinds of *rouge.*

Carthamus furnishes about five per cent. of this matter (abstracting the talc), which is the true red colouring matter. It reddens vegetable blues while moist, whether from the acid employed in throwing it down, or from its own acid properties, has not been determined. It is insoluble in water and dilute acids, but slightly soluble in

Si ple Co rs.

alcohol. The solution has a rose-red colour, but when boiled becomes yellow. Ether is still a worse solvent of *rouge* than alcohol. It is insoluble in oils, both volatile and fixed; but it dissolves readily, and with a yellow colour, in alkaline leys, or alkaline carbonates. According to Dobereiner (who considers it as an acid, which he calls *carthamic*), soda saturated with it crystallizes in fine colourless needles, having a silky lustre, which become instantly red when an acid is added to them.

As a dyestuff, safflower affords only a fugitive colour, destroyed by exposure to the sun, and removed by washing. It is used, however, occasionally to give a red colour to silk.

7. *Brazil Wood.*—This wood comes from Brazil, and from Pernambuco; and in the former case is said to be the wood of the *cæsalpina sapan*, *cæsalpina crista*, and *cæsalpina vesica*; in the latter, of the *cæsalpina echinata*. These trees are large, and rich in colouring matter. The wood is very hard, and is said to sink in water. When fresh cut it is pale, but becomes reddish by exposure to the air. Its taste is sweetish. The red colouring matter of Brazil wood is very easily acted on by chemical agents, acids rendering it *yellow*, and alkalies *violet*. Chevreul has given us the following process for extracting this colouring matter in a state of purity. Digest the raspings of the wood in water till that liquid has dissolved all the colouring matter, and evaporate the infusion to dryness, to get rid of a little acetic acid which it contains. Dissolve the residue in water, and agitate the solution with litharge, to get rid of a little fixed acid which it contains. Evaporate again to dryness. Digest the residue in alcohol: filter and evaporate to drive off the alcohol. Dilute the residuum with water, and add to the liquid solution of gelatine, till all the tannin which it contains is precipitated. Filter again, evaporate to dryness, and digest the dry mass in alcohol, which will leave undissolved the excess of gelatine that may have been added. This last alcoholic solution being evaporated, the pure colouring matter of Brazil wood remains behind.

Co ring ma r how b- tai l.

It s oper- ti

It is soluble in water and in alcohol, but its fine red colour does not appear till all the acid which it naturally contains is saturated. Acids give it a yellow colour. The sulphuric, nitric, and muriatic acids, give it a pale dirty yellow. Fluoric acid gives it at first a yellow colour, which is gradually altered to grayish green; while the phosphoric and citric give it a fine permanent yellow colour, which might be employed for dyeing silk and wool. For these facts we are indebted to Bonsdorf. A very minute quantity of alkali gives the infusion of Brazil wood a violet colour; it is therefore a delicate re-agent for alkalies. When neutral salts, with an alkaline base, are dissolved in the infusion of Brazil wood, it assumes a rose-red colour. Acetates act most decidedly in producing this effect. When newly precipitated alumina is agitated in this infusion, it assumes a carmine-red colour.

When Brazil wood is boiled in water, we obtain a rose-coloured solution, and the undissolved wood becomes black, but still yields to alcohol a dark-red colour. When an acid is poured into the decoction, a red precipitate falls, and the filtered liquid is yellow. Ammonia gives the decoction a purple colour, and throws down a purple precipitate. The carbonates of potash and soda render it carmine red, and throw down a precipitate of the same colour. Alum throws down an abundant carmine precipitate, but the liquid retains the same colour. The protochloride of tin gives a rose-red precipitate, and renders the decoction colourless.

F s red in

Brazil wood is the substance from which red ink is prepared. The colour which it communicates to cloth has very little permanence; yet it is occasionally employed in dyeing cotton what are technically called *chemical colours*, by which is understood colours that will not resist washing. The decoction of Brazil wood, which is called juice of Brazil, is found to answer better for the process of dyeing when it has been kept some time, and has even undergone some degree of fermentation, than when it has been fresh prepared. The colour by keeping becomes of a yellowish red.

Simple Colours.

Within the last five or six years, Brazil wood has been nearly superseded by a wood imported from Africa, to which our dyers give the name of *camwood*. It is richer, and gives a finer colour, than any of the varieties of Brazil wood. It is not so much affected by alkalies, nor so liable to assume a violet shade; and the yellow colouring matter with which it is mixed gives the red a more lively appearance. We have not learned the botanical name of the tree which yields this wood.

8. *Logwood.*—This wood is usually, on the Continent, called *Campeachy wood.* It is the wood of the *hematoxylon Campeachianum*, a tree which grows to a considerable size in Jamaica, and on the eastern shore of the Bay of Campeachy. Its specific gravity is greater than that of water; it has a fine grain, and is susceptible of a fine polish. Besides the colouring matter to which it owes its value, logwood contains resin and oil, which are soluble in water; acetic acid and salts, consisting of potash and lime, combined with a vegetable acid, which are soluble in water saturated with chloride of potassium. It contains also sulphate of lime, oxalate of lime, a little alumina, and some peroxide of iron and oxide of manganese. Chevreul, to whom we are indebted for a chemical examination of logwood, has given the following process for extracting its colouring matter, which he has distinguished by the name of *hematin*.

Yields hematin.

How obtained.

The raspings of the wood are digested in water of a temperature from 122° to 131°, till every thing soluble is taken up. Evaporate the aqueous solution to dryness by a gentle heat, and treat the residue with alcohol of the specific gravity 0·843, which dissolves the colouring matter, leaving a brown residue still containing colouring matter in chemical combination. Filter the alcoholic solution, and distil it till what remains becomes of the consistence of a syrup. This syrup being mixed with some water, crystals begin immediately to be deposited. Leave it for twenty-four hours to evaporate spontaneously, then decant the liquid portion from off the crystals, and wash them with a little alcohol. The decanted liquid being left to spontaneous evaporation, will yield more crystals, and finally remains a thick uncrystallizable liquid. If it be evaporated to dryness, macerate the dry mass in cold water, and evaporate afresh: more crystals are obtained, which may be purified, like the other, by washing them in alcohol. These crystals thus obtained constitute *hematin*, or the pure colouring matter of logwood.

Its properties.

They have considerable lustre, and a scarlet colour. Under the microscope they appear to constitute needles arranged in sphericles. When rubbed on a glass it appears *orange* by transmitted light, and white by reflected light. But if we let fall on it a drop of alcohol, it appears *carmine red* by transmitted, and *yellow* by reflected light. When put into the mouth it is at first tasteless; but after some time a sensation of astringency, acridity, and bitterness, is perceived. When heated in a retort to decomposition, it gives out among other products ammonia, from which we may conclude that it contains azote. After every thing volatile is driven off, there remains fifty-four per cent. of charry matter half fused; which, when burned in the open air, leaves a quantity of lime and peroxide of iron, amounting to rather less than one per cent. of the hematin employed.

Hematin requires for solution 1000 times its weight of water. By evaporation it does not yield crystals, but when very much concentrated it is converted into a confused crystalline mass. It dissolves in alcohol and ether, and the solutions have a reddish-yellow colour. It combines with the acids, which render it yellow when added in small quantity; but when in a larger proportion they give it a red colour. Sulphurous acid and carbonic acid give the solution of hematin a pale-yellow colour. Boracic acid gives it a pale-red, and phosphoric and phosphorous acid a pale-orange colour. Arsenious acid has no sensible action on it. Sulphuretted hydrogen gas renders it yellow; and if we keep a solution of hematin charged with this gas for some time in a corked phial, it loses its colour altogether; but the colour appears if we remove the gas by means of a little oxide of lead. The salifiable bases give solution of hematin a violet, purple, or blue colour. With the fixed alkalies it forms compounds perfectly saturated and soluble. The alkaline earths fall down in combination, and have a purple colour when they fall from neutral salts, and a blue colour when from subsalts. An excess of alkali destroys the colour altogether. With the hydrated oxides of antimony, zinc, bismuth, nickel, iron, and copper, it forms blue or purple coloured compounds. The compound which hematin forms with alumina and oxide of copper at once may be fixed upon linen or cotton, and gives a blue colour like that of indigo, only it is rendered yellow by the concentrated acids, while indigo remains unchanged, unless the acid be the nitric. The protoxide of tin, when united with hematin, forms a blue-coloured compound, while its combination with the peroxide of tin is red. We see from this that the protoxide of tin possesses the characters of an alkali, while the peroxide is an acid. A solution of gelatine throws down a concentrated solution of hematin purple.

Hematin is easily altered. When a mixture of alkali and hematin is kept *in vacuo*, or in a well-corked phial, quite full, no action takes place; but when air has access, oxygen is absorbed, and the hematin quite destroyed in a few hours. During this action, the blue colour of the liquid changes first into red, and then into brown. The alkali becomes saturated with carbonic acid.

II.—*Method of dyeing Wool Red.*

All the colouring matters employed for dyeing wool red by modern dyers require a mordant to fix them. The shade of colour depends partly upon the kind of colouring matter used, partly on the mordant, and partly on the quantity of colour which the cloth is made to imbibe by the length of time that it remains exposed to the action of the dyeing liquor. The purple of the ancients, the colouring matter of which was obtained from different species of shell-fish, required no mordant; but it has already been observed that this mode of dyeing has been for ages out of use.

Madder red.

Madder Red.—Madder is only employed for dyeing coarse woollen stuffs; and the following is the process. The stuffs are first boiled for two or three hours with alum and tartar; they are then left to drain, slightly wrung out, put into a linen bag, and carried into a cool place, where they are to remain for some days. The quantities and proportions of the alum and tartar are varied according to the views of the dyer, and the shade of colour which is wanted. Some recommend five ounces of alum and one ounce of tartar to each pound of wool. By increasing the proportion of tartar to a certain degree, a deep and permanent cinnamon colour, instead of a red, is produced. This arises from the yellow tinge which is induced by means of the acid on the colouring particles of the madder. Others propose to diminish the proportion of tartar, and to employ only a seventh part. In conducting the process of dyeing with madder, the bath should not be brought to the boiling point; because at that temperature the fawn-coloured particles would be dissolved, and a different shade obtained from that which is desired. When the water is at that degree of temperature which the hand can bear, Hellot recommends the addition of half a pound of grape madder for every pound of wool to be dyed. It is then to be well stirred before the wool is introduced, which must remain for an hour without boiling, excepting for a few minutes towards the end of the process, that the combination of the colouring particles with the stuff may be more certain.

Proce

Rosir

Madder reds are sometimes rosed, as it is called, with archil and Brazil wood. In this way they become more beautiful and velvety; but this brightness is not permanent. But madder reds, even when they are most perfect, are far inferior to those obtained from lac and cochineal, and even to that produced by kermes; but as the expense of the materials is comparatively small, they are employed, as we have already observed, for coarse stuffs.

Propo of ma

Different authors recommend different proportions of madder. Poerner proposes to employ one third of the weight of the wool, while Scheffer limits the quantity to one fourth. In one process, Poerner added to the alum and tartar a quantity of solution of tin equal in weight to the tartar, and after two hours boiling allowed the cloth to remain in the bath, which had been left to cool for three or four days. He then dyed it in the usual way, and thus obtained a fine red. According to another process, he prepared the cloth by the common boiling, and dyed it in a bath slightly heated, with a larger proportion of madder, tartar, and solution of tin. The cloth remained twenty-four hours in the bath; and when it had become cold he put it into another bath, made with madder only, where it remained for twenty-four hours. By this process he got a fine red, somewhat brighter than the common, but inclining a little to yellow. Scheffer informs us that he obtained an orange-red by boiling wool with a solution of tin and one fourth of alum, and then by dyeing with one fourth of madder. A cherry colour is obtained, according to Bergman, by dyeing with one part of a solution of tin and two of madder, without previously boiling the wool. By exposure to the air this colour becomes deeper. By boiling the wool for two hours with one fourth of sulphate of iron, then washing it, and afterwards immersing it in cold water with one fourth of madder, and then boiling for an hour, the result is a coffee colour. But if the wool has not been soaked, and if it be dyed with one part of sulphate of iron and two of madder, the colour is a brown approaching to red.

Diffe t mord s.

When sulphate of copper is employed as the mordant, the madder dye yields a clear brown, inclining somewhat to yellow; and a similar colour may be produced by dyeing the wool, simply soaked in hot water, with one part of sulphate of copper and two of madder. But when this mordant and dyestuff are used in equal proportions, the yellow is somewhat more obscure, approaching to green; and in both these instances exposure to the air does not produce a darker colour. Berthollet informs us that he employed a solution of tin in various ways, both in the preparation and the application of the madder; and by the use of different solutions of tin, he found, that although the tint was somewhat brighter than what is obtained by the common process, it was always more inclined to yellow or fawn colour.

Scarl

Scarlet.—The finest and most splendid of all colours is scarlet. This, like other colours, is of various shades, according to the quality and proportion of the colouring matter employed. The scarlet dye is communicated to woollen stuffs by means of cochineal, the history and properties of which we have already detailed. The Mexicans, as appears from their history, employed alumina as the basis or mordant to fix the colour of cochineal; and previous to the discovery of the solution of tin, the use of the same substance seems to have prevailed in Europe. The fine colour obtained from the latter received, as we have already mentioned, different names in different places; as that of *bow dye* in England, *scarlet of the Gobelins* in France, and in Holland *Dutch scarlet.*

Process.

Boiling.

In the process for dyeing scarlet two operations are necessary. The first is denominated the boiling, and the second is distinguished by the name of finishing or reddening. The operation of boiling, which is the first part of the process, is conducted in the following manner:—For one hundred pounds of cloth, six pounds of pure tartar are added to the water, which is made pretty warm. The bath is then to be briskly stirred; and when the heat has increased a little more, half a pound of powdered cochineal is to be added, and the whole is then to be well mixed. The next moment five pounds of a very clear solution of tin are to be poured in and carefully mixed. When the bath begins to boil, the cloth is introduced, and briskly moved for two or three turns: after which it is moved more slowly. The boiling having continued for two hours, the cloth is taken out, exposed to the air, and carried to the river to be well washed.

Reddening.

In the preparation of the second bath, which is for the reddening, the boiler is to be emptied, and when the bath has just reached the boiling point, five pounds and three quarters of cochineal, previously powdered and sifted, are to be added. These are to be carefully mixed; and after having ceased stirring, when a crust has formed on the surface, and opened of itself in several places, thirteen or fourteen pounds of solution of tin are poured in. Should the bath during the boiling rise above the edge of the boiler, it may be cooled with a little cold water. This solution being well mixed, the cloth is put in, and two or three times quickly turned. It is then boiled in the bath for an hour, taking care to keep it under the surface. It is afterwards taken out, exposed to the air, and, when it has cooled, washed in the river and dried.

Proportion of ingredients.

There are no determinate proportions of cochineal and solution of tin in either of these operations. Hellot informs us that some dyers employ two thirds of solution of tin and one fourth of cochineal in the boiling or first operation, and the other one third of the solution of tin with the remaining three fourths of the cochineal in the second operation, or the reddening. He adds farther, that the use of tartar gives a greater degree of permanency to the colour, provided the proportion do not exceed one half the weight of the cochineal employed. According to Berthollet, several dyers at present adopt this practice. Tartar, he observes, promotes the solution of the colouring matter; and this effect is greater when it is ground with the cochineal, after which it is found that the residuum is more completely exhausted. But this consideration is of inferior consequence when the operations are successively performed, because any colouring matter that may remain in the residuum is employed in the next operation. It ought not, however, to be overlooked, that the tartar communicates to the colour a rosy hue.

Shorter process.

It is the practice of some dyers not to remove the cloth out of the boiling. They merely refresh it, and perform the operation of reddening in the same bath. When this is done, the infusion of cochineal, made in a separate vessel, and mixed with the proper proportion of solution of tin, is added. By conducting the process in this way the scarlet is supposed to be equally fine, and there is a considerable saving of time and fuel.

Brighter red.

To give scarlet the bright lively red, which, as it approaches to the colour of fire, has been distinguished by the name of *fiery scarlet*, a yellow tinge is communicated by boiling fustic in the first bath, or by adding a little turmeric to the cochineal. A larger proportion of the solution of tin also produces this yellow shade, but it renders the cloth harsh, and limits the action of the colouring matter. The use of fustic or turmeric, therefore, although the colour obtained from them is not permanent, is preferable to an excess of the solution of tin. When these substances are used, the inside of the cloth, when it is cut, appears yellow; but in the ordinary processes, the cochineal, it is found, does not penetrate the cloth, for when no other substance is employed the cloth is internally white.

Tin and copper boilers.

The use of tin boilers is recommended in dyeing scarlet. When copper boilers are employed, the acid acts on the metal, and thus forming a solution, injures the beauty of the colour. Tin boilers, however, are attended with several inconveniences. It is difficult to procure them of sufficient size, and they are apt to be melted by the incautious continuance of the fire after they have been emptied. In the use of copper boilers there are several necessary precautions. They must be kept very clean, the acid liquor should not be allowed to remain in them for any length of time, and some contrivance should be adopted to prevent the cloth from touching the metal, either by using a net or a wicker basket.

Different proportions of ingredients.

Different proportions of materials, we have observed, are recommended by different authors. For the boiling, Scheffer directs an ounce and a half of solution of tin, with an equal quantity of starch, and as much tartar, to every pound of cloth. The effect of the starch is to give more uniformity to the colour. When the water boils, a dram of cochineal is to be added; it is then to be well stirred, and after the wool is introduced, to be boiled for an hour, taken out, and washed. The proportions for the reddening bath, in which the wool is to be boiled half an hour, are half an ounce of starch, three fourths of an ounce of solution of tin, half an ounce of tartar, and seven drachms of cochineal. In Scheffer's process, it may be observed, the proportion of solution of tin is smaller than in that of Hellot, but the quantity of tin in the solution of the former is greater than in that of the latter.

Poerner's process.

Poerner has described three principal processes, according to the variety of the shade of the scarlet. He uses no cochineal in the boiling; the materials of which are one ounce and six drachms of tartar, and an equal weight of solution of tin, the latter being added after the tartar is dissolved, for every pound of cloth. As soon as the boiling has commenced, the cloth is introduced, and it is boiled for two hours. For the reddening of the first process he employs two drachms of tartar and one ounce of cochineal, adding gradually afterwards two ounces of solution of tin. For the reddening of the second process the same quantity of cochineal and solution of tin, without any tartar, is employed. In the reddening of the third process, two drachms of tartar with one ounce of solution of tin, one ounce of cochineal, and two ounces of common salt, are directed to be used. The colour produced in the first process has the deepest shade, that of the second is more lively, while that of the third is paler and brighter.

Different shades.

By the use of tartar in the reddening in different proportions, various shades of scarlet may be obtained. When it is employed, the shade is deeper and fuller; but when it is entirely omitted, the scarlet approaches to an orange colour. The shade of colour also is subject to considerable variety, from the different degrees of strength of the solution of tin. To ascertain this effect, Berthollet made a number of experiments. He found that a solution of tin, composed of sixteen parts of nitric acid, two of muriate of ammonia, and three of tin, produced a deeper shade than when the proportions of the acid and muriate of ammonia were equal, with only two parts of tin. The last proportions, he observes, succeeded best. Four parts of water were mixed with the solution. When the proportion of muriate of ammonia amounted only to half a part, the colour was brighter, and inclining to orange.

Use of common salt.

Common salt has the effect of increasing the brightness of scarlet, while it is also attended with the advantage of causing the colour to penetrate deeper into the cloth. It seems difficult to explain why common salt, which gives a deeper shade to the colour of the infusion of cochineal, and indeed produces a similar effect on colours in general, should diminish the intensity of the colour of scarlet. The proportion of common salt mentioned above is, according to Poerner, the greatest that can be employed. When less is used, the shade, though lighter, is more agreeable. By adding five ounces of white sugar to the ingredients of the second process, a fine colour, which is always lighter than that of the first process, will be obtained. The colour, it is said, is more permanent, and the shade more agreeable, when the cloth is left twenty-four hours in the boiler after it has cooled.

Method of using the lac dye.

For dyeing fine woollen cloth the lac dye is commonly used. It comes to the dyer in the state of a fine powder, having a brownish-red colour, inclining to violet. It contains much less colouring matter than cochineal, but is incomparably cheaper. To dye forty-three pounds of fine woollen cloth, six pounds of lac, three pounds of cream of tartar, and five pounds of tin mordant are put into a dyeing vessel, either of tin, or at least lined with tin, with a sufficient quantity of water. The whole is brought to the boiling temperature, and after it has boiled briskly a sufficient time to dissolve the colouring matter, the cloth is passed through it for about an hour, or till it has acquired the requisite depth of colour.

Tin mordant, how made.

The tin mordant used is made by dissolving two ounces of tin in thirty pounds of aquafortis mixed with one pound of muriatic acid. The solution is transparent, and it is kept in well-corked bottles for use. The tin is doubtless in the state of protochloride, though it sometimes also gets into the state of perchloride. Either state will answer, but in the second case the dyeing process is much slower, the cloth not seeming to imbibe the perchloride of tin so rapidly as the protochloride. From the above proportions, it is obvious that to dye forty-three pounds of woollen cloth scarlet, one third of an ounce of tin converted into protochloride is sufficient. This is rather less than 146 grains of tin; so that each pound of the woollen cloth combines with not more than 3·4 grains of tin. It is obvious from this that the particles of tin must be exceedingly minute indeed, otherwise 3·4 grains of tin could not be so minutely divided as to cover the surface of a pound weight of woollen cloth.

When the dyer wishes the scarlet to assume a brighter shade, he sometimes adds a little quercitron bark, which, by the yellow colour which it induces, adds materially to the brightness of the colour. This plan was first suggested by Dr Bancroft, and it has been since pretty generally acted on.

Dr Bancroft recommended the tin mordant to be prepared by dissolving tin in muriatic acid mixed with one fourth of its weight of sulphuric acid. This solution, he says, answers very well, and is much cheaper. We cannot find, however, that any of the dyers in this country follow that process. We can hardly think that the present method of using so much nitric and so little muriatic acid is a good one. The object being to obtain a protochloride of tin, one would think that muriatic acid would be a better vehicle. Tin dissolves in this acid very well, and the protochloride of tin formed in this way is easily obtained in crystals. But the tin mordant, as prepared by the dyers, contains a great excess of nitric acid; and we cannot avoid suspecting that this excess is connected with the shade of scarlet produced. The nitric acid doubtless renders a part of the colouring matter of the lac yellow, and thus changes the dark crimson colour natural to this dyestuff into scarlet.

Cochineal is still employed to a considerable extent in dyeing the finest kinds of woollen cloth scarlet. The process is precisely the same as when lac is employed, remembering only that cochineal is much richer in colouring matter than lac, and that therefore a smaller quantity will serve. Dr Bancroft introduced the method of putting the cochineal, the tin mordant, and the tartar into the dyeing vessel at once, and dissolving them all together in water before the cloth is passed through the liquid; and this method is pretty generally though not universally followed.

Dr Bancroft's method of using quercitron bark to supply the place of a portion of the cochineal, is likewise pretty generally followed. The price of cochineal, in consequence of the introduction of the lac dye, has sunk from thirty shillings the pound to about nine shillings and sixpence. This makes the saving not so considerable in point of expense as it was when Bancroft wrote, though even at present it is an important saving.

Diffe
shade
scarle

To produce different shades of scarlet, and the other colours which are derived from it, all that is necessary is to vary the proportions of cochineal, tartar, and solution of tin; and for the shades which incline most to yellow, the addition of quercitron bark or fustic is requisite. The use of the tartar is to deepen the colour, and the solution of tin produces a shade of orange. When the shade of colour required to be communicated to the stuff is light, the time of continuing the process must be shortened.[1]

Crim
dyed
one p
cess,

Crimson.—The processes which are employed to dye wool a crimson colour are two. The stuff is either dyed crimson at once, or the crimson shade is communicated to it after being previously dyed of a scarlet colour. To dye crimson by a single process, a solution of two ounces and a half of alum and an ounce and a half of tartar for every pound of stuff, is employed for the boiling, and the stuff is afterwards to be dyed with an ounce of cochineal. It is usual also to employ solution of tin, but in smaller proportion than for dyeing scarlet. The processes employed, it is scarcely necessary to observe, must vary according as the shade wanted is deeper or lighter, or more or less distant from scarlet. Common salt is also employed by some in the boiling. To render the crimson deeper, and to give it more bloom, archil and potash are frequently used; but this bloom, it ought to be observed, is extremely fugacious. By adding tartar and alum, the boiling for crimson is sometimes prepared after a scarlet reddening; and it is said that the colour possesses more bloom when both the boiling and reddening are made after scarlet, than when the crimson is dyed in a fresh bath prepared on purpose. In dyeing these colours the wild cochineal may be employed; but as it contains a smaller proportion of colouring matter, the quantity must be greater.

or by
conve
of sca

Different substances, as the alkalies, alum, and earthy salts in general, convert the colour of scarlet to crimson, which is the natural colour of cochineal. To effect this, the stuff previously dyed scarlet is boiled for an hour in a

---

[1] Berthollet, ii. 194.

Siple Cours.

solution of alum, the strength of which is to be regulated by the depth of shade required. In conducting this process, it is necessary to observe, that water impregnated with earthy salts has a considerable effect in varying the shade, so that the quantity of alum employed must be proportioned to the purity of the water. Hellot tried soap, soda, potash, and some other substances, and although they produced the crimson, yet it was of a deeper shade, and had less lustre, than what was produced by means of alum. Ammonia produced a good effect, but, from its great volatility, a considerable proportion must be put into the bath, moderately heated, with a little sal ammoniac, and an equal quantity of potash. By this process the stuff became of a bright rosy colour, and thus rendered a smaller quantity of cochineal necessary. Poerner directs the stuff, previously dyed scarlet, to remain twenty-four hours in a cold solution of sal ammoniac and potash.

Hagrain crimon, &c.

To produce crimsons, as well as scarlets, in half grain, madder is to be substituted for half the quantity of the cochineal; or in other proportions, according to the shade desired. The same boiling is given as for scarlet in grain, and the other parts of the process are to be conducted as for reddening the scarlet or crimson. Even the common madder red assumes a greater degree of lustre when the boiling is made after the reddening for scarlet.

At present we are not aware that kermes is ever employed by the dyers in this country. The use of this dye-stuff seems to have been completely superseded by cochineal and lac dyes. Certainly the colour given by kermes is not so fine as that given by these substances, but it has the advantage of being exceedingly durable.

III.—*Method of dyeing Silk Red.*

Dient prosses wit mad- der

Madder Red.—The colour which is obtained from madder does not possess sufficient brightness for dyeing silk. We shall here, however, describe some of the processes which are employed for this purpose. That of De la Folie is the following: Half a pound of alum is to be dissolved in each quart of hot water, and two ounces of potash are afterwards to be added. When the effervescence has ceased, and the liquor has become clear, the silk must be kept in it for two hours, after which it is to be washed and put into the madder-bath. The silk which is dyed in this way becomes more beautiful by means of the soap proof. The process of Scheffer is somewhat different. For each pound of scoured silk he directs a solution of four ounces of alum and six drachms of chalk to be prepared. When the sediment has formed, the solution is to be decanted, and having become quite cold, the silk is immersed in it, and left for eighteen hours. It is then taken out and dried, and afterwards dyed with an equal weight of madder. The colour thus obtained is of a dark shade. Mr Guhliche describes another process. For every pound of silk he proposes a bath of four ounces of alum and one ounce of solution of tin. When the liquor has become clear it is decanted, and the silk carefully soaked in it for twelve hours, after which it is to be immersed in a bath with half a pound of madder softened by boiling with an infusion of galls in white wine. The bath is to be kept moderately hot for an hour, and then made to boil for two minutes. The silk, being taken from the bath, is to be washed in a stream of water, and dried in the sun. The colour thus obtained is very permanent. By leaving out the galls it is clearer. The brightness of the first colour may be considerably increased by passing the stuff through a bath of Brazil wood, to which one ounce of solution of tin is added. In this way the colour becomes extremely beautiful and durable.

Pros with ra- zil od.

Silk is sometimes dyed with Brazil wood, and the colour thus obtained has been distinguished by the name of *false crimson*, to distinguish it from the more durable colour which is produced by cochineal. The silk, after being boiled with soap, is to be alumed. It is then to be refreshed at the river, and dipped in a bath more or less charged with Brazil juice, according to the depth of shade required. If pure water be employed, the colour will be too red for crimson; but to remedy this, the stuff may be passed through a weak alkaline solution, or a little alkali may be added to the bath, or the stuff may be washed in hard water till it has acquired the proper shade. To deepen the shade of false crimsons or dark reds, the solution of logwood is added to the Brazil bath, the silk being previously impregnated with the latter; or a little alkali may be added, according to the shade required.

Simple Colours.

With cochineal.

The crimson produced by cochineal is called *grain crimson*, to distinguish it from false crimson. The silk, being well cleansed from the soap at the river, is to be immersed in alum liquor of the full strength, and to remain for a night. It is then to be washed and twice beetled at the river. The bath is prepared by filling a long boiler two thirds with water, to which are added, when it boils, from half an ounce to two ounces of powdered white galls for every pound of silk. When it has boiled for a few moments, from two to three ounces of cochineal, also powdered and sifted, for every pound of silk, are put in, and afterwards one ounce of tartar to every pound of cochineal. When the tartar is dissolved, one ounce of solution of tin is added for every ounce of tartar. In the preparation of this solution of tin, the following proportions are recommended by Macquer. For every pound of nitric acid two ounces of sal ammoniac, six ounces of fine grain tin, and twelve ounces of water, are employed. When these ingredients are mixed together, the boiler is to be filled up with cold water; and the proportion of the bath for every pound of silk is about eight or ten quarts of water. In this the silk is immediately immersed and turned on the winch till it appear to be of a uniform colour. The fire is then increased, and the bath is kept boiling for two hours, taking care to turn the silk occasionally. The fire is afterwards put out, and the silk put into the bath, where it is allowed to remain for a few hours longer. It is then taken out, washed at the river, twice beetled, wrung, and dried. Two processes are recommended by Scheffer and Macquer. In that of the former, a greater proportion of cochineal is employed in the dye-bath; but in that of the latter, a yellow ground is previously communicated to the silk. The colour which is thus obtained resists the action of soap, and is more durable than that which is produced by means of carthamus.

Poppy red.

To obtain other shades of red, the above processes must be varied. If, after the silk has been wrung out of the solution of tin, it is steeped for a night in a cold solution of alum, in the proportion of one ounce to a quart of water, wrung, and dried, then washed and boiled with cochineal, it will only appear of a pale poppy colour; but a fine poppy red may be produced by steeping it twelve hours in the solution of tin, diluted with eight parts of water, then left all night in the solution of alum, washed, dried, and passed through the two baths of cochineal, taking care to add to the second bath a small quantity of sulphuric acid. The same colour may be produced by dyeing the silk previously with anotta, and then passing it successively through a number of baths prepared with an alkaline solution of carthamus, to which lemon juice has been added, till it acquire a fine cherry-colour. To brighten the colour, the silk, after being dyed, may be immersed in hot water acidulated with lemon juice.

Cherry red, &c.

Other shades of red, as a cherry red, and flesh red, are also produced by carthamus. For a cherry red it is not necessary that the stuff be previously dyed with anotta, and the proportion of colouring matter is smaller. A flesh-red colour is obtained by adding a little soap to the bath, which has the effect of softening the colour, and of retarding the action of the colouring matter on the stuff. To produce dark shades, it is sometimes usual to mix archil, and by this means the expense is diminished.

Scarlet.

Those who have produced a colour on silk which comes nearest to scarlet, Berthollet observes, begin with dyeing the silk crimson. It is then dyed with carthamus, and lastly it is dyed yellow without heat. By this process a fine colour is obtained; but the dye of the carthamus is not permanent, as it is destroyed by the action of the air, and the colour becomes deeper. The following is Dr Bancroft's process. In a solution of murio-sulphate of tin, diluted with five times its weight of water, the silk is to be soaked for two hours; and after being taken out, it is to be wrung and partially dried. It is then to be dyed in a bath prepared with four parts of cochineal and three of quercitron bark. In this way a colour approaching to scarlet is obtained. To give the colour more body, the immersion may be repeated both in the solution of tin and in the dyeing bath; and the brightness of the scarlet is increased by means of the addition of carthamus. A lively rose colour is produced by omitting the quercitron bark, and dyeing the silk with cochineal only; and by adding a large proportion of water to the cochineal, a yellow shade is obtained, which changes the cochineal to the compound scarlet colour.[1]

Rose colour.

IV.—*Method of dyeing Cotton and Linen Red.*

The dyestuff usually employed to give a red colour to cotton and linen is madder. It is easier to dye cotton than linen; but as the processes are the same for each, one general description will apply to both. There are two kinds of madder red; the one is called *simple* madder red, and the other, which was originally invented in the Levant, is distinguished in this country by the name of *Turkey red.* This last constitutes by far the brightest and most beautiful and permanent red which is communicated to cotton; we shall therefore proceed to give a somewhat particular account of the process.

The method was first put in practice in Glasgow about forty years ago, by M. Papillon, a French gentleman, who established a Turkey-red dye-work along with Mr Mackintosh. He made an agreement with the commissioners and trustees for manufactures in Scotland, that the process was to be by them published for the benefit of the public at the end of a certain term of years. The period agreed upon having expired in 1803, the trustees laid a minute account of the different processes before the public. Since that period Turkey-red dyeing has been conducted in Glasgow upon a very extensive scale. Different individuals, possessed of both chemical skill and considerable sagacity, have studied the different parts of this very complicated method of dyeing. The effects of each individual operation have been carefully investigated, and the whole has been somewhat shortened and simplified, though it still constitutes the most complicated process in the whole art of dyeing. The Turkey-red dye is practised by a considerable number of persons in Glasgow; but the oldest, and perhaps the most extensive establishment, is that of Henry Monteath and Company at Rutherglen Bridge. The character of that house has been long established, and the beauty of their Turkey-red dye is known and appreciated in every part of the globe where British manufactures are known. From Glasgow the Turkey-red dye has gradually made its way into Lancashire.

Cotton cloth which is to receive the Turkey-red dye is never bleached beforehand; because it has been found that the first parts of the processes succeed better with unbleached than with bleached cloth.

The steep

1. The first step of the dyer is to remove the weaver's dressing. This is done by steeping the cloth in a weak alkaline ley. To this the technical name of the *rot steep* is given. From four to five pounds of caustic potash are generally employed for every 100 lbs. of cotton cloth. The temperature of the solution is from 100° to 120°, and the cloth is kept in the steep for twenty-four hours, and then well washed.[2]

2. From seven to ten pounds of carbonate of soda are dissolved in a sufficient quantity of water to keep the cloth (supposed always to weigh 100 lbs.) wet. In this ley the cloth, previously deprived of the weaver's dressing, is boiled for some time.

The steep

3. The process which we are now going to describe is the one upon which the goodness of the Turkey-red dye depends more than upon any of the others. Without it the dye cannot be produced upon new cloth; but when cloth which has been frequently washed with soap is to be dyed (an old cotton shirt, for example), this process may be omitted altogether. It is evident from this that soap communicates to cotton cloth the same properties as the process which we are now going to describe.

A liquor is composed of the following ingredients:

1 gallon of gallipoli oil,
1½ gallon of soft sheep dung,
4 gallons of solution of carbonate of soda, of the specific gravity 1·06,
1 gallon of solution of pearl ash, of the specific gravity 1·04,

mixed with a sufficient quantity of cold water to make up twenty-two gallons. The specific gravity of this liquor should be from 1·020 to 1·025.

This liquor has a milk-white appearance, and is in fact a kind of incipient soap. It is put into a large wooden open cylindrical vessel, called the *liquor tub* (see Plate CCVI. fig. 1 and 2), and is kept continually in a state of agitation by a kind of wooden levers, driven round in it by machinery put in motion by the steam-engine. This liquor is conveyed by a tin pipe to the *padding machine*, which is situated in an apartment below. Several sections of this machine are given in the same plate, fig. 3, 4, and 5. A kind of trough in this machine is kept always full of the milky liquor, and the pieces of cloth to be dyed are made to pass through this liquid, and are thoroughly soaked with it.

By this process the cloth is impregnated with the soapy matter, and the longer this matter is left undisturbed on the cloth, the better does it take the dye. Fourteen days is the least period that this impregnation is allowed to remain.

The sheep dung gives the cloth a dark-green colour, and is found materially to assist the bleaching which the cloth afterwards undergoes. This bleaching goes on much more rapidly with than without the sheep dung, especially when the cloth is exposed on the grass between the different operations. In what way the sheep dung contributes to this acceleration has not been determined, but the fact is certain.[3]

4. When the weather is favourable, the cloth, after be-

---

[1] *Philosophy of Permanent Colours*, 312.

[2] In general the alkaline ley of No. 9 is worked up in this process, and when this is done less potash is required.

[3] No advantage has been found to result from using the alkalies caustic in this process; and a mixture of potash and soda answers much better than soda alone.

ing impregnated with the oleaginous liquor, is spread upon the grass to dry. But should the weather be rainy, as it would not do to allow the oleaginous liquid to be washed out by the rain, the goods are dried in the stove.

5. After the cloth has been dried in the stove, it is a second time impregnated with the oleaginous liquid described in No. 3, by means of the padding machine. It is then spread on the grass for some hours if the weather be favourable, and ultimately dried in the stove.

The impregnation with the oleaginous liquor, the exposure on the grass, and the stove drying, are repeated a third time. When the weather is rainy, which prevents exposure on the grass, and obliges the workmen to dry the cloth at once in the stove, the impregnation with the oleaginous liquor is sometimes repeated a fourth time.

Upon the sides of the tubs in which the oleaginous liquor is kept, a white solid crust gradually accumulates. This matter being examined, was found to consist almost entirely of phosphate of lime. It was doubtless derived from the sheep dung with which the saponaceous liquid was mixed.

6. The next process is to steep the cloth in a weak solution of pearl ash, of the specific gravity 1·0075 to 1·01, heated to the temperature of 120°. From this liquor it is wrung out and again dried.

7. A mixture is now made of the following substances:

1 gallon gallipoli oil,
3 gallons soda ley of specific gravity 1·06,
1 gallon caustic potash ley of specific gravity 1·04,

diluted with as much water as will make up the whole to twenty-two gallons. In this liquid, which is milky, like the preceding, and which contains an imperfect soap, the cloth used formerly to be tramped with the hand, and then wrung out. It is now soaked with the liquid by means of the padding machine, in the manner described under No. 3.

If the weather be fine, the cloth thus impregnated with the soap is exposed on the grass. It is then dried in the stove.

8. The above process (No. 7) is repeated thrice; and after each soaking in the saponaceous liquor, the cloth is exposed on the grass for some hours, and then dried in the stove.

9. The cloth, thus so many times soaked in the saponaceous liquor, is now steeped in a mixed ley of pearl ash and soda of the specific gravity from 1·01 to 1·0125, heated to the temperature of 120°. After being taken out of the steep, and allowed to drain for a few hours (taking care to preserve the liquor), the cloth is well washed. The object of this process is to remove any superfluous oil with which the cloth may be impregnated, the object being that all the oil adhering to the cloth should be in combination with an alkali. About half the alkali used in this process disappears during the steeping. The remaining liquor, which is about half as strong as at first, is reserved for future use. The cloth thus washed clean is dried in the stove.

T gall- in

10. The preceding washing is necessary for the success of the next operation, called the *galling;* for the nutgall liquor will not be imbibed by the cloth unless it be thoroughly freed from all uncombined oil, which would give it a greasy feel. If the first steeping in alkali and washing has not fully accomplished this necessary object, they ought to be repeated.

For the galling, eighteen pounds of Aleppo galls are to be boiled for four or five hours in twenty-five gallons of water till it is reduced to about twenty gallons; and the liquid being now passed through a sieve, is sufficient for impregnating 100 lbs. of cloth with the requisite quantity of nutgalls. Of late years, sumach from Sicily has been substituted for nutgalls, thirty-three lbs. of sumach being considered as equivalent to eighteen lbs. of nutgalls. Sometimes a mixture of nine lbs. nutgalls and sixteen and a half lbs. of sumach is employed.

Through this decoction the cloth is either tramped by the hand, or it is passed and soaked in it by means of the padding machine. The temperature of the decoction should be from 80° to 100°. It is unnecessary to steep the cloth in the gall liquor; a complete soaking is all that is necessary. The cloth, thus soaked in a decoction of fustic, comes out dyed yellow, a colour which serves to improve the madder red by rendering it more lively.

The aluming.

11. The next process is to fix the alumina mordant upon the cloth. This step is essential, because without it the madder dye would not remain fixed in the cloth, but would be easily washed out. Accordingly the depth of the shade of red depends entirely upon the quantity of alumina fixed on the cotton. In a preceding part of this article we have stated the quantity of alumina fixed by this process upon the surface of a square yard of cloth.

In this country common alum is usually employed; but in many parts of the Continent they use acetate of alumina. The high price of that article prevents its employment in Britain. Acetate of alumina, however, is made in this country by the chemical manufacturers, and largely used by the calico-printers. It is made by mixing acetate of lime (obtained by saturating the acetic acid formed when wood is distilled with lime) with a solution of alum, and afterwards drawing off the clear liquor; or by mixing acetate of lead with solution of alum, though that process is more expensive.

Alum (as has been explained under the article ALUM) is a double salt, composed of

3 atoms sulphate of alumina,
1 atom sulphate of potash,
25 atoms water.

To form the alum liquor used by the Turkey-red dyers: To a solution of alum in water of the specific gravity 1·04 as much pearl ash, soda, or chalk is added as is sufficient to precipitate the alumina contained in the alum. Through this muddy liquor, which should have a temperature of from 100° to 120°, the cloth is passed and steeped for twelve hours. The alumina, in the state of extreme division which it has when thus newly precipitated, is readily imbibed by the cloth, and unites with the fibres of the cotton.

12. The cloth thus united to alumina is stove dried, and then washed out of the alum liquor.

13. These essential preliminary steps having been taken, the cloth is ready for being dyed.

The dyeing.

From one to three lbs. of madder reduced to the state of powder for every pound of cloth is employed, the quantity depending upon the shade of colour wanted. The cloth is entered into the boiler when the water is cold. It is brought to boil in one hour, and the boiling is continued for two hours. During the whole of this time the cloth is passed through the dyeing liquor by means of the winch.

For every twenty-five lbs. of cloth dyed, one gallon of bullock's blood is added. This is the quantity of cloth dyed at once in a boiler. This addition of blood is indispensable for obtaining a fine red colour. Various attempts have been made to dispense with the use of blood in Turkey-red dyeing, but hitherto they have been unsuccessful. No satisfactory explanation of the way in which the blood acts has been given. For our own parts, we are disposed to consider the colouring matter of the blood as the useful ingredient. It is probably fixed upon the cloth to a certain extent, and by its fine scarlet tint it is obvious that it must improve the colour of madder red.

14. After the cloth has been thus dyed, it was formerly customary to steep it in a solution the same as that described in No. 7. This was called the *cuing* process. It is now generally dispensed with, and is unnecessary if the cloth has been well cleaned before the galling process. The object of it is merely to dissolve any greasy matter which may continue attached to the cloth, and to form a soap with it, which assists in the subsequent process.

The clearing.

15. Madder contains two colouring matters, a brown and a red. Both are fixed upon the cloth by the dyeing process. The consequence is, that the cloth has a dirty brownish-red colour, which is any thing but agreeable. Fortunately the brown colouring matter is not nearly so *fixed* upon the cloth as the red colouring matter. The next process, called the *clearing process*, is to get rid of the brown colouring matter. For this purpose the cloth is boiled from twelve to fourteen hours, in a mixture of five pounds of soda, eight pounds of soap, and sixteen to eighteen gallons of the residual liquor of No. 9, with a sufficient quantity of water. These quantities are supposed to be employed to clear a hundred pounds of cloth. By this process the brown colouring matter is almost wholly removed, and the cloth begins to assume the fine tint which distinguishes Turkey-red dyed cloth.

16. The next process serves not merely to remove the brown colouring matter more completely, but also to improve the shade of red. Five or six pounds of soap, and from sixteen to eighteen ounces of protochloride of tin, in crystals, are dissolved in water, in a globular boiler, into which the cloth is put. The boiler is then covered with a lid which fits close; and the boiling is conducted under the pressure of two atmospheres, or at the temperature of 250½°. The boiler is furnished with a safety valve and a small conical pipe, the extremity of which has an aperture about $\frac{5}{16}$ths of an inch in diameter, from which there issues a constant stream of steam during the operation. We have given a section and elevation of this boiler in Plate CCVII. fig. 8 and 9, and in fig. 10 a plan of its top, and in fig. 11 of its lid. The use of the salt of tin is to give a shade of scarlet to the cloth. The oxide of tin seems to combine with the oleaginous acid of the soap, and this insoluble soap unites with the red colouring matter of the madder fixed upon the cloth, and improves the shade of colour.

17. After these processes, the cloth is spread out on the grass and exposed to the sun for a few days, which finishes the clearing. It is seldom that recourse is had to a bleaching liquor, consisting of a solution of chloride of lime in water, especially when a salt of lime is used in the cleaning process. When this method is employed, however, one gallon of the solution of chloride of lime, of the specific gravity 1·015, is mixed with twenty gallons of pure water. The cloth is immersed in this dilute solution from five to ten minutes, which is sufficient for completing the clearing.

Remarks on the processes.

Such are the different steps in fixing this beautiful and permanent colour, as practised in the principal works in Glasgow. Many attempts have been made to shorten these tedious processes, but hitherto these attempts have been unsuccessful. The impregnation with oil, or rather with soap, is essential, as is evident from this, that if one, two, or three of these operations be omitted, the red is inferior in proportion to the number of omissions.

Cloth bleached by chloride of lime does not produce a good red. Probably the fibres of the cotton wool are combined with lime, or rather sulphate of lime, which, by decomposing the oleaginous soap, prevents it from being deposited upon and combining with the cloth. But cloth bleached by the old process, namely, boiling in ley or soap, and exposing to the action of the sun, answers perfectly, and will produce as good a red as when unbleached cloth is used; but there would result no saving from bleaching the cloth in this way before commencing the impregnation with the oleaginous soap, because the bleaching is effected betwixt the oil operations by exposing the cloth on the grass.

The colour would be as good without the galls or sumach as with them. But there would be considerable difficulty in sufficiently impregnating the cloth with the solution of alum without its being previously passed through the gall decoction, and more particularly if the cloth be in the least degree greasy. The use of the galls, then, is to facilitate the fixation of the alumina upon the cloth.

Alumina is essential to the fixation of the colour; for without it the madder dye would be fugitive, and would disappear whenever the cloth was washed. The subsequent *clearing* operations would completely remove both the colouring matters of the madder, unless it were cleared along with a quantity of cloth that had received alumina, and been dyed a deep red. In that case the unalumed cloth will receive a little alumina from the alumed portion. This will serve to fix the colour; but as the quantity of alumina which in such a case is imbibed is very small, the red colour will be very pale. It is in this way that the two shades of red, the deep and the pale, which are often seen upon garments and furniture dyed Turkey red, are given. These two shades, by their contrast, frequently add considerably to the beauty of the pattern. The fustic, as well as the tin, probably serves to render the red colour more lively by the shade of yellow which they superinduce.

The three essential processes in the Turkey-red dyeing are, the impregnation with oleaginous soap, the impregnation with alumina, and the dyeing with madder. The last communicates the colour, the second fixes the colour, and the first gives beauty to the colour.

For the better understanding of the Turkey-red processes, we have got drawings made of the principal machinery used.

Fig. 1 and 2, Plate CCVI., exhibit a section and plan of the *liquor tub*, in which the mixture of oil and alkali is put, with its agitators to prevent the oil from separating and swimming on the surface. From the liquor tub (which is placed in an upper room) the liquor passes by a tin pipe to the padding machine, represented in various ways in figs. 3, 4, and 5.

It consists essentially of a box for holding the liquor, through which the cloth passes; and afterwards it goes between two rollers, the distance between which regulates the quantity of liquor which the cloth retains.

a, is the lapper for folding the cloth.

b, a compound lever for regulating the pressure.

c, the box for containing the liquor.

d, a frame or *scrae* for laying the cloth on before it passes through the liquor.

e, pulleys for moving the lapper; and

f, the cylinders between which the cloth passes. They regulate, by their distance from each other, the quantity of liquor allowed to remain in the cloth.

Figs. 6 and 7 represent the elevation and plan of a *dyeing box* on the latest and most improved construction.

a, the winch for moving the cloth through the liquor while dyeing.

b, steam pipe for supplying the vessel with steam.

c, *c*, *c*, the dotted part, represents the valves through which the steam enters into the vessel.

d, *d*, *d*, *d*, divisions of the vessel for different pieces of cloth.

e, catch for stopping or setting on the winch at pleasure.

f, valve for regulating the quantity of steam admitted.

Figs. 8 and 9 represent a section and elevation of the clearing boiler. Fig. 10 represents exactly the mouth of this boiler, and fig. 11 the lid or cover. On the upper edge of this cover there is fixed all round a layer of hemp (a piece of flat rope). The lid is slipt into the inside of the boiler, and by the piece of rope it attaches itself exactly to the inside. The elasticity of the steam within presses it firmly against the inside rim of the mouth, and renders it quite steam-tight.

Scar t with ochi- neal

The scarlet colour communicated to cotton by means of cochineal is far from being permanent; but if this colour is wished to be communicated to cotton, Dr Bancroft recommends to steep the cotton, previously moistened, for half an hour, in a diluted solution of murio-sulphate of tin, and then having wrung the cotton, to plunge it into water in which as much potash has been dissolved as will neutralize the acid adhering to the cotton, so that the oxide of tin may be more copiously fixed on the fibres of the cotton. The stuff being afterwards rinsed in water, may be dyed with cochineal and quercitron bark, in the proportion of four pounds of the former to two and a half or three pounds of the latter. A full bright colour is thus given to the cotton, which will bear slight washings with soap, and exposure to the air. Indeed the yellow part of the colour derived from quercitron bark will bear long boiling with soap, and will resist the action of acids.

Cri on.

With the aluminous mordant, as it is usually applied by calico-printers for madder reds, cotton dyed with cochineal receives a beautiful crimson colour, which will bear several washings, and resist the weather for some time. It is not, however, to be considered as a fixed colour. Dr Bancroft is of opinion that the addition of a small portion of cochineal in dyeing madder reds upon the finer cottons, would be highly advantageous to the calico-printers. By this addition the madder reds are rendered more beautiful, and the fawn colour, or brownish-yellow hue, which injures these colours, would be thus overcome.[1]

SECT. II.—*Of Yellow.*

All the yellow dyes, as well as the red, require a mordant to fix them on the cloth; and the usual mordant employed is alumina. As in the last section, we shall in the first place give an account of the dyestuffs usually employed for giving a yellow colour to cloth, and then give a sketch of the methods employed for giving a yellow colour to wool, silk, cotton, and linen.

I.—*Description of the Dyestuffs.*

The principal colouring matters used in dyeing yellow are *weld*, *fustic*, *catechu*, *anotta*, and *quercitron*. We shall give a short account of these dyestuffs in succession.

Sub nces emp ed in d ng yell Wel

1. *Weld*, in French *gaud* or *vaud*, is the dried leaves and stems of the *reseda luteola*, a plant which grows wild in Britain, and in different European countries. Its leaves are long, narrow, and of a bright green, but the whole plant is made use of in the dyeing of yellow. There are two kinds of weld, cultivated and wild, the former of which is deemed more valuable than the latter, as it yields a much greater proportion of colouring matter. When this plant is fully ripe, it is pulled, dried, and bound up in bundles for the use of the dyer. The wild species grows higher and has a stronger stalk than that which is cultivated, by which the one may be readily distinguished from the other.

A decoction of this plant, if strong, has a brownish-yellow colour, and when diluted with water, it acquires a shade of green. The acids render this colour more pale, while alkalies, common salt, and sal ammoniac, render it deeper; and when sufficient quantities of these substances are dissolved in the decoction, a deep-yellow precipitate falls. A solution of alum or of protochloride of tin throws down a fine yellow lake; sulphate of iron occasions a black precipitate, and sulphate of copper a brownish-green precipitate.

Luteolin.

Chevreul has discovered in weld a yellow colouring matter, to which he has given the name of *luteolin*. It may be sublimed, and in that case it crystallizes in needles, which are transparent, and have a pale-yellow colour. Luteolin dissolves in water, but the solution has little colour; yet silk or woollen previously impregnated with alumina, if passed through it, acquires a fine yellow colour. It is soluble in alcohol and ether. It combines with acids, but still more readily with bases. The compound which it forms with potash has a golden-yellow colour; but when exposed to the air it assumes first a shade of green, and then passes into brown. The compounds of luteolin with the other bases are easily obtained by double decomposition.

The yellow colour communicated by weld is more permanent than that communicated by quercitron or by old fustic.

Fustic.

2. *Fustic*[2] is the name given by the dyers in Great Britain to the wood of the *morus tinctoria*, a tree which grows in the West Indies, and probably also in South America. In France it is distinguished by the name of *bois jaune*. The wood is yellow, as its name imports, with orange veins. Ever since the discovery of America it has been used in dyeing, as appears from a paper in the Transactions of the Royal Society, of which Sir William Petty was the author. Its price is moderate, the colour it imparts is permanent, and it readily combines with indigo, which properties give it a claim to attention as a valuable ingredient in dyeing. Before it can be employed as a dyestuff, it must be cut into chips and put into a bag, that it may not fix in, and tear the stuff, to which it is to impart its colouring matter.

Properties.

When a decoction of yellow wood or fustic is made very strong, the colour is of a reddish yellow, and when diluted it is of an orange yellow, which it readily yields to water. It becomes turbid by means of acids, its colour is of a pale yellow, and the greenish precipitate may be re-dissolved by alkalies. The sulphates of zinc, iron, and copper, as well as alum, throw down precipitates composed of the colouring matter and the different bases of the salts employed.

Morin.

Chevreul discovered in fustic a yellow uncrystallizable colouring matter, to which he has given the name of *morin*. It restores the colour of turmeric paper reddened by lime. It is but little soluble in water, even when boiling hot. Alcohol is a better solvent of it than water, and ether still better than alcohol. When the alcoholic or ether solutions are evaporated, they deposite yellow crystals. The aqueous solution is rendered muddy by gelatine. The solutions of the fixed alkalies and alkaline earths give the aqueous solution a fine yellow colour, without occasioning any precipitate. Alum causes it to assume a greenish-yellow colour. The sulphated peroxide of iron renders it green, and then throws down a precipitate. Concentrated sulphuric acid increases the intensity of the yellow colour, while nitric acid gives it a reddish shade, and renders it muddy. Boiling nitric acid converts it into oxalic acid. By combining with oxygen it seems to assume a red colour. Morin, when distilled, yields a liquid, which crystallizes as it cools, and furnishes a number of yellowish-brown needles. According to the experiments of George, boiling water extracts from fustic 0·15, and alcohol 0·09 of matter; and the wood is composed of

---

[1] *Philosophy of Permanent Colours*, 317.

[2] The origin of the word *fustic* is not very well understood. The French applied the term *Fustet* to the *rhus cotinus* or *Venice sumach*, which yields fugitive and bad yellow. Bancroft supposes that *fustic* is merely a corruption of the word *fustet*. When the morus tinctoria was introduced, about a couple of centuries ago, being the wood of a large tree, it was called *old fustic*, while the rhus cotinus, being only a shrub, was called *young fustic*. Rhus cotinus being now hardly used by dyers, the term fustic has been assigned to the wood of the morus tinctoria.

Lignin	74
Morin	9·1
Tannin	4
Gum	2
Resin	9
	98·1

3. *Catechu*, or *terra japonica*, comes from the East Indies, and is the inspissated decoction of certain plants containing tannin, but principally of the *areka nut*, the wood of *mimosa catechu*, the leaves of the *nauclea catechu*. Areka nuts, cut into small pieces, are sprinkled in an earthen vessel with water holding saltpetre in solution. A portion of the bark of kantai-babela (a species of mimosa) is added. The vessel is closed by a lid luted down with clay, that the temperature may be the higher. After an ebullition of two hours, the fire is gradually diminished during five or six hours. When the vessel is cold the areka nuts are taken out, and the decoction is evaporated down to the consistency of a syrup. It is then kneaded into small balls, and left to dry in the shade.

Constituents.

The principal constituents of catechu are tannin and extractive. The former may be thrown down by gelatine, the latter remains in solution. It has a reddish-brown colour and a sweetish taste. In India catechu is employed in dyeing and calico-printing. The colours which it gives are very various, depending upon the nature of the mordants employed along with it; but they are all very fixed. With verdigris and sal ammoniac the colour is brown; with protochloride of tin yellow; with perchloride of tin a brown, or, if nitrate of copper be added, a deep bronze; with nitrate of alumina a copper red; with nitrate of iron a deep brownish gray.

We are not aware that catechu is employed in this country, either by the dyers or calico-printers; but it is entitled to their attention, both on account of its cheapness, and the permanency and variety of the colours which it gives.

4. *Anotta*, in French *rocou*, is a species of paste of a red colour, obtained from the berries of the *bixa orellana*, Lin. which is a native of America. The anotta of commerce is imported from America to Europe in cakes of two or three pounds weight, where it is prepared from the seeds of the tree mentioned above; but the Americans are said to be in possession of a species of anotta superior to that which they export, both for the brilliancy and permanency of the colour it imparts. They bruise the seeds with their hands moistened with oil, separating with a knife the paste as it is formed, and drying it in the sun; but the seeds are pounded with water when designed for sale, and allowed to undergo the process of fermentation.

According to John, the cakes of anotta are composed of twenty-eight parts of resin mixed with colouring matter, twenty parts of coloured extractive, twenty-six of gum, and twenty of lignin, mixed with an acid and an aromatic substance.

The colouring matter of anotta is but little soluble in water, though it communicates a yellow colour to that liquid. It is more soluble in alcohol, and tinges it orange. Ether dissolves it still better, and assumes also an orange colour. We obtain the colouring matter in a sufficiently pure state by evaporating the alcoholic solution to dryness, treating the residue with ether, and finally distilling off the ether. It is a reddish-brown substance, heavier than water, soft and adhesive. Even when exposed to a very low temperature, it does not become brittle. When heated it melts, and when sufficiently heated in an open vessel it takes fire and burns like a resin.

Its c ur. ing m ter.

We may likewise obtain the colouring matter of anotta by digesting it in a caustic alkaline solution, and then saturating the alkali by an acid. The colouring matter precipitates in orange flocks. Concentrated sulphuric acid gives anotta an indigo-blue colour; but in contact with air this colour soon passes into green, and then into violet brown. Cold nitric acid does not alter the colour of anotta but if the quantity of acid be small, the mixture assumes the consistence of a syrup, and detonates when slightly heated, leaving charcoal. Anotta gives an orange-red colour to oils, both fixed and volatile.

According to Chevreul, anotta contains two different colouring matters, the one yellow and the other red. The yellow colouring matter is soluble in water and alcohol, and slightly in ether; the red colouring matter is scarcely soluble in water, but it dissolves in alcohol and ether, communicating to these liquids an orange-red colour.

Anotta yields an orange precipitate with a solution of alum, and the sulphates of copper and iron produce effects of nearly a similar nature. With a solution of tin the precipitate is of a lemon colour, and slowly deposited.

It is employed both for dyeing silk and cotton, but the colours which it yields have little permanency.

Quei ron bark.

5. *Quercitron bark.*—Quercitron, as it is denominated by Dr Bancroft, is the *quercus nigra* of Linnæus, and is a large tree which grows spontaneously in North America. The bark of it yields a considerable quantity of colouring matter, which was first discovered by Dr Bancroft in the year 1784, in whom the use and application of it in dyeing were exclusively vested for a certain term of years by virtue of an act of parliament. To prepare it for use, the epidermis is taken off and pounded in a mill, the result of which process is a number of filaments and a fine light powder; but as these do not contain equal quantities of colouring matter, it will be proper to employ them in their natural proportions.

Quercitron bark contains a good deal of tannin, and a yellow colouring matter capable of being extracted by water. The aqueous solution, when evaporated to dryness, leaves a quantity of extract, amounting to eight per cent. of the weight of the bark employed. The tannin is that variety which forms a green precipitate with oxide of iron. Its presence is injurious to the beauty of the yellow colour, because it is precipitated by the same re-agents as the colouring matter itself, and of course communicates to it a shade of brown. To free the colouring matter from tannin, ox bladder steeped in water, and deprived of every thing soluble in cold water, is introduced into the quercitron infusion. With this substance the tannin gradually unites, and thus is removed from the solution. It may be thrown down also by a solution of gelatine.

When the infusion of quercitron is gently concentrated, the colouring matter is deposited in crystals, which have a pearly lustre as long as they continue suspended in the liquid. To this colouring matter Chevreul has given the name of *quercitrin*. It restores the yellow colour of turmeric paper reddened by an alkali. It is but little soluble in ether, more soluble in alcohol, and still more soluble in water. The aqueous solution is tinged orange by alkalies. The acetates of lead and copper, and the protochloride of tin, throw it down in yellow flocks. The sulphated peroxide of iron gives it an olive-green colour, and then precipitates it. Sulphuric acid dissolves quercitrin, the solution is orange with a shade of green, and is rendered muddy when mixed with water. When quercitrin is subjected to distillation, it yields, among other products, a liquid which speedily deposites yellow crystals possessing the characters of quercitrin.

Other substances.

Besides the substances already mentioned as employed in the dyeing of yellow, we may add saw-wort to the number (*serratula tinctoria*, Lin.), a plant which yields a colouring matter nearly similar to that of weld, and may of consequence be used as a proper substitute. Dyers' broom (*genista tinctoria*) produces a yellow of very indifferent nature, and is therefore only employed in dyeing stuffs of the coarsest kind. Tumeric (*curcuma longa*) is a native production both of the East and West Indies, and yields a more copious quantity of colouring matter than any other yellow dyestuff; but it will probably never be of any essential service in dyeing yellow, as no mordant has yet been discovered capable of giving permanency to its colour.

Chamomile (*anthemis tinctoria*) yields a faint yellow colour, the hue of which is not unpleasant, but is far from being durable, and even mordants are not capable of fixing it. Sulphate of lime, tartar, and alum, bid fairest for success.

Fenugreck (*trigonella fœnugræcum*) yields seeds which, when ground, communicate to stuffs a pale yellow of tolerable durability; and the best mordants are found to be alum and muriate of soda, or common salt. American hiccory (*juglans alba*) is a tree, the bark of which yields a colouring matter in every respect resembling that of the *quercus nigra*, but in quantity greatly inferior. French berries (*rhamnus infectorius*) produce a tolerable yellow colour, but it is by no means permanent. When used in the process of dyeing, they are to be employed in the same manner as weld. According to Scheffer, a fine yellow colour may be imparted to silk, thread, and wool, by means of the leaves of the willow; but Bergman informs us that only the leaves of the sweet willow (*salix pentandra*) are proper for producing a permanent colour, as a few weeks' exposure to the sun extracts that which is produced by the colouring matter from the leaves of the common willow.

In Switzerland and in England the seeds of purple trefoil are sometimes employed in the art of dyeing, on which Vogler made a number of experiments, in order to ascertain what colours they would produce; and he found that a fine deep yellow was afforded by a bath made of a solution of these seeds with potash; that sulphuric acid yielded a light yellow, and sulphate of copper or blue vitriol a yellow inclining to green. M. Dizé informs us that the seeds of trefoil impart to wool a beautiful orange, and to silk a greenish yellow; and that while aluming is necessary in the process of dyeing with the seeds of trefoil, a solution of tin cannot be employed.

Many other vegetable substances are occasionally employed in dyeing yellow, but it seems useless to enumerate them. Saffron and turmeric yield exceedingly beautiful but fugitive yellows. The colouring matter of saffron (*crocus sativus*) is extremely rich; it has been subjected to a chemical examination, and distinguished by the name of *polychroite* by Bouillon La Grange and Vogler, to whom we are indebted for the first examination of it.

The finest and most fixed of all the yellows on cotton is chromate of lead. It is employed abundantly by the calico-printers, but scarcely by the dyers in general. On that account we think it better to reserve it till we come to that part of this article in which we propose to describe the processes followed by the calico-printers.

II.—*Of the Processes for dyeing Wool Yellow.*

With weld.

In dyeing woollen stuffs with weld, the mordants employed are alum and tartar, and by their means a pure, permanent yellow is obtained. The boiling is to be conducted in the usual way; and, according to Hellot, four ounces of alum to one ounce of tartar are to be employed. Other dyers, however, employ half as much tartar as alum. The colour is rendered paler, but more lively, by means of the tartar.

Preparation of the bath.

The bath is prepared by boiling the plant inclosed in a thin linen bag, and keeping it from rising by means of a wooden cross. Some boil it till it sinks to the bottom of the vessel; while others, after it is boiled, take it out and throw it away. From three to four pounds of weld, and sometimes less, are allowed for every pound of stuff; but the quantity must be regulated by the intensity of the shade desired. Some dyers add a small quantity of quicklime and ashes, which are found to promote the extraction of the colouring matter. These substances at the same time heighten the colour, but render it less susceptible of resisting the action of acids.

For different shades.

With other additions, and different management, different shades may be obtained. Thus lighter shades are produced by dyeing after deeper ones, adding water at each dipping, and keeping the bath at the boiling temperature. These shades, however, are less lively than when fresh baths are employed, with a suitable proportion of weld. The addition of common salt or sulphate of lime to the weld bath communicates a richer and deeper colour. With alum it is paler and more lively, with tartar still paler, and with sulphate of iron the shade inclines to brown. According to Scheffer, by boiling the stuff two hours, with one fourth of its weight of a solution of tin, and the same proportion of tartar, and then washing and boiling it with an equal weight of weld, a fine yellow is produced; but if the stuff be in the state of cloth, its internal texture is not penetrated. Poerner recommends a similar preparation as for dyeing scarlet, and by these means the colour is brighter, more permanent, and lighter.

With quercitron bark.

Dr Bancroft recommends the quercitron bark as one of the cheapest and best substances for dyeing wool yellow. The following is the simple process which he has proposed for its application. The bark is to be boiled up with about its weight, or one third more, of alum, in a suitable proportion of water, for about ten minutes. The stuff previously scoured is then to be immersed in the bath, taking care to give the higher colours first, and afterwards the paler straw colours. By this cheap and expeditious process, colours which are not wanted to be of a full or bright yellow may be obtained. The colour may be considerably heightened by passing the unrinsed stuff a few times through hot water, to which a little clean powdered chalk, in the proportion of about a pound and a half for each 100 lbs. of stuff, has been previously added. The bark, when used in dyeing, being first reduced to powder, should be tied up in a thin linen bag, and suspended in the liquor, so that it may be occasionally moved through it, to diffuse the colouring matter more equally.

Process for permanent colours.

But although the above method possesses the advantages of cheapness and expedition, and is fully sufficient for communicating pale yellows; to obtain fuller and more permanent colours, the common mode of preparation, by previously applying the aluminous mordant, ought to be preferred. The stuff, therefore, should be boiled for about one hour or one hour and a quarter, with one sixth or one eighth of its weight of alum dissolved in a proper proportion of water. The stuff is then to be immersed, without being rinsed, into the dyeing bath, with clean hot water, and about the same quantity of powdered bark tied up in a bag as that of the alum employed in the preparation. The stuff is then to be turned as usual through the boiling liquor, until the colour appears to have acquired sufficient intensity. One pound of clean powdered chalk for every 100 lbs. of stuff is then to be mixed with the dyeing bath, and the operation continued for eight or ten minutes longer. This addition of the chalk raises and brightens the colour.

For different shades.

Orange Yellow.—To communicate a beautiful orange yellow to woollen stuffs, ten lbs. of quercitron bark, tied up in a bag, for every 100 lbs. of stuff, are to be put into the bath with hot water. At the end of six or eight minutes, an equal weight of murio-sulphate of tin is to be added, and the mixture well stirred for two or three minutes. The cloth, previously scoured, and completely wetted, is then immersed in the dyeing liquor, and briskly turned for a few minutes. By this process the colouring matter fixes on the cloth so quickly and equally, that after the liquor begins to boil, the highest yellow may be produced in less than fifteen minutes.

High shades of yellow, somewhat similar to those obtained from quercitron bark by the above process, are frequently given with young fustic (*rhus cotinus*, Lin.), and dyers' spirit, or nitro-muriate of tin; but this colour is much less beautiful and permanent, while it is more expensive, than what is obtained from the bark.

Bright Golden Yellow.—This colour is produced by employing ten pounds of bark for every 100 pounds of cloth, the bark being first boiled a few minutes, and then adding seven or eight pounds of murio-sulphate of tin, with about five pounds of alum. The cloth is to be dyed in the same manner as in the process for the orange yellow.

Bright yellows of less body are produced by employing a smaller proportion of bark, as well as by diminishing the quantity of murio-sulphate of tin and alum. And indeed every variety of shade of pure bright yellow may be given by varying the proportions of the ingredients.

For greenish yellow.

To produce the lively delicate green shade, which, for certain purposes, is greatly admired, the addition of tartar, with the other ingredients, only is necessary, and the tartar must be added in different proportions, according to the shade which is wanted. For a full bright yellow, delicately inclining to the greenish tinge, it will be proper to employ eight pounds of bark, six of murio-sulphate of tin, with six of alum, and four of tartar. An additional proportion of alum and tartar renders the yellow more delicate, and inclines it more to the green shade; but when this lively green shade is wanted in the greatest perfection, the ingredients must be used in equal proportions. The delicate green lemon yellows are seldom required to have much fulness or body. Ten pounds of bark, therefore, with an equal quantity of the other ingredients, are sufficient to dye three or four hundred pounds of stuffs.[1]

For pale green yellow.

To produce the exquisitely delicate and beautiful pale green shades, the surest method, Dr Bancroft observes, is to boil the bark with a small proportion of water, in a separate tin vessel, for six or eight minutes, and then to add the murio-sulphate of tin, alum, and tartar, and to boil them together for about fifteen minutes. A small quantity of this yellow liquor is then to be put into a dyeing vessel which has been previously supplied with water sufficiently heated. The mixture being properly stirred, the dyeing process is to be conducted in the usual way, and the yellow liquor, as it is wanted, gradually added from the first vessel. In this way the most delicate shades of lively green lemon yellows are dyed with ease and certainty. Weld is the only dyestuff from which similar shades of colour can be obtained; but it is four times more expensive. The yellows dyed from quercitron bark, Dr Bancroft adds, with murio-sulphate of tin and alum as mordants, do not exceed the expense of one penny for each pound of stuff, besides a considerable saving of time, labour, and fuel.[2]

Verd used tarta

A greenish shade may also be produced without tartar, by substituting verdigris dissolved in vinegar, along with the bark; but it is neither so permanent, nor so bright and delicate, as that produced by means of tartar. Sulphate of indigo also, in very small proportion, communicates a similar shade when it is employed with the bark, murio-sulphate of tin, and alum; but it is apt to take unequally on the stuff, and besides, in the language of the dyers, the colour has a tendency to *cast* or *fly* in the finishing.

Cochi andm empl

Small proportions of cochineal, employed along with the bark and other ingredients, raise the colour to a beautiful orange, and even to an aurora. Madder may be also employed with the same view, for it heightens the yellow obtained from quercitron bark, although the colour thus obtained is inferior in beauty to that from cochineal. The madder may also be employed with weld for the same purpose.[3]

Colou from citron very ble.

The colours obtained from quercitron bark, by the processes which we have now described, are very durable. They resist the action of the air, of soap, and of acids. It is by the effects of alum, but especially of tartar, that these colours become so fixed as to remain permanent by exposure to the air. It is observed of the highest yellows, even when they approach to the orange, and which are best dyed either with muriate or murio-sulphate of tin and bark, that although they resist the action of soap and acids, they are apt to lose their lustre and become brown by the effect of the sun and air; but this also happens to yellows dyed with nitro-muriate of tin, both with the bark and with weld, but in a still greater degree with other yellow vegetable colouring matters. In some of these this defect is less easily obviated by alum and tartar, than it is in the yellow obtained from weld and quercitron bark.[4]

III.—*Of the Processes for dyeing Silk Yellow.*

With

To dye silk a plain yellow colour, the only ingredient which was formerly employed was weld. The following is the process. The silk being previously scoured in the proportion of twenty pounds of soap to the hundred of stuff, and then alumed, and washed after the aluming, or, as it is called, *refreshed*, the bath is prepared with two pounds of weld for every pound of silk; and having boiled for fifteen minutes, it is to be passed into a vat through a sieve or cloth. When the temperature is such as the hand can bear, the silk is introduced and turned until it has acquired a uniform colour. While this operation is going on, the weld is to be boiled a second time in fresh water; one half of the first bath is taken out, and its place supplied with a fresh decoction. The temperature of the fresh bath may be a little higher than the former; but it is necessary to guard against too great a degree of heat, that the colouring matter already fixed may not be dissolved. The stuff is to be turned as before, and afterwards taken out of the bath. A quantity of soda is to be dissolved in a part of the second decoction, and a larger or smaller proportion of this solution is to be added to the bath, according to the intensity of the shade required. When the silk has been turned a few times, a skain is wrung out, that it may be examined whether the colour be sufficiently full, and have the proper golden shade. To render the colour deeper, and to give it the gold cast, an addition of the alkaline solution is to be made to the bath, and to be repeated till the shade has acquired sufficient intensity. The alkaline solution may also be added along with the second decoction of the weld, observing the precaution that the temperature of the bath be never too great.

[2] *Ibid.* 333.

[3] *Ibid.* 355.

[4] *Ibid.* 334.

For deeper colour.

For other shades.

To produce other shades of yellow, having more of a gold or jonquille colour, a quantity of anotta, proportioned to the shade required, is to be added to the bath along with the alkali. Lighter shades of yellow, such as pale lemon or Canary bird colour, are obtained by previously whitening the silk, and regulating the proportion of ingredients in the bath by the shade required. To communicate a yellow having a tinge of green, a little indigo is added to the bath, if the silk has not been previously azured. To prevent the intensity of the shade from being too great, the silk may be more slightly alumed than usual.

A cheaper process.

But, according to Dr Bancroft, the different shades of yellow obtained from weld may be given to silk with equal facility and beauty, and at a cheaper rate, by employing quercitron bark as a substitute. A quantity of bark powdered and enclosed in a bag, in proportion to the shade of colour wanted, as from one to two pounds for every twelve pounds of silk, is put into the dyeing vat while the water is cold. Heat is then applied; and when it has become rather more than blood warm, or of the temperature of 100°, the silk, having previously undergone the aluming process, is to be immersed and dyed in the usual way. If a deep shade is wanted, a small quantity of chalk or pearl-ashes may be added towards the end of the operation. To produce a more lively yellow, a small proportion of murio-sulphate of tin may be employed; but it should be cautiously used, as it is apt to diminish the lustre of the silk. To produce such a shade, the proportions of the ingredients may be four pounds of bark, three of alum, and two of murio-sulphate of tin. These are to be boiled with a proper quantity of water for ten or fifteen minutes; and the temperature of the liquid being so much reduced as the hand can bear it, the silk is immersed and dyed as usual, till it has acquired the proper colour. Care should be taken to keep the liquor constantly agitated, that the colouring matter may be equally diffused.[1]

For an orange colour.

To dye silk of an aurora or orange colour, after being properly scoured, it may be immersed in an alkaline solution of anotta, the strength of which is to be regulated by the shade required; and the temperature of the bath should be between tepid and boiling water. When the desired shade has been obtained, the silks are to be washed and twice beetled, to free them from the superfluous colouring matter, which would injure the beauty of the colour. When raw silk is to be dyed, that which is naturally white should be selected, and the bath should be nearly cold; for otherwise the alkali, by dissolving the gum of the silk, destroys its elasticity. Silk is dyed of an orange shade with anotta; but the stuffs must be reddened with vinegar, alum, or lemon juice. The acid, by saturating the alkali employed to dissolve the anotta, destroys the yellow shade produced by the alkali, and restores its natural colour, which inclines to a red. But although beautiful colours are obtained by this process, they do not possess any great degree of permanency.

Yellow dye from mushrooms.

Several kinds of mushrooms afford lively and durable yellow dyes. A bright shining dye of this description has been extracted from the *boletus hirsutus*, which commonly grows on walnut and apple trees. The colouring matter is contained both in the tubular part, and also in the parenchyma of the body of the mushroom. To extract the colouring matter, it is pounded in a mortar, and the liquor which is thus obtained is boiled for a quarter of an hour in water. An ounce of liquor is sufficient to communicate colouring matter to six pounds of water. After the liquor has been strained, the stuff to be dyed is immersed in it, and boiled for fifteen minutes. When silk is subjected to this process, after being dyed, it is made to pass through a bath of soft soap, by which it acquires a shining golden yellow colour, which has a near resemblance to the yellow of the silk employed to imitate embroidery in gold. This has been hitherto brought from China, and bears a very high price, the method of dyeing it being unknown in Europe. All kinds of stuff receive this colour; but it is less bright on linen and cotton, and seems to have the strongest affinity for silk. The use of mordants, it is supposed, would modify and improve it greatly.[2]

IV.—*Of the Processes for dyeing Cotton and Linen Yellow.*

Processes with weld.

The process which has been usually followed in dyeing cotton and linen yellow, is by scouring it in a bath prepared in a ley with the ashes of green wood. It is afterwards washed, dried, and alumed, with one fourth of its weight of alum. After twenty-four hours it is taken out of the aluming and dried, but without being washed. The cotton is then dyed in a weld bath, in the proportion of one pound and a quarter of weld for each pound of cotton, and turned in the bath till it has acquired the proper colour. After being taken out of the bath, it is soaked for an hour and a half in a solution of blue vitriol (sulphate of copper), in the proportion of one fourth of the weight of the cotton, and then immersed, without washing, for nearly an hour in a boiling solution of white soap, after which it is well washed and dried.

For a deeper yellow,

A deeper yellow is communicated to cotton by omitting the process of aluming, and employing two pounds and a half of weld for each pound of cotton. To this is added a dram of verdigris, mixed with part of the bath. The cotton is then to be dipped and worked till the colour become uniform It is then taken out of the bath, that a little solution of soda may be added, after which it is returned and kept for fifteen minutes. It is then wrung out and dried.

and other shades.

Other shades of yellow may be obtained by varying the proportion of ingredients. Thus a lemon colour is dyed by using only one pound of weld for every pound of cotton, and by diminishing the proportion of verdigris, or using alum as a substitute.[3]

Cheaper and more permanent colours.

But a better method, as it affords more permanent and more beautiful colours, and at a smaller expense, is recommended by Dr Bancroft. This is by the use of quercitron bark, and the calico-printers' aluminous mordant, or the sugar of lead. The following is the process which he proposes to employ for producing bright and durable yellow colours. One pound of sugar of lead and three pounds of alum are to be dissolved in a sufficient quantity of warm water. The cotton or linen, after being properly rinsed, is to be soaked in this mixture, heated to the temperature of 100°, for two hours. It is then taken out, moderately pressed over a vessel, to prevent the waste of the aluminous liquor. It is then dried in a stove heat, and after being again soaked in the aluminous solution, it is wrung out and dried a second time. Without being rinsed, it is to be barely wetted with lime water, and afterwards dried; and if a full, bright, and durable yellow is wanted, it may be necessary to soak the stuff in the diluted aluminous mordant, and, after drying, to wet it a second time with lime water. After it has been soaked for the last time, it should be well rinsed in clean water, to separate the loose particles of the mordant, which might injure the application of the colouring matter. By the use of the lime-water, a greater proportion of alumina combines with the stuff, besides the addition of a certain proportion of lime.

---

[2] *Philosophical Magazine*, vol. 100.

[3] Berthollet, ii. 267.

Dyeing bath.

In the preparation of the dyeing bath, from twelve to eighteen pounds of powdered quercitron bark are inclosed in a bag for every hundred pounds of the stuff, varying the proportion according to the intensity of the shade desired. The bark is put into the water while it is cold; and immediately after, the stuff is immersed and agitated or turned for an hour or an hour and a half, during which the water should be gradually heated, and the temperature raised to about 120°. At the end of this time the heat is increased, and the dyeing liquor brought to a boiling temperature; but at this temperature the stuff must remain in it only for a few minutes, because otherwise the yellow assumes a brownish shade. The stuff having thus acquired a sufficient colour, is taken out, rinsed, and dried.

Advantage of a diluted mordant.

Dr Bancroft observes, that when the aluminous mordant is employed without the addition of water, one soaking only, and an immersion in lime water, may be sufficient; but he thinks that greater advantage is derived from the application of a more diluted mordant at two different times, or even by the immersion of the stuff a greater number of times, alternately in the diluted aluminous mordant, and lime water, and drying it after each immersion. By this treatment he found that the colour always acquired more body and durability.

Nankeen yellow.

Chaptal has proposed a process for communicating to cotton a nankeen yellow, which, at the same time that it affords a durable colour, has the advantage of being cheap and simple. When cotton is immersed in a solution of any salt of iron, it has so strong an affinity for the oxide, that it decomposes the salt, combines with the iron, and assumes a yellow colour. The process recommended by Chaptal is the following: The cotton to be dyed is put into a cold solution of copperas (sulphate of iron), of the specific gravity 1·02. It is afterwards wrung out, and immediately immersed in a ley of potash of the specific gravity 1·01. This ley must have been previously saturated with a solution of alum. When the stuff has been kept for four or five hours in this bath, it may be taken out, washed, and dried. By varying the proportion of sulphate of iron, every variety of shade of nankeen yellow may be obtained.

By another process.

We shall lay before our readers another process for dyeing nankeen colour, which is proposed and followed by Mr Brewer, a practical dyer. It is as follows:—

"Mix as much sheep's dung in clear water as will make it appear of the colour of grass; and dissolve in clear water one pound of best white soap for every ten pounds of cotton yarn, or in that proportion for a greater or lesser quantity.

"Observe:—The tubs, boards, and poles, that are used in the following preparations must be made of deal; the boiling pan of either iron or copper.

First operation.—"Pour the soap liquor prepared as above into the boiling pan; strain the dung liquor through a sieve; add as much thereof to the soap liquor in the pan as will be sufficient to boil the yarn intended to be dyed, for five hours. When the liquors are well mixed in the pan, enter the yarn, light the fire under the pan, and bring the liquor to boil in about two hours, observing to increase the heat regularly during that period. Continue it boiling for three hours; then take the yarn out of the pan, wash it, wring it, and hang it in a shed on poles to dry. When dry, take it into a stove or other room where there is a fire; let it hang there until it be thoroughly dry.

N. B.—"The cotton yarn, when in the shed, should not be exposed either to the rain or sun. If it is, it will be unequally coloured when dyed.

Second operation.—"In this operation use only one half of the soap that was used in the last, and as much dung liquor (strained as before directed) as will be sufficient to cover the cotton yarn, when in the pan, about two inches. When these liquors are well mixed in the pan, enter the yarn, light the fire, and bring the liquor to boil in about one hour; then take the yarn out, wring it out without washing, and hang it to dry, as in the former operation.

Third operation.—"This operation the same as the second in every respect.

Fourth operation.—"For every ten pounds of yarn make a clear ley from half a pound of pot or pearl ashes. Pour the ley into the boiling pan, and add as much clear water as will be sufficient to boil the yarn for two hours; then enter the yarn, light the fire, and bring it to boil in about an hour. Continue it boiling about an hour, then take the yarn out, wash it very well in clear water, wring it, and hang it to dry, as in former operations.

N. B.—"This operation is to cleanse the yarn from any oleaginous matter that may remain in it after boiling in the soap and dung liquors.

Fifth operation.—"To every gallon of iron liquor[1] add half a pound of ruddle or red chalk (the last the best) well pulverized.

"Mix them well together, and let the liquor stand four hours, in order that the heavy particles may subside; then pour the clear liquor into the boiling-pan, and bring it to such a degree of heat as a person can well bear his hand in; divide the yarn into small parcels, about five hanks in each; soak each parcel or handful very well in the above liquor, wring it, and lay it down on a clean deal board. When all the yarn is handed through the liquor, the last handful must be taken up and soaked in the liquor a second time, and every other handful in succession, till the whole is gone through; then lay the yarn down in a tub, wherein there must be put a sufficient quantity of ley, made from pot or pearl ashes, as will cover it about six inches. Let it lie in this state about two hours, then hand it over in the ley, wring it, and lay it down on a clean board. If it does not appear sufficiently deep in colour, this operation must be repeated till it has acquired a sufficient degree of darkness of colour. This done, it must be hung to dry, as in former operations.

N. B.—"Any degree of red or yellow hue may be given to the yarn, by increasing or diminishing the quantity of ruddle or red chalk.

Sixth operation.—"For every ten pounds of yarn make a ley from half a pound of pot or pearl ashes; pour the clear ley into the boiling pan; add a sufficient quantity of water thereto, that will cover the yarn about four inches; light the fire, and enter the yarn when the liquor is a little warm; observe to keep it constantly under the liquor for two hours; increase the heat regularly till it come to a scald; then take the yarn out, wash it, and hang it to dry, as in former operations.

---

[1] Iron liquor is what the linen-printers use.

Seventh operation.—"Make a sour liquor of oil of vitriol and water. The degree of acidity may be a little less than the juice of lemons; lay the yarn in it for about an hour, then take it out, wash it very well, and wring it; give it a second washing and wringing, and lay it upon a board.

N. B.—"This operation is to dissolve the metallic particles, and remove the ferruginous matter that remains on the surface of the thread after the fifth operation.

Eighth operation.—"For every ten pounds of yarn dissolve one pound of best white soap in clear water, and add as much water to this liquor in your boiling-pan as will be sufficient to boil the yarn for two hours. When these liquors are well mixed, light the fire, enter the yarn, and bring the liquor to boil in about an hour. Continue it boiling slowly an hour; take it out, wash it in clear water very well, and hang it to dry, as in former operations. When dry, it is ready for the weaver.

N. B.—"It appears to me, from experiments that I have made, that less than four operations in the preparation of the yarn will not be sufficient to cleanse the pores of the fibres of the cotton, and render the colour permanent."[1]

Pro s foll d in the st.

A method of giving a very fixed yellow to cotton and linen is practised in the East. It is precisely similar to the plan followed in dyeing Turkey red. The cloth is first impregnated with the oleaginous soap. It is then passed through a decoction of nutgalls, or of some substance containing tannin. The aluminous mordant is then applied. After all these preliminary steps have been accomplished, the cloth is dyed in the usual way with quercitron bark. These complicated processes being precisely similar to those followed by the Turkey-red dyers, we refer the reader for particulars to the fourth division of the first section of the present chapter.

Such processes, however, are unnecessary in this country, because as permanent and beautiful a colour can be given at once to cotton by impregnating it with acetate or nitrate of lead, and then passing the cloth through a solution of bichromate of potash.

SECT. III.—*Of Blue.*

We shall follow the same method in giving an account of the blue dye, as we did when giving an account of the red and yellow dyes; that is to say, we shall first notice the dyestuffs, and then describe the processes followed by the dyers.

I.—*Description of the Dyestuffs.*

The only dyestuff used for giving a blue colour to cloth is *indigo*, a blue pigment obtained from various species of plants. The most common plant yielding indigo is the *Indigofera*, of which there are three species, the *tinctoria*, the *disperma*, and the *argentea*. The *nerium tinctorium*, or rose bay, a tree which is a native of India, also yields it. The method of procuring indigo from these plants, the nature and properties of indigo, and its composition, have been detailed in the article CHEMISTRY in this Encyclopædia, to which therefore we refer the reader.

Co itu- ent f in- dig

Mr Crum has shown that the atomic constituents of indigo are,

16 atoms carbon	12
4 atoms hydrogen	0·5
1 atom azote	1·75
2 atoms oxygen	2
	16·25

Indigo in its perfect state is insoluble in water and alcohol, and has not the property of combining with bases. But when deprived of one atom of oxygen, it assumes a yellow colour, and in that state is capable of combining with lime or potash, and doubtless with other bases, and of forming with them compounds which dissolve in water. When cloth to be dyed is dipt into the indigo vat, rendered soluble by being deprived of an atom of oxygen, and united to a base, it comes out stained yellow. But the basis of the indigo begins immediately to attract oxygen from the atmosphere, and to resume its blue colour. This causes the cloth speedily to become *green* by the mixture of yellow and blue, and finally to assume a deep-blue colour. No mordant is necessary, as there is a strong affinity between indigo and the fibres of the cloth.

Cerulin.

When indigo is digested in concentrated sulphuric acid it undergoes a remarkable change, being converted into a peculiar blue substance, with which the Saxon blue is dyed. To this substance Mr Crum, to whom we are indebted for the first accurate examination of it, has given the name of *cerulin.* Mr Crum has shown that it is a compound of one integrant particle of indigo, and four integrant particles of water.

The mixture of cerulin with sulphuric acid is semifluid, which requires a considerable quantity of water to dissolve it. When potash is added to this solution, a deep-blue precipitate falls, which is a compound of sulphate of potash and cerulin. To this compound Mr Crum has given the name of cerulio-sulphate of potash. All the neutral salts have the property of combining with cerulin, and of precipitating it from its aqueous solution.

Phenicin.

Mr Crum discovered that if the action of sulphuric acid on indigo be stopped at a certain point, a new substance is formed, different from cerulin. To this new substance he gave the name of *phenicin.* It may be obtained by the following process: Digest indigo in sulphuric acid diluted with thrice its weight of water. By this process the indigo is deprived of the greater part of its impurities. Mix one part of this purified indigo with seven or eight parts of concentrated sulphuric acid in a stoppered phial, and agitate the mixture occasionally till it becomes of a bottle-green colour. Then mix it with a large quantity of distilled water, and throw it upon a filter. By continuing to wash the filter, the liquid, which at first passes through colourless, becomes more and more blue, and after some time all the indigo which has been changed passes through. The colourless washings must be thrown away. The blue liquid contains the phenicin in solution, which on the addition of chloride of potassium precipitates of a most beautiful reddish-purple colour, exactly similar to the colour of the vapour of indigo. Its solution is of a fine blue colour like cerulin, but when a neutral salt is added it is precipitated of a fine purple colour. Hence the origin of the term *phenicin.*[2] Mr Crum has shown that it is a compound of one integrant particle of indigo and two integrant particles of water.

Indigo is not confined to plants growing within the torrid zone. The *isatis tinctoria* and *isatis lusitanica*, plants which are cultivated in England and France, yield, when treated in the same way with the leaves of the indigofera, a little indigo; but the quantity is too small to make it worth while to employ these plants for the preparation of this valuable dyestuff. But those plants under the names of *pastel* or *woad* were formerly employed for dyeing blue in all parts of Europe; and it was to prevent any supposed injury to the cultivators of woad that the employment of indigo in dyeing was prohibited in Queen Elizabeth's time in England. The limitations of the use of indigo in France and Saxony were owing to the same cause. So little at that time were the first principles of political economy understood by the rulers of the different kingdoms of Europe.

---

[1] *Edinburgh Magazine*, xxii.

[2] From *φοινιξ, purple.*

Woad is still used by the dyers in some of their processes, but merely for the purpose of de-oxidyzing indigo, and thus rendering it soluble in water.

II.—*Methods of dyeing Wool Blue.*

Preparation of the vat.

The preparation for dyeing blue is made in a large wooden vessel or vat, which should be so constructed as to retain the heat, which is a matter of considerable importance in the process. The vat is therefore set up in a separate place from the coppers, and is sunk so far in the ground as to be only breast-high above it. Before the introduction of indigo, blue was dyed with woad, which furnished a permanent but not a deep colour; but a very rich blue is obtained by mixing indigo with the woad, and these are almost the only substances which are now employed for dyeing woollen stuffs. The proportions of these substances are varied by different dyers, and according to the shade which is required. The following is the account of the preparation of a vat, as it is given by Quatremere. Into a vat of about seven and a half feet deep, and five and a half in diameter, are thrown two balls of pastel or woad, which are previously broken, and together amount to about 400 pounds weight; thirty pounds of weld are boiled in a copper for three hours in a sufficient quantity of water to fill the vat. To this decoction are added twenty pounds of madder and a basket full of bran. The boiling is then continued half an hour longer. This bath is cooled with twenty buckets of water, and after it is settled, and the weld taken out, it is poured into the vat, which must be stirred with a rake all the time that it is running in, and for fifteen minutes longer. The vat is then covered up very hot, and allowed to stand for six hours, when it is uncovered, and raked again for thirty minutes. The same operation must be repeated every three hours. When the appearance of blue streaks is perceived on the surface of the vat, eight or nine pounds of quicklime are added; the colour then becomes of a deeper blue, and the vat exhales more pungent vapours. Immediately after the lime, or along with it, the indigo, which has been previously ground in a mill, with the smallest possible quantity of water, is put into the vat. The quantity is to be regulated by the intensity of the shade required. From ten to thirty pounds may be put into a vat such as we have now described. If on striking the vat with a rake a fine blue scum arises, no other previous preparation is required than to stir it with the rake twice in the space of six hours, to mix the ingredients completely. Great care should be taken not to expose the vat to the air, except during the time of stirring it. When that operation is finished, it is covered with a wooden lid, on which are spread thick cloths, to retain the heat as much as possible; but after all these precautions, at the end of eight or ten days it is greatly diminished, and is at last entirely dissipated, so that the liquor must be again heated, by pouring the greater part of the liquor of the vat into a copper under which a large fire is made. When the liquor has acquired a sufficient temperature, it is returned into the vat, and carefully covered up.

Accidents to which the vat is liable.

Vats of this description are sometimes liable to accidents. A vat is said to be repelled when, having previously afforded fine shades of blue, it appears black, without any blue streaks; and if it be stirred, the black colour becomes deeper; the vat at the same time exhales, instead of a sweetish smell, a pungent odour; and the stuff dyed in a vat in this state comes out of a dirty gray colour. These effects are ascribed to an excess of lime.

Different means are employed to recover a repelled vat. Some are satisfied with merely reheating it, while others add tartar, bran, urine, or madder. Hellot recommends bran and madder as the best remedy. If the excess of lime be not very great, it is sufficient to leave it at rest five or six hours, putting in a quantity of bran and three or four pounds of madder, which are to be sprinkled on the surface, and then it is to be covered up, and after a certain interval to be tried again. But if the vat has been so far repelled as to afford a blue only when it is cold, it must be left at rest to recover, and sometimes must remain whole days without being stirred with the rake. When it begins to afford a tolerable pattern, the bath must be reheated. In general this revives the fermentation. The addition of bran or madder, or a basket or two of fresh woad, produces the same effect.

This vat sometimes runs into the putrefactive process. When this happens, the colour of the vat becomes reddish, the paste rises from the bottom, and a fetid smell is exhaled. This accident is owing to a deficiency of lime, and it must be corrected by adding a fresh quantity. The vat is then to be raked; after two hours more lime is added, and the process of raking again performed. These operations are to be repeated till the vat is recovered.

Nothing requires more attention in treating a vat of this kind than the distribution of the lime, the principal use of which is to moderate the tendency to putrefaction, and to limit the fermentation to that degree which is necessary to deprive the indigo of its oxygen. If too much lime be added, the necessary fermentation is retarded; and if there be too little, the putrefactive process commences.

Two hours previous to the dyeing operation, the vat should be raked; and to prevent the stuff coming in contact with the sediment, which would produce inequalities in the colour, a cross of wood is introduced. The stuff is then to be completely wetted with pure water a little heated, and being wrung out, it is dipped into the vat, where it is moved about for a longer or a shorter time, according to the depth of shade required. During this operation, it is taken out occasionally to be exposed to the air, the action of which is necessary to change the green colour of the bath into a blue. Stuffs dyed blue in this manner must be carefully washed, to carry off the loose particles of colouring matter; and when the shade of blue is deep, they ought even to be cleansed by fulling with soap. This operation does not alter the colour.

What happens in vats of this kind is the separation of an atom of oxygen from the indigo by the action of the fermenting woad. The base of the indigo thus evolved unites to the quicklime, and this compound dissolving in the water, forms the dyestuff. The reason why the air must be so cautiously excluded is, that, by reviving the indigo, it precipitates it from the liquid, and thus deprives the vat of its colouring matter.

Instead of woad, and the other ingredients just mentioned, indigo is deprived of an atom of oxygen, and the base of it dissolved in water by a mixture of bran and potash. Orpiment is also occasionally employed, which has the property of absorbing an atom of oxygen from indigo, and rendering it capable of combining with a base, and of dissolving in water.

The indigo vat employed by the calico-printers is formed by mixing the indigo with the requisite quantity of sulphate of iron to reduce it to its base, and of quicklime to combine with the base evolved, and to cause it to dissolve in water. Such vats are made very deep. The surface, in consequence of exposure to the air, has a blue colour, the indigo being revived. But the liquor, at a little distance from the surface, has a yellow colour. This indeed is the case with all indigo vats. The green colour which they exhibit near the surface is merely the consequence of the mixture of revived indigo with the yellow coloured liquid.

Disco ry of Sa n blue.

The colour which is obtained by dyeing with a solution of indigo in sulphuric acid is known under the name of *Saxon blue*, because the process was first carried on at Grossenhayn, in Saxony, by Counsellor Barth, who made the discovery about the year 1740. This discovery was for some time kept secret, and the method seems to have been originally very complicated. Alumina, antimony, and some other substances, were previously added to the sulphuric acid. These, however, are now omitted, and the indigo alone is dissolved in the acid.

For wol- len st fs.

To produce a Saxon blue colour on woollen stuffs, they are prepared with alum and tartar; and in proportion to the shade required, the quantity of solution of indigo put into the bath must be regulated. When a deep shade of Saxon blue is wanted, the stuff must be passed different times through vessels containing such a quantity of colouring matter as is sufficient to give light colours. In this way, by repeated applications, the colours become more uniform.

We are not aware that Prussian blue is employed as a dyeing material for wool; but it is used to a considerable extent in calico-printing, and has an exceedingly good effect when skilfully used. We shall notice its employment in a subsequent part of this article.

III.—*Processes for dyeing Silk Blue.*

Wit ndi- go.

Silk is dyed blue with indigo alone, without any proportion of woad. The proportion of indigo mentioned in the preparation of the indigo vat, and sometimes a larger proportion, is employed, with six pounds of bran and about twelve ounces of madder. According to Macquer, half a pound of madder for each pound of potash renders the vat greener, and produces a more fixed colour in the silk. When the vat is come to, it should be refreshed with two pounds of potash and three or four ounces of madder, and, after being raked, in the course of four hours it is fit for dyeing. The temperature should be so moderated that the hand may be held in it without uneasiness.

Pre a- tion the

The silk, after being boiled with soap, in the proportion of thirty pounds of soap to a hundred of silk, and well cleaned by repeated beetlings in a stream of water, must be dyed in small portions, because it is apt to take on an uneven colour. When it has been turned once or oftener in the bath, it is wrung out and exposed to the air, that the green colour may change to a blue. When the change is complete, it is thrown into clear water, and afterwards wrung out. Silk dyed blue should be speedily dried. In damp weather and in winter it is necessary to conduct the drying in a chamber heated by a stove. The silk should be hung on a frame kept constantly in motion. To dye light shades, some dyers employ vats that are somewhat exhausted; but it ought to be observed that the colour thus obtained is less beautiful and less permanent than when fresh vats, containing a smaller quantity of indigo, are employed.

For ur- key ue.

Some addition is required to be made to the indigo, to give silk a deep blue. A previous preparation is necessary, by giving it another colour or ground. For the Turkey blue, which is the deepest, a strong bath of archil is first prepared. Cochineal is also sometimes used instead of archil, for the ground, to render the colour more permanent. A blue is given to silk by means of verdigris and logwood, but it possesses little durability. It might be rendered more permanent by giving it a lighter shade in this bath, then dipping it in a bath of archil, and finally in the indigo vat.

Dyeing raw silk.

When raw silk is to be dyed blue, such as is naturally white should be selected. Being previously soaked in water, it is put into the bath in separate hanks, as already directed for scoured silks; and as raw silk is found to combine more readily with the colouring matter, the scoured silk, when it can be conveniently done, should be first put into the bath. If archil, or any of the other ingredients which have been already mentioned, are required to give more intensity to the colour, the mode of application is the same as that directed for scoured silk.

IV.—*Processes for dyeing Cotton and Linen Blue.*

Preparation of the vat.

For dyeing cotton and linen blue, Pileur d'Apligny recommends a vat containing about 120 gallons. From six to eight pounds of indigo, reduced to powder, are boiled in a ley drawn off from a quantity of lime equal in weight to the indigo, and a quantity of potash double its weight. During the boiling, which is to be continued till the indigo is completely penetrated with the ley, the solution must be constantly stirred, to prevent the indigo from being injured by adhering to the bottom of the vessel.

During this process another quantity of quicklime, equal in weight to the indigo, is to be slaked. Twenty quarts of warm water are added, in which is to be dissolved a quantity of sulphate of iron equal to twice the weight of the lime. The solution being completed, it is poured into the vat, which is previously half filled with water. To this the solution of indigo is added, with that part of the ley which was not employed in the boiling. The vat must now be filled up to within two or three inches of the top. It must be raked twice or thrice a day till it is completely prepared, which is generally the case in forty-eight hours, and sometimes sooner, as it depends on the temperature of the atmosphere. A small proportion of bran, madder, and woad, is recommended by some to be added to such a vat as we have now described.

A simpler process.

The process which is followed at Rouen, and described by Quatremere, is simpler. The vats, which are constructed of a kind of flint, are coated within and without with fine cement, and are arranged in one or more parallel lines. Each vat contains four hogsheads of water. The indigo, to the amount of eighteen or twenty pounds, being macerated for a week in a caustic ley strong enough to bear an egg, is ground in a mill; three hogsheads and a half of water are put into the vat, and afterwards twenty pounds of lime. The lime being thoroughly slaked, the vat is raked, and thirty-six pounds of copperas are added; and when the solution is complete, the ground indigo is poured in through a sieve. It is raked seven or eight times the same day, and after being left at rest for thirty-six hours, it is in a state fit for dyeing.

Process on a larger scale.

In extensive manufactories it is necessary to have vats set at different times. In conducting the process of dyeing, the stuffs are first dipped in the most exhausted vat, and then regularly proceeding from the weakest to the strongest, if they have not previously attained the desired shade. The stuffs should remain in the bath only about five or six minutes, for in that time they combine with all the colouring matter they can take up. After the stuffs have been dipped in a vat, it should not be used again till it has been raked, and has stood at least twenty-four hours, unless it has been lately set, when a shorter period is sufficient.

After the stuffs have been dipped three or four times in a vat, it begins to change. It becomes black, and no blue or copper-coloured streaks are seen on the surface after raking it. It must then be renewed by adding four pounds of copperas with two of quicklime, after which it must be raked twice. In this way a vat may be renewed three or four times; but the additional quantity of ingredients must be diminished as the strength of the vat is exhausted.[1]

Process of Bergman. A vat which is still more simple and more easily prepared has been recommended by Bergman. The proportion of the ingredients which he has directed to be employed is the following. To three drachms of indigo reduced to powder, three drachms of copperas, and three of lime, add two pints of water. Let it be well raked, and in the course of a few hours it will be in a proper state for dyeing.

Haussmann's. Haussmann employs a still smaller proportion of indigo. For 3000 lbs. of water he takes thirty-six lbs. of quicklime slaked in 200 lbs. of water, with which the indigo in the proportion of from ten to twenty lbs. well ground is to be mixed. He then dissolves thirty lbs. of copperas in 120 lbs. of hot water. The whole being left at rest for fifteen minutes, the vat is filled, and gently and constantly stirred. When a deeper shade is wanted, and particularly when linen is to be dyed, the proportion of indigo should be greater; but the shade depends very much on the time the stuffs remain in the vat, and the times it has been used. When the vat becomes turbid, the process of dyeing must be interrupted till it has been again raked, and the supernatant liquor become transparent. If the effects of the lime fail, a new quantity, fresh slaked, must be added; and if the iron cease to produce the effect on the indigo, a new portion must be also added, observing the precaution to have a greater quantity of lime than what is necessary to saturate the sulphuric acid. When the indigo seems to be exhausted, fresh portions ground in water are also to be added; the vat is to be raked several times, and allowed to settle, after which it is again fit for use. In this way Mr Haussmann informs us he preserved a vat for the space of two years; and had it not been for the accumulation of sediment, which prevented the stuffs from being immersed to a sufficient depth, it might have been continued in use for a much longer time. It is worth while to add, that Mr Haussmann found that a pattern of cloth dipped in water acidulated with sulphuric acid, immediately after it was taken out of the bath, became of a much deeper blue than a similar pattern exposed to the air, or another dipped in river water.

Another convenient and expeditious vat is mentioned by Bergman and described by Scheffer. Indigo reduced to fine powder, in the proportion of three drachms to a quart, is added to the strong ley of the soap boiler. After a few minutes, when the colouring matter is well penetrated by the ley, six drachms of coloured orpiment are to be added. In a few minutes after the bath has been well raked it becomes green, and the blue streaks appear on the surface. Heat is to be applied, when the operation of dyeing may commence.

The preparation employed for printing cottons is similar to the above bath, excepting in the proportions of orpiment and indigo, which are greater in the former; but these proportions are very different in different manufactories.

English blue. The colour denominated *English blue* is produced by the solution of indigo in sulphuric acid, to which Bancroft gave the improper name of *sulphate of indigo*. To give silk this colour, it is first to be dyed a light blue; and, when taken out of this bath, it is dipped in hot water, washed in a stream, and left in a bath composed of the sulphate of indigo, to which a little of the solution of tin has been added, until the proper shade is obtained, or the bath is exhausted. Previous to its being put into this bath, it may be dipped in a solution of alum, in which it should remain only a very short time. Silk which has been dyed according to thir process is free from the reddish shade which it derives from the blue vat, as well as from the greenish cast of the Saxon blue.[2]

The sulphate of indigo has been hitherto only applied for the purpose of dyeing wool and silk. The affinity of indigo for vegetable substances is not sufficiently strong to effect the decomposition of the sulphate. It cannot, therefore, be employed with advantage in dyeing cotton and linen.

SECT. IV.—*Of Black.*

Though black, considered optically, is not a colour, but the absence of the power of reflecting light, it constitutes a very important colour in the estimation of the dyer.

I.—*Description of the Dyestuffs.*

There are few substances which have the property of producing a permanent black colour without any addition. The juice of some plants produces this effect on cotton and linen. A black colour is obtained from the juice of the *cashew nut*, which will not wash out, and even resists the process of boiling with soap or alkalies. The cashew nut of India is employed for marking linen. That of the West Indies (*anacardium occidentale*, Lin.) also yields a permanent dye, but the colour has a brownish shade. The juice of some other plants, as that of the toxicodendron, or sloes, affords a durable bluish black colour; but these substances cannot be obtained in sufficient quantity, even if they afforded colours equal to those produced by the common processes.

The principal substances which are employed to give a black colour are gallnuts, which contain the astringent principle or tan, and the red oxide of iron.[3] These have been described either in a preceding part of this article, or under the article CHEMISTRY, to which therefore we refer the reader. The black colour is produced by the combination of the astringent principle with the oxide of iron, held in solution by an acid, and fixed on the stuff. When the particles are precipitated from the mixture of tan and a solution of iron, they have only a blue colour; but after they are exposed for some time to the air, and moistened with water, the colour becomes deeper, although the blue shade is still perceptible. After the particles are fixed on the stuff, the shade becomes much deeper.

Logwood is not to be considered as affording a black dye, but is much employed to give a lustre to black colours. We have already described its nature and properties among the substances from which red colouring matters are obtained.

Black colours are rarely produced by a simple combination between the colouring matter and the stuff, but are usually fixed by means of mordants, as in the case of the black particles which are the result of a combination of

---

[1] Berthollet, ii. 90.

[2] *Ibid.* ii. 319.

[3] Oak bark has been recommended as a substitute for gallnuts in dyeing black, and particularly in dyeing hats; and it is said that the colour thus obtained is fuller, more beautiful and durable, while the operation is easier, and less liable to accident. It was first proposed in the year 1782, by Stephanopoli, a Corsican, and a surgeon in the French army. The examination of the process was referred by the French government to Macquer, who gave a favourable report of it; and afterwards to Berthollet, who gave a different opinion. The process has since been examined, and promises to be more economical and advantageous, especially for dyeing hats. (*Phil. Mag.* vi. 176.)

S ple C rs.

the astringent principle and the oxide of iron, held in solution by an acid. But when the particles are precipitated from the mixture of an astringent and a solution of iron, they have only a blue colour. By being exposed to the air, and moistened with water, the colour becomes deeper, although the blue shade is still perceptible. No fine black colour is ever obtained, unless the stuffs are freely exposed to the air. In dyeing black, therefore, the operations must be conducted at different intervals. Berthollet has observed that black stuffs, when brought in contact with oxygen gas, diminish its volume, so that some portion of it is absorbed.

II.—*Of the Processes for dyeing Woollen Black.*

Mu be first-yed blue

In dyeing woollen stuffs black, if a full and fine deep colour is wanted, it is necessary that they be previously dyed of a deep blue colour. To remove all the particles of colouring matter which happen to be loosely attached to the stuff, it should be washed in a river as soon as it is taken out of the vat, and afterwards cleansed at the fulling mill. After these preliminary processes, the stuffs are ready to receive the black colouring matter. The process of Hellot is the following.

He t's pro s.

For every hundred pounds of stuff, ten pounds of logwood, and ten pounds of galls reduced to powder, are put into a bag, and boiled in a middle-sized copper, with a sufficient quantity of water, for twelve hours. A third of this bath is put into another copper, along with two pounds of verdigris. The stuff is immersed in this bath, and continually stirred for two hours. The bath should be kept hot, but it ought not to boil. At the end of two hours the stuff is taken out, and a similar portion of the bath is put into the copper, with eight pounds of copperas (sulphate of iron). During the solution of the copperas the fire is diminished, and the bath is allowed to cool for half an hour, stirring it well the whole time. The remainder of the bath is then to be added, and after making this addition, the bag containing the astringent matters should be strongly pressed, to separate the whole. A quantity of sumach, from fifteen to twenty pounds, is now to be added, and the bath is just raised to the boiling temperature; and when it has given one boil it is to be immediately stopped with a little cold water. A fresh quantity of sulphate of iron, to the amount of two pounds, is then added, and the stuff is kept in it for another hour, after which it is taken out, washed, and aired; it is again put into the copper, and constantly stirred for an hour. It is then carried to the river, well washed, and fulled. To soften the black colour, and make it more firm, another bath is prepared with weld. This is made to boil for a moment, and when it has cooled, the stuff is passed through it. By this process, which is indeed somewhat complicated, a beautiful black colour is produced.

Co on pro s.

But the processes usually followed for dyeing black are more simple. Cloth which has been previously dyed blue is merely boiled in a vat of galls for two hours. It is then kept two hours, but without boiling, in the bath of logwood and sulphate of iron, and afterwards washed and fulled. According to Hellot's process, a bath is to be prepared of a pound and a half of yellow wood, five pounds of logwood, and ten pounds of sumach, which is the proportion of the ingredients for every fifteen yards of deep blue cloth; and the cloth having boiled in this bath for three hours, ten pounds of sulphate of iron are added; the cloth is allowed to remain for two hours longer, when it is taken out to be aired, after which it is again returned to the bath for an hour, and then washed and fulled.

A eaper pro s.

When stuffs are to be dyed at a less expense, instead of the blue ground, a brown or root-coloured ground may be substituted. This brown or fawn colour is communicated by means of the root of the walnut tree, or green walnut peels. The stuffs are then to be dyed black, according to some of the processes already described.

Process of the English dyers.

The proportions of the ingredients employed by the English dyers are, for every hundred pounds of cloth previously dyed a deep blue, about five pounds of sulphate of iron, five pounds of galls, and thirty of logwood. The first step in the process is to gall the cloth, after which it is passed through the decoction of logwood, to which the sulphate of iron has been added.

Arbutus used for galls.

The leaves of the *arbutus uva ursi* have been recommended and employed as a substitute for galls. The leaves must be carefully dried, so that the green colour may be preserved. A hundred pounds of wool are boiled with sixteen pounds of sulphate of iron and eight of tartar for two hours. The day following the cloth is to be rinsed, as after aluming. A hundred and fifty pounds of the leaves of *uva ursi* are then to be boiled for two hours in water, and after being taken out, a small quantity of madder is to be added to the liquor, putting in the cloth at the same time, which is to remain about an hour and a half. It is then taken out and rinsed in water.[1] By this process, it is said, blue cloth receives a pretty good black, but white cloth becomes only of a deep brown. It is said, too, that the madder and tartar are useless ingredients.

Last operation.

After the different operations for dyeing the cloth have been finished, it is washed in a river, and fulled, till the water comes off clear and colourless. Soap suds are recommended by some in fulling fine cloths, but it is found difficult to free the cloth entirely from the soap. After the cloth has come from the fulling-mill, some propose to give it a dip in a bath of weld, by which it is said to be softened, and the colour better fixed; but, according to Lewis, this operation, which in other cases is of some advantage, is useless after the cloth has been treated with the soap suds.

III.—*Of the Processes for dyeing Silk Black.*

In communicating a black colour to silk, different operations are necessary, such as boiling, galling, repairing the bath, dyeing, and softening.

To give a deeper shade to silk, it is necessary to deprive it of the gummy substance to which its stiffness and elasticity are owing. This is done by boiling the silk four or five hours with one fifth its weight of white soap, and afterwards beetling and carefully washing it.

Galling.

In conducting the process of galling silk, three fourths of its weight of galls are to be boiled for three or four hours; but the proportion of galls must depend on their quality. After the boiling, the liquor is allowed to remain at rest for two hours; the silk is then put into the bath, and left there from twelve to thirty-six hours, when it is to be taken out, and washed in the river. But as silk is capable of combining with a great proportion of the astringent principle, or tan, from which it receives a considerable increase of weight, it is allowed to remain for a longer or shorter time, as the silk is required to have more or less additional weight. To communicate, therefore, to silk, what is called a *heavy* black, it is allowed to remain longer in the gall liquor: the process is repeated oftener, and the silk is also dipped in the dye a greater number of times.

Dyeing.

While silk is preparing for the process of dyeing, the bath is to be heated, and should be occasionally stirred, that the grounds which fall to the bottom may not acquire too much heat. It should always be kept under the boiling temperature. Gum and solution of iron are added in different proportions, according to the different processes.

---

[1] *Stockholm Trans.* 1753.

When the gum is dissolved, and the bath near the boiling temperature, it is left to settle for about an hour. The silk, which in general is previously divided into three parts, that each may be successively put into the bath, is immersed in it. Each part is then to be three times wrung, and after each wringing hung up to air. The silk being thus exposed to the action of the air, acquires a deeper shade. This operation being finished, the bath is again heated, with the addition of gum and sulphate of iron; and this is repeated two or three times, according as the black required is light or heavy. When the process of dyeing is finished, the silk is rinsed in a vessel with some cold water, by turning or shaking it over.

Softening.

Silk, after it has been taken out of the dye, is extremely harsh, to remove which it is subjected to the operation of softening. A solution of four or five pounds of soap for every hundred pounds of silk is poured through a cloth into a vessel of water. The solution being completed, the silk is immersed, and allowed to remain in it for about fifteen minutes; it is then to be wrung out and dried.

Dyeing raw silk.

When raw silk is to be dyed, that which has a natural yellow colour is preferred. The galling operation must be performed in the cold, if it be proposed to preserve the whole of the gum, and the elasticity which it gives to the silk; but if part only of the gum is wished to be preserved, the galling is to be performed in the warm bath.

The dyeing operation is also performed in the cold. All that is necessary is to add the sulphate of iron to the water in which the stuff is rinsed. By this simple process the black dye is communicated. It is then washed, once or twice beetled, and dried without wringing, that its elasticity may not be destroyed. Raw silk may be dyed by a more speedy process. After galling, it may be turned or shaken over in the cold bath; and thus, by alternately dipping and airing the stuff, the operation may be completed. It is then to be washed and dried, as in the former process.

A speedier process.

Improved process for velvet.

The method of dyeing velvet at Genoa, which has been simplified and improved in France, is thus described by Macquer. For every hundred pounds of silk, twenty pounds of Aleppo galls, reduced to powder, are boiled in a sufficient quantity of water for an hour. The bath is allowed to settle till the galls have fallen to the bottom; they are then taken out, and two pounds and a half of sulphuric acid, twelve pounds of iron filings, and twenty pounds of gum, are put into a copper vessel, or cullender, furnished with two handles. This vessel is immersed in the bath, and supported that it may not touch the bottom. The gum, which is allowed to dissolve for an hour, is to be occasionally stirred; and if it appear that the whole of the gum is dissolved, three or four pounds more are to be added. Excepting during the operation of dyeing, the cullender is to remain in the copper, which must be kept hot the whole time, but at a temperature below the boiling point. In galling the silk, one third of Aleppo galls is employed, and the stuff should remain six hours in the liquor the first time, and twelve hours the second. By frequent additions of sulphate of iron, and repeated immersions of the stuff, a fine black, according to Lewis, has been obtained. In the above process, the proportion of sulphate of iron is too small; and the gum, according to some, being carried off in the washing, may be considered as useless. Berthollet thinks, that although the quantity be excessive, it has some effect in keeping up the bath; and he adds, if it is to be diminished, it would be useful to add the sulphate of iron in separate portions during each interval.

To diminish the quantity of galls, which are an expensive ingredient in dyeing silk black, other substances have been proposed as substitutes. With this view the following process is recommended.

The silk being boiled and washed, is immersed in a strong decoction of green walnut peels, and allowed to remain till the colouring matter of both is exhausted. It is then to be slightly wrung out, dried, and washed.[1] To give the silk a blue ground, logwood and verdigris are employed, in the proportion of one ounce of the latter for every pound of silk. The verdigris is dissolved in cold water, and the silk is allowed to remain two hours in this solution. It is then immersed in a strong decoction of logwood, slightly wrung out, dried, and afterwards washed at the river. The bath is prepared by macerating two pounds of galls and three of sumach in twenty-five gallons of water, over a slow fire, for twelve hours. The liquid being strained, three pounds of sulphate of iron and the same quantity of gum-arabic are to be dissolved in it. The silk is dipped in this solution at two different times; it is to remain in the bath two hours each time, and it must be aired and dried between each dip. After being twice beetled at the river, it is dipped a third time, and left in the bath four or five hours, after which it is to be dried, washed, and beetled, as before. The temperature of the bath should not exceed 120°. After the first dipping, it may be necessary to add half a pound of sulphate of iron, and an equal quantity of gum-arabic.

Silk which has been previously dyed blue with indigo, it is said, takes only a mealy black; but when it has been prepared with logwood and verdigris, it acquires a velvety lustre. A fine black may be obtained from green walnut peel; but the addition of logwood and verdigris renders a smaller quantity of sulphate of iron necessary, and this is of importance, because it is apt to weaken the silk. The only use of galls, according to some, is to increase the weight of the silk; for the purposes of dyeing, sumach is considered sufficient.[2]

IV.—*Of the Processes for dyeing Cotton and Linen Black.*

It is more difficult to communicate a fine black to linen or cotton than to silk or woollen stuffs. To succeed in producing a black colour of that degree of intensity which will resist soap, it is necessary to adopt particular processes. In dyeing animal matters black, as silk and wool, the best colours are obtained on those which have been previously dyed blue. This also is an essential preliminary process in dyeing linen and cotton black; for it is found that the process which succeeds best is first to give a deep blue grain to the cotton or linen.

The first part of the process is the operation of galling. The stuffs, which have been previously dyed blue, wrung out, and dried, are kept twenty-four hours in the gall liquor, composed of four ounces of galls to every pound of thread. A bath is then prepared of a solution of iron in acetic acid. This solution is obtained by saturating the acid with oxide of iron. In France, vinegar, small beer, or small wine, is employed for this purpose. To promote the acid fermentation, rye meal, or some other substance, is added, and pieces of old iron are thrown into the liquid, which are allowed to remain for six weeks or two months, that the acid may be saturated with the iron. This solution, called *iron liquor* in this country, is prepared from fermented worts, to which old iron is added, as is described above. Five quarts of the iron liquor for every pound of stuffs are put into a vessel. In this the stuffs are wrought with the hand, pound by pound, for fifteen minutes; they are then wrung out and aired. This operation is to be again repeated, taking care to add a fresh quantity of the iron liquor, which should be carefully scummed, after which the stuffs are to be wrung out, aired, and washed at the river. In the next operation, a pound of alder bark for every pound of stuff is boiled in a sufficient quantity of water for an hour. One half of the bath which was employed in the galling, and about one half the quantity of sumach as of alder bark, are then added. The whole is boiled together for two hours, and strained through a sieve. When this liquid is cold, the stuffs are immersed, wrought pound by pound, and occasionally aired. They are afterwards put into the bath, and, after remaining for twenty-four hours, are wrung out and dried. The above is the process which, according to D'Apligny, is followed at Rouen for dyeing cotton and linen.

---

[1] The decoction of walnut peels is prepared by boiling for fifteen minutes, after which it is taken from the fire. After it has subsided, the silk, which has been previously immersed in warm water, is dipped in it.

[2] Berthollet, ii. 20.

The process followed at Manchester, which is described by Mr Wilson, is the following. For the operation of galling, galls or sumach are employed. The stuff is afterwards dyed in a bath consisting of a solution of iron in acetic acid. This bath is also frequently composed of alder bark and iron. After having passed through this bath, the stuff is dipped in a decoction of logwood, to which a small quantity of verdigris has been added. This process is to be repeated till a black of sufficient intensity is obtained, observing to wash and dry after each operation.

According to Guhliche, a solution of iron may be prepared by the following process. A pound of rice is to be boiled in twelve or fifteen quarts of water, till the whole is dissolved. A sufficient quantity of old iron made red hot, to reach half way to the surface of the liquor, is thrown into the solution. The vessel in which the solution is kept must be under cover, but exposed to the air and light, at least for a week. In another vessel, containing a quantity of warm vinegar equal to the solution of rice, an equal quantity of red-hot iron is to be put. This vessel must also be exposed in the same way to the air and light. After several days, the contents of both vessels are mixed together, and the mixture is to be exposed for a week to the open air, after which it is to be decanted and kept for use in a close vessel. To give a sufficient black to linen and cotton, it is only necessary, it is said, to steep them twenty-nine hours in this solution; and if it should appear that the liquor is exhausted of colouring matter, a fresh portion is to be employed. In this way a fine permanent black is obtained. According to the same author, this solution may be advantageously employed as a substitute for sulphate of iron, in dyeing silk and wool. But to give them a fine black, silk and woollen stuffs must be dipped in a decoction of logwood after they are taken from the bath.

SECT. V.—*Of Brown.*

The last of the simple colours is brown. This is also known under the name of *fawn* colour (*fauve*, Fr.). It is that brown colour which has a shade of yellow, and might perhaps be considered as a compound colour, although it is communicated to stuffs by one process.

I.—*Of the Substances employed in Dyeing Brown.*

The vegetable substances which are capable of inducing a fawn or brown colour on different stuffs are very numerous, but those chiefly employed for this purpose are walnut peels and sumach. The peels constitute the green covering of the nut; they are internally of a white colour, which is converted into brown or black by exposure to the air. The skin, when impregnated with the juice of walnut peels, becomes of a brown or almost black colour. When the inner part of the peel, taken fresh, is put into weak oxymuriatic acid, it assumes a brown colour. If the decoction of walnut peels be filtered and exposed to the air, its colour becomes of a deep brown; the pellicles on evaporation are almost black; the liquor detached from these yields a brown extract, completely soluble in water. The colouring particles are precipitated from a decoction of walnut peels by means of alcohol, and they are soluble in water. No apparent change is at first produced by a solution of potash; but it gradually becomes turbid, and the colour is deepened. A copious precipitate, of a fawn colour, approaching to an ash colour, is produced in a decoction of walnut peels, by means of a solution of tin, and the remaining liquor has a slightly yellow tinge.

Properties.

A decoction of walnut peels yields a small quantity of fawn-coloured precipitate by means of a solution of alum, and the liquor remains of the same colour. Sulphate of copper renders it slowly turbid, and throws down a small quantity of precipitate of a brownish-green colour, leaving the supernatant liquor of the same colour. Sulphate of iron deepens the colour; when diluted, the colour becomes brownish green, without the deposition of any sediment. Sulphate of zinc also deepens the colour, and produces no precipitate. The same properties are exhibited by a decoction of the walnut-tree wood, but the colouring matter is not obtained from it in such abundance as from the peels; and the bark may also be used with advantage in dyeing.

Advantages.

The affinity of the colouring matter of walnut peels for wool is very strong; and it readily imparts to it a durable colour, which even mordants do not seem capable of increasing, but they are generally understood to give it additional brightness. A lively and very rich colour is obtained with the assistance of alum. Walnut peels afford a great variety of pleasing shades; and as they require not the intervention of mordants, the softness of the wool is preserved, and the process of dyeing becomes both cheap and simple.

Preparation.

Walnut peels are not gathered till the nuts are completely ripe, when they are put into large casks, along with as much water as is sufficient to cover them. When used in dyeing at the Gobelins in Paris, Berthollet informs us, they are kept for upwards of a year, and very extensively used; but if not made use of till the end of two years, they yield a greater quantity of colouring matter, at which time their odour has become peculiarly disagreeable and fetid. The peels separated from the nuts before they arrive at maturity, may likewise be used in dyeing, but in this state they do not keep so long.

Sumach.

Sumach (*rhus coriaria*, Lin.) is a shrub produced naturally in Palestine, Syria, Portugal, and Spain, being carefully cultivated in the last two of these countries. Its shoots are annually cut down, dried, and reduced to powder in a mill, by which process they are prepared for the purposes of dyeing.

Properties.

The infusion of sumach, which is of a fawn colour with a greenish tinge, is changed into a brown by exposure to the air. A solution of potash has little action on the recent infusion of sumach; its colour is changed to yellow by the action of acids; the liquor becomes turbid by means of alum, a small quantity of precipitate being at the same time formed, and the supernatant liquor remaining yellow. A copious precipitate of a yellowish-green colour is thrown down by sulphate of copper, and the liquor remains clear. No change is speedily produced by muriate of soda (common salt), but it becomes rather turbid at the end of some hours, and its colour is rather clearer. Sulphate of copper produces a copious precipitate of a yellowish green, which after standing some hours changes to a brownish green; the supernatant liquor, which is slightly

Simple Colours.

yellow, remains clear. Sulphate of zinc renders the liquor turbid, darkens its colour, and produces a deep blue precipitate; but when the sulphate of zinc is pure, the precipitate, which is of a brownish fawn colour, is in very small quantity. Acetate of lead gives a copious precipitate of a yellowish colour; the supernatant liquor is of a clear yellow colour. No astringent has so strong a resemblance to galls as sumach; but the precipitate thrown down from an infusion of it by a solution of iron, is not so copious as that which is yielded by an equal quantity of galls, on which account sumach may be generally employed as a substitute for galls, only its quantity will require to be increased.

Bark of birch.

The bark of the birch tree (*betula alba*, Lin.) yields a decoction of a clear fawn colour, but it soon becomes turbid and brown. The addition of a solution of alum, in the open air, produces a copious yellow precipitate; a solution of tin gives also a copious precipitate of a clear yellow colour. With solutions of iron the decoction of the birch tree strikes a black colour, and it dissolves in considerable quantity the oxide of iron, but in smaller proportion than the decoction of walnut peels. On account of this property, it is employed in the preparation of black vats for dyeing thread.

Sandal wood.

Sanders or sandal wood (*Petrocarpus sachtalinus*) is also employed for the purpose of giving a fawn colour. There are three kinds of sandal wood, the white, the yellow, and the red. The last only, which is a compact heavy wood, brought from the Coromandel coast, is used in dyeing. By exposure to the air it becomes of a brown colour; when employed in dyeing, it is reduced to fine powder, and it yields a fawn colour with a brownish shade, inclining to red. But the colouring matter which it yields of itself is in small quantity, and it is said that it gives harshness to woollen stuffs. When it is mixed with other substances, as sumach, walnut peels, or galls, the quantity of colouring matter is increased; it gives a more durable colour, and produces considerable modifications in the colouring matter with which it is mixed. Sandal wood yields its colouring matter to brandy, or diluted alcohol, more readily than to water.

Soot.

Soot communicates to woollen stuffs a fawn or brown colour, of a lighter or deeper shade, in proportion to the quantity employed; but the colour is fading, and its affinity for wool is not great; and besides leaving a disagreeable smell, it renders the fibres harsh. In some manufactories it is employed for browning certain colours, and it produces shades which could not otherwise be easily obtained.

II.—*Of the Processes for dyeing Woollen, &c. a Fawn or Brown Colour.*

With walnut peels.

In dyeing with walnut peels, a quantity proportioned to the quantity of stuff, and the intensity of shade wanted, is boiled for fifteen minutes in a copper. All that is necessary in dyeing with this substance is, to moisten the cloth or yarn with warm water previous to its immersion in the copper, in which it is to be carefully stirred till it has acquired the proper shade. This is the process if the aluminous mordant is not employed. In dyeing cloth, it is usual to give the deepest shades first, and the lighter ones afterwards; but in dyeing woollen yarn, the light shades are given first, and the deeper ones afterwards. An additional quantity of peels is joined to each parcel.

Berthollet's experiments.

Berthollet made a number of experiments to ascertain the difference of colour obtained from the simple decoction of walnut peels, and the addition of metallic oxides as mordants. The oxide of tin, he found, yielded a clearer and brighter fawn colour than that of the simple decoction. The oxide of zinc produced a still clearer colour, inclining to ash or gray. The colour from oxide of lead had an orange cast, while that from oxide of iron was of a greenish brown.[1]

Compo Colou

Dyeing with su mach.

A fawn colour, which has a shade of green, is obtained from sumach alone; but to cotton stuffs which have been impregnated with printers' mordant, or acetate of alumina, sumach communicates a good and durable yellow. Here, however, some precaution is necessary in the use of this substance for this purpose; for as the colouring matter is of so fixed a nature, the ground of the stuff cannot be bleached by exposure on the grass. This inconvenience is avoided by impregnating the whole of the stuff with different mordants, producing in this way a variety of colours, and leaving no part white.

With s dal wo

Vogler employed the tincture of sanders wood for dyeing patterns of wool, silk, cotton, and linen, having previously impregnated them with a solution of tin, and afterwards washing and drying them. Sometimes he used the solution unmixed, and at other times added six or ten parts of water, and in whatever way he employed it he obtained a poppy colour. When the mordant employed was the solution of alum, the colour was a rich scarlet; with sulphate of copper it was a clear crimson, and with sulphate of iron a beautiful deep violet.[2]

CHAPTER V.

OF COMPOUND COLOURS.

Natur compo colours

A mixture of two colouring substances, it is well known, produces a very different shade from that of either of the uncombined colouring matters; hence compound colours are obtained, which are merely mixtures of simple colours. It would undoubtedly be a desirable thing to ascertain with accuracy the peculiar shade produced by the combination of two colouring matters; but these results can only be certainly known by experiment, because by the action of different substances in the bath they are subject to great variations in their effects, according to the affinities which are brought into action, and the new combinations which are formed. What is natural to colouring particles is not to be considered as a constituent part of compound colours, but only the difference of shade which they ought to assume with a particular mordant, or in a particular bath. The effects, therefore, of the chemical agents employed in these processes, and the result of different combinations, ought to be particularly attended to. It is in dyeing compound colours that skill and ingenuity are most conspicuous, and their application of greatest utility, to enable the dyer to vary his processes according to the shade desired, and at the same time to accomplish his operations by the shortest and cheapest means.

Great riety shade

As compound colours are obtained by the mixture of simple colours, very different shades will be obtained from different proportions of the simple colours; hence compound colours exhibit an indefinite variety of shade, and the processes by which they are produced are very numerous. It would extend this treatise to an unusual length were we to attempt to describe every variety of shade which is obtained from the mixture of simple colours. We shall therefore limit our observations to some of the principal compound colours, and an account of the processes by which they are obtained, leaving it to our readers, who have made themselves familiar with the principles already detailed, to vary these colours by employing different proportions and different combinations of simple colouring matters.

---

[1] *Elements of Dyeing*, ii. 296.

[2] *Crell. Ann.* 1790

Compound colours have been usually divided into four classes, namely, green, purple, orange, and gray or drab colour. These are obtained from mixtures of the following simple colours:

1. Blue and yellow produce a green.
2. Red and blue produce a purple, &c.
3. Red and yellow produce orange.
4. Black and other colours produce gray, &c.

The following sections will be occupied in a short detail of the methods which are usually employed in producing these different compound colours.

Sect. I.—*Of the Mixture of Blue and Yellow, or Green.*

Var us shad of gree

Green colours, from the great variety of shades which they exhibit, have been long known by different names, by which the intensity of shade is characterized, such as sea-green, apple-green, meadow or grass-green, pea-green, parrot-green, &c. Many plants afford a green colour, such as brome grass (*bromus secalinus*, Lin.) green berries of *rhamnus frangula*, wild chervil (*chærophyllum sylvestre*, Lin.), purple clover (*trifolium pratense*), common reed (*arundo phragmites*). These colours, however, do not possess sufficient permanency. According to D'Ambourney, indeed, a permanent green may be obtained from the fermented juice of the berries of the berry-bearing alder (*rhamnus frangula*). Having previously prepared the cloth with tartar, solution of nitrate of bismuth, and common salt, he added to the fermented juice of the berries, after it was warmed, a small proportion of acetate of lead; and in this bath he communicated to the cloth an intermediate shade between parrot and grass green. But it is usually from the mixture of blue and yellow that green is obtained; and it may be observed, that it requires much skill and experience, especially in giving light shades, to produce a colour which is uniform and entirely without spots.

I.—*Of the Processes for dyeing Woollen Stuffs Green.*

Co on pr ss.

To dye woollen green, either the yellow or the blue dye may be given to it first. But when the stuff is first dyed yellow, and in this state is introduced into the blue vat, part of the yellow colouring matter being dissolved in the vat, communicates to it a green colour, which renders it unfit for dyeing any other colour than green. To avoid this inconvenience, therefore, the blue colour is first given, and afterwards the yellow. It would be quite unnecessary to resume the account of any part of the processes for dyeing blue, which have been already detailed. It is proper, however, to add, that the intensity of the blue shade must be proportioned to the green, or to the depth of the green colour which is wished to be obtained. Thus, for instance, to produce a parrot green, a ground of sky blue is given, and for the green like that of a drake's neck, a deep blue is required. When the blue dye has been communicated, the yellow is afterwards given, according to some of the processes which have been already described for dyeing yellow. The proper ground being communicated to the cloths, they are washed in the fulling mill, and boiled as for the common process of welding; but when the shade is light, the proportion of salts should be less. Cloths which are to receive light shades are first boiled, and when these are taken out, tartar and alum are added in fresh portions till the cloths which are intended for the darkest shades are boiled. The process of welding is conducted in the same way as for dyeing yellow, with this difference, that a larger proportion of weld is employed, excepting for lighter shades, when the proportion must be smaller. In dyeing green, it is usual to have a succession of shades at the same time; the process is begun with the deepest and ends with the lightest. Between each dip there should be an interval of one half or three quarters of an hour, and at each interval water is added to the bath. It is the practice of some dyers to give each parcel two dips, beginning the first time with the deep shades, and the second with the lighter ones; but when this practice is followed, the time of immersion should be shortened. In dyeing very light shades, the bath should never be permitted to reach the boiling temperature. For deep greens, a browning is given with logwood and a small proportion of sulphate of iron.

Saxon green.

For some kinds of green, sulphate of indigo is employed; and in this case either the blue and yellow are dyed separately, or the whole of the ingredients are mixed together in the bath, and the whole process is finished at a single operation. The colour thus obtained has been distinguished by the name of *Saxon green*. The following is the process recommended by Dr Bancroft.

"The most beautiful Saxon green," says he, "may be produced very cheaply and expeditiously, by combining the lively yellow which results from quercitron bark, murio-sulphate of tin, and alum, with the blue afforded by indigo when dissolved in sulphuric acid, as for dyeing the Saxon blue.

"To produce this combination most advantageously, the dyer, for a full-bodied green, should put into the dyeing vessel after the rate of six or eight pounds of powdered bark in a bag for every 100 pounds weight of cloth, with only a small proportion of water as soon as it begins to grow warm; and when it begins to boil, he should add about six pounds of murio-sulphate of tin (with the usual precautions), and a few minutes after, about four pounds of alum. These having boiled together five or six minutes, cold water should be added, and the fire diminished so as to bring the heat of the liquor nearly down to what the hand is able to bear; and immediately after this, as much sulphate of indigo is to be added as will suffice to produce the shade of green intended to be dyed, taking care to mix it thoroughly with the first solution by stirring, &c.; and this being done, the cloth, previously scoured and moistened, should be expeditiously put into the liquor, and turned very briskly through it for a quarter of an hour, in order that the colour may apply itself equally to every part, which it will certainly do in this way with proper care. By these means, very full, even, and beautiful greens may generally be dyed in half an hour; and during this space it is best to keep the liquor at rather less than a boiling heat. Murio-sulphate of tin is infinitely preferable for this use to the dyer's spirit, because the latter consists chiefly of nitric acid, which, by its highly injurious action upon indigo, would render that part of the green colour very fugitive, as I have found by repeated trials. But no such effect can result from the murio-sulphate of tin, since the muriatic acid has no action upon indigo; and the sulphuric is that very acid which alone is proper to dissolve it for this use.

"Respecting the beauty of the colour thus produced, those who are acquainted with the unequalled lustre and brightness of the quercitron yellows, dyed with the tin basis, must necessarily conclude that the greens composed therewith will prove infinitely superior to any which can result from the dull muddy yellow of old fustic; and in point of expense it is certain that the bark, murio-sulphate of tin, and alum, necessary to dye a given quantity of cloth in this way will cost less than the much greater quantity (six or eight times more) of fustic, with the alum necessary for dyeing it in the common way, the sulphate of indigo being the same in both cases. But in dyeing with the bark, the vessel is only to be filled and heated once, and the cloth, without any previous preparation, may be completely dyed in half an hour: whilst in the common way of producing Saxon greens, the copper is to be twice filled; and to this must be joined the fuel and labour of an hour and a half's boiling and turning the cloth in the course of preparation, besides nearly as much boiling in another vessel to extract the fustic; and after all, the dyeing process remains to be performed, which will be equal in time and trouble to the whole of the process for producing a Saxon green with the bark; so that this colour obtained from bark will not only prove superior in beauty, but in cheapness, to that dyed as usual with old fustic."[1]

II.—*Of the Processes for dyeing Silk Green.*

Preparation.

In giving silk a green colour, greater precaution is necessary, to preserve uniformity of colour, and to prevent spots and stripes. Silk which is intended to receive a green colour is scoured in the same way as for other colours; but for light shades the scouring must be as complete as for blue. Silk which is to be dyed green is first dyed yellow, and being well alumed, it is slightly washed at the river, and divided into small parcels, that it may receive the colouring matter uniformly, and then carefully turned in the weld bath. When the ground is supposed to have acquired a sufficient degree of intensity, a pattern is put into the blue vat to ascertain the proper shade. When this is the case, the silk is taken out of the bath, washed, and immersed in the blue vat. To produce a deeper colour, and at the same time to give variety of shade, a decoction of logwood, fustic, or anotta is added to the yellow bath, after the weld has been taken out. For very light shades, such as apple and sea green, it is scarcely necessary to add, that a weaker ground is to be given. For all light shades, except sea-green, the process is found to succeed better when the yellow is communicated by baths which have been already used; but these baths should not contain any logwood or fustic.

Saxon green.

Saxon green is produced by means of sulphate of indigo. This is a brighter but less durable colour than the former. This process is conducted by boiling as for welding, after which the cloth is washed. Fustic in chips is enclosed in a bag, put into the same bath, and boiled for an hour and a half, when it is taken out, and the bath allowed to cool till the hand can bear it. A pound and a quarter of sulphate of indigo for each piece of cloth of eighteen yards is added. The cloth is at first to be turned quickly, and afterwards more slowly, and it should be taken out before the bath boils. Some dyers put in only two thirds of the solution at first, and after two or three turns take out the cloth and add the other one third. By this means the colour is more uniform.

By one operation.

To produce Saxon green at one operation, the following process is recommended by Dr Bancroft. A bath is prepared of four pounds of quercitron bark, three pounds of alum, and two pounds of murio-sulphate of tin, with a sufficient quantity of water. The bath is boiled ten or fifteen minutes, and when the liquor is so far reduced in temperature as the hand can bear it, it is fit for dyeing. By adding different proportions of sulphate of indigo, various and beautiful shades of green may be obtained, and the colour thus produced is both cheap and uniform. Care should be taken to keep the bath constantly stirred, to prevent the colouring matter from subsiding. Those shades which are intended to incline most to the yellow should be dyed first; and by adding sulphate of indigo, the green having a shade of blue may be obtained. This process, Dr Bancroft observes, is the most commodious and certain for dyeing most beautiful Saxon greens upon silk.[2]

Englis green.

To produce English green, which is more beautiful than common green, and is said to be more durable than the Saxon green, Guhliche gives the following process. He first dyes the silk of a light blue in the cold vat already described, then soaks it in warm water, washes it in a stream, and dips it in a weak solution of alum. He then prepares a bath of sulphate of indigo, one ounce of solution of tin, with the tincture of French berries made with aceto-citric acid. The silk is kept in this bath till it has obtained the desired colour. It is then washed and dried in a shady place. Lighter shades may be dyed afterwards.[3]

III.—*Of the Processes for dyeing Cotton and Linen Green.*

Blue given.

Cotton and linen, after being scoured in the usual way, are first dyed blue, and after being cleansed, they are dipped in the weld bath, to produce a green colour. The strength of the blue and yellow is proportioned to the shade of green which is wanted. But as it is difficult to give to cotton velvet a uniform colour in the blue vat, it is first dyed yellow with turmeric, and the process is completed by giving it a green with sulphate of indigo. The same result, however, will be obtained by commencing the process either with the yellow or the blue.

Proce cotton vet.

The process which D'Apligny describes for dyeing cotton velvet, or cotton thread, a sea or apple green, in one bath, is the following. A quantity of verdigris is dissolved in vinegar, and the mixture is kept excluded from the air in the heat of a stove for fifteen days. A quantity of potash equal in weight to the verdigris employed is dissolved in water, and, four hours before dyeing, it is added to the solution of verdigris. The mixture is to be kept hot. One ounce of alum in five quarts of water for each pound of stuff being prepared, the cotton thread or velvet is soaked in this solution. It is then taken out, and the verdigris being added to the solution of alum, it is again introduced to be dyed.

Olive green.

The different shades of olive green, and drake's neck green, are given to thread after it has received a blue ground, by galling it, and dipping it in a weaker or stronger bath of iron liquor, then in the weld bath, to which verdigris has been added, and afterwards in the bath with sulphate of copper. The colour is lastly to be brightened with soap.

Green from sian b

Cotton dyed with Prussian blue may be dyed green by previously aluming while it is still wet with the blue, and then dipping in a weld bath, the strength of which is proportioned to the shade required. The colour from weld is more lively than that obtained from fustic. But fustic, which gives a deeper shade than weld, and diminishes the brightness of the blue, is to be preferred when a green with an olive shade is wanted.

Gene remar

The shade of green given to any stuff, it is obvious, must vary according to the intensity of the blue shade, the strength of the yellow bath, and the nature of the yellow colouring matter employed. Yellow colours are rendered more intense by means of alkalies, sulphate of lime, and ammoniacal salts; but become fainter by means of acids, alum, and solutions of tin. In dyeing Saxon green the result will be different according to the process which is followed. The effects will be different by adding a yellow to a Saxon blue, from the process in which the sulphate of indigo is mixed with the yellow ingre-

[2] *Ibid.* 346.

[3] Berthollet, ii. 319.

Com und Col rs.

dients; because in the latter case the sulphuric acid has a considerable action on the colouring matter, and thus diminishes the intensity of the yellow. As the particles of indigo have a stronger affinity for the stuff than the yellow colouring matter, in dyeing a succession of shades in a bath in which both are mixed, the bath being first exhausted of the indigo, the last shades incline more to the yellow, on account of the predominance of the yellow colouring matter.

Sect. II.—*Of the Mixture of Red and Blue, or Purple, &c.*

By the mixture of red and blue, violet, purple, dove-colour, lilac, and a great variety of other shades, according to the proportion of the substances employed, or the predominance of the blue or the red, are produced. In stuffs which are to be dyed violet, a deeper blue must be given; for purple colours, the ground requires to be of a lighter blue; but in lilac and other light colours, it is necessary that both the blue and the red have a light shade.

I.—*Of dyeing Wool Violet, Purple, &c.*

In the attempts which have been made to communicate a violet or purple colour to a scarlet ground, according to the observations of Hellot, the colour is very unequal. It becomes therefore necessary to give the blue colour first; and for violets or purples, the shade of blue ought not to be deeper than that of sky blue. The stuff being dyed blue, is boiled with alum, and two fifths of tartar, and is afterwards dipped in a bath composed of nearly two thirds the quantity of cochineal required for scarlet, with the addition of tartar. The same process, indeed, as for dyeing scarlet, is followed. It is a common practice to dye these colours after the reddening for scarlet, making such additions of cochineal and tartar as the intensity of the shade may require.

Lil &c.

For lighter shades, as lilacs, dove-colours, &c. the stuff may be dipped in the bath which has served for violet and purple, and is now somewhat exhausted, taking care to add a quantity of alum and tartar. For reddish shades, such as a peach-blossom, a small proportion of solution of tin is added. It may be observed in general, that although the proportion of cochineal is less in dyeing lighter shades, the quantity of tartar must not be diminished.

Ch per an horter pro ss.

To obtain the same colours, a shorter and less expensive process is recommended by Poerner. In this process he employs sulphate of indigo. He boils the stuff in a solution of alum, in the proportion of three ounces of the latter to one pound of the former, for an hour and a half, and afterwards allows it to remain in the liquid for a night after it has cooled. The dyeing bath is prepared with an ounce and a half of cochineal, and two ounces of tartar, which are boiled for three quarters of an hour: two ounces and a half of sulphate of indigo are then added, the whole is stirred, and boiled gently for fifteen minutes. The dyeing operation is conducted in the usual way, and a beautiful violet is thus obtained. To have all the variety of shades which are produced by the mixture of red and blue, the proportion of the sulphate of indigo is increased or diminished. It is sometimes increased to five ounces, and diminished to five drachms, for each pound of stuff. The quantity of cochineal is also varied, but when it is less than an ounce the colour is dull. Different proportions of tartar are also employed. To produce variety of shades, the stuff is also prepared with different proportions of solution of tin.

Pu le fr log. wo

To communicate a purple colour to wool, as well as some other shades, logwood, with the addition of galls, has been employed. The stuff is previously dyed blue, and, to give a brown shade, sulphate of iron is used; but the colours thus obtained are not permanent. By the following process, described by Decroizille, a durable dye is produced by means of this wood. He dissolved tin in sulphuric acid, to which were added common salt, red acidulous tartrite of potash, and sulphate of copper; or it may be more conveniently done by making a solution of tin in a mixture of sulphuric acid, common salt, and water, to which are to be added the tartrite and sulphate in the state of powder. Of this mordant not less than 1500 quarts were made in twenty-four hours, in a leaden vessel to which a moderate heat was applied. A very lucrative trade was carried on for three years by Decroizille, who sold it at the rate of 1s. 3d. sterling per pound.

Compound Colours.

Process.

If wool in the fleece is to be dyed, it will require a third of its weight of this mordant, while a fifth is a proportion sufficient for stuffs. A bath is prepared of such a degree of temperature as the hand can bear, with which the mordant is properly mixed, and the wool or stuff dipped in it and stirred; the same degree of temperature being kept up for two hours, and increased a little towards the end; after which it is taken out, aired, and well washed. A fresh bath of pure water is prepared at the same temperature, to which is added a sufficient quantity of the decoction of logwood; the stuff is then immersed, stirred, and the heat increased to the boiling temperature, which is to be continued for fifteen minutes, after which, the stuff being taken out, aired, and carefully rinsed, the process of dyeing is completed. If for every three pounds of wool one pound of decoction of logwood has been used, and a proportionate quantity for stuffs which require less, a fine violet colour is produced, to which a sufficient quantity of Brazil wood imparts the shade known in France by the name of *prune de Monsieur*.

Different shades from other substances.

Logwood and Brazil, fustic and yellow wood, are colouring substances which may be fixed with advantage upon wool by means of this mordant. The colour communicated by the two first of these is liable to be changed in the fulling by the action of the soap or urine employed for that purpose; but this change, which is always produced by alkaline substances, is remedied by a slightly acid bath a little hot, called *brightening*, for which the sulphuric acid has the preference. The colour becomes as deep, and frequently much brighter than before the change. Wools which have been dyed by means of this mordant are said to admit of being spun into a finer and more beautiful thread than by the use of alum. If the use of sulphate of copper is omitted, more beautiful colours are produced by fustic and yellow wood, as well as by weld. An orange-red colour is communicated by madder, but not so deep as with a similar quantity of alum. When sulphate of copper is omitted, the wool is said to become much harsher, and the mordant thus prepared yields but indifferent colours with logwood, and in particular with Brazil wood. The use and carriage of this mordant are inconvenient, on account of the heavy sediment by which the vessel is half filled under a corrosive liquor, capable only of being kept in stone ware. These inconveniences may be remedied by the omission of the water in the receipt, which leaves only a paste more conveniently used, and the carriage of it two fifths cheaper.

Nature of the process.

The above process is thus explained by Berthollet. The decomposition of the muriate of soda is effected by the action of the sulphuric acid; and the muriatic acid being thus disengaged, dissolves the tin, part of which is precipitated by means of the tartaric acid, producing the sediment already mentioned. The oxide of copper produces the blue with the colouring particles of the logwood; the violet is formed by the oxide of tin with the same wood, and the red with the colouring matter of the Brazil wood. The same ingenious chemist farther observes, that as an excess of acid is retained in the liquor, it might probably be of advantage to employ acetate as a substitute for sulphate of copper, in which case the action of the free acid would be moderated. He thinks it would still be more advisable to make use of verdigris; because the uncombined part of the oxide of copper would in that case unite with the excess of acid, on which account a smaller quantity of acid would remain in the liquor; and probably the quantity of tartar might be diminished, as a smaller quantity of tin would thus be precipitated.[1]

II.—*Of dyeing Silk Violet or Purple.*

Two kinds of violet. Silk is capable of receiving two kinds of violet colours, denominated the fine and the false, the latter of which is produced by means of archil or Brazil wood. When the fine violet colour is required, the silk must first be passed through cochineal, and dipped afterwards in the vat. The preparation and dyeing of the silk with cochineal are the same as for crimson, with the omission of tartar and solution of tin, by means of which the colour is heightened. The quantity of cochineal made use of is always proportioned to the required shade, whether it is more or less intense; but the usual proportion for a fine violet colour is two ounces of cochineal for each pound of silk. When the silk is dyed it is washed at the river, twice beetled, dipped in a vat more or less strong in proportion to the depth of the violet shade, and then washed and dried with precautions similar to those which all colours require that are dyed in the vat. If the violet is to have greater strength and beauty, it is usual to pass it through the archil bath; a practice which, though frequently abused, is not to be dispensed with for light shades, which would otherwise be too dull.

Purple. When silk has been dyed with cochineal according to the above directions, only a very light shade is requisite for purple; the shades which are deepest are dipped in a weak vat, while dipping them in cold water is sufficient for such as are lighter, the water having been incorporated with a small quantity of the liquor of the vat, because in the vat itself, however weak it might be, they would acquire too deep a tinge of blue. In this manner are the light shades of this colour, such as gilly-flower, peach-blossom, &c. produced by diminishing the quantity of cochineal.

False violets. There are various ways of imparting to silk what are denominated the false violets; but those which are most frequently used, and possessed of greatest beauty, are prepared with archil, the bath of which is, in point of strength, to be suited to the colour required. Having been beetled at the river after scouring, the silk is turned in the bath on the skein sticks; and when the colour is deemed sufficiently deep, a pattern is tried in the vat, to ascertain whether it takes the violet colour intended to be produced. If the shade is found to have acquired the proper depth, the silk is beetled at the river and dipped in the vat, in the same way as for the fine violet colours; and less either of the blue or of the archil colour is given, according as it is meant that the red or blue shade of the violet colour should predominate.

Process of Guhliche. The process recommended by Guhliche for communicating a violet colour to silk is the following. A pound of silk is to be soaked in a bath of two ounces of alum and a like quantity of solution of tin, after having carefully poured off the sediment formed in the mixture. The dye-bath is prepared with two ounces of cochineal reduced to powder, with a drachm of tartar, and the remaining part of the bath, which has answered the purpose of a mordant, with the addition of a sufficient quantity of water. When slightly boiled, such a quantity of solution of indigo is added as may communicate to the bath a proper shade of violet; after which the silk is immersed, and boiled till it has acquired the intended shade. It is then wrung, washed in a stream, and, like every other delicate colour, must be dried in the shade. The light shades exhaust the bath. But it ought to be observed that this colour, which is said to be a beautiful violet, possesses but little durability, and is apt to assume a reddish tinge, owing to the colour of the indigo fading first.

Anoth A violet colour may be imparted to silks by immersing them in water impregnated with verdigris, as a substitute for aluming, and next giving them a bath of logwood, in which they assume a blue colour, which is converted to a violet, either by the addition of alum to the bath, or by dipping them in a weaker or stronger solution of that substance, which communicates a red colour to the particles of logwood. This violet possesses but a small degree of beauty, and little durability; but if alumed silk be immersed in a bath of Brazil wood, and next in a bath of archil, after washing it at the river, a colour is obtained possessing a much higher degree of beauty and intensity. The process described above for dyeing wool succeeds equally well, according to M. Decroizille, in communicating to silk a violet colour.

III.—*Of dyeing Cotton and Linen Violet.*

Comm proces The most ordinary mode by which a violet colour is communicated to cotton and linen stuffs, is first to give them a blue ground in the vat, proportioned to the required shade, and to dry them. They are afterwards galled, in the proportion of three ounces of galls to a pound of stuff, and being left in this bath for twelve or fifteen hours, are wrung out and dried again. They are next passed through a decoction of logwood, and when thoroughly soaked and taken out, the bath receives an addition of two drachms of alum and one of dissolved verdigris for each pound of cotton or thread. The skeins are then dipped again on the skein sticks, and turned for about fifteen minutes, when they are taken out and aired. They are next immersed in the bath for fifteen minutes, taken out, and wrung. To complete the process, the vat employed is emptied; half of the decoction of logwood not formerly made use of is now poured in, with the addition of two drachms of alum, and the thread is again dipped in it till it has acquired the shade proposed, which must always regulate the strength or weakness of the decoction of logwood. This colour resists in a considerable degree the action of the air, but in point of permanency is much inferior to that which is obtained from the use of madder.

SECT. III.—*Of the Mixtures of Yellow and Red, or Orange.*

Orange is the usual result of a composition of yellow and red colours; but an almost endless variety of shades may be produced, according as we vary the proportion of the ingredients, and the particular nature of the yellow made use of. It is sometimes the practice of dyers to combine blue with yellow and red, the result of which is the colour denominated *olive*. Many varieties may be obtained from the use of weld, saw-wort, dyers-weed, and other yellows, and by employing tartar, alum, sulphate of zinc, or sulphate of copper, in the bath, or in the preparation of the cloth.

---

[1] Berthollet, ii. 340.

Com und Col rs.

I.—*Of dyeing Wool Orange.*

Ora e by the s rlet proc .

By a process exactly the same as that which is followed in communicating to stuffs a scarlet colour, an orange may be given to wool; but the quantity of red must be diminished, and that of the yellow increased. If wool is dyed a red colour by means of madder, and afterwards yellow with weld, the resulting compound is a cinnamon colour, and the most proper mordant in this case is a mixture of alum and tartar. The shades may be varied at pleasure by substituting other yellow dyestuffs instead of weld, and by varying the proportions as circumstances may require. Wool may receive a reddish yellow colour by passing it through a madder bath, after it has undergone the usual process for yellow, which has already been described. The strength of the madder bath is always to be proportioned to the shade required. Brazil wood is sometimes employed with yellow substances, or mixed with cochineal and madder. Snuff, chestnut, musk, and other shades are produced by substituting walnut-tree root, walnut peels, or sumach, for weld.

II.—*Of Dyeing Silk Orange, &c.*

Mar e, &c.

Logwood, Brazil wood, and fustic, communicate to silk a marone and cinnamon colour, together with all the intermediate shades. The silk is scoured in the usual manner, alumed, and a bath is prepared by mixing together decoctions of the three different woods mentioned above, made separately, varying the quantity of each according to the shade intended to be given; but the proportion of fustic should be greatest. The silk is turned in the bath on the skein sticks, and when it is taken out, if the colour be uniform, it is wrung and again dipped in a second bath of these three ingredients, according to the effect produced by the first, in order to obtain the shade required.

Oli

The blue vat is not made use of when an olive colour is to be communicated to silk. After being alumed, it is dipped in a bath of weld, which is made very strong. To this is afterwards added the juice of logwood, with a small quantity of solution of alkali when the silk is dipped. This converts it into green, and gives the olive colour. It is dipped again in this bath till it has acquired the shade wanted.

To communicate to it the colour known by the name of *rotten olive*, fustic and logwood are added to the bath after welding, without any alkali. If the colour wanted is to incline more to a red, the addition of logwood alone is sufficient. A sort of reddish olive may likewise be obtained by dyeing the silk in a fustic bath, to which a greater or less quantity has been added of sulphate of iron and logwood.

III.—*Of dyeing Cotton and Linen Orange, &c.*

Cin on colo

A cinnamon colour is communicated to thread and cotton by commencing the process for dyeing them with verdigris and weld; they are afterwards to be dipped in a solution of sulphate of iron, denominated by the French *bain d'assurage*, and then wrung out and dried. As soon as they are dried, they are galled in the proportion of three ounces to the pound of stuff; then dried again, alumed as for red colours, and maddered. After being washed and dried, they are put into hot soap suds, and turned till they have acquired a sufficient degree of brightness. It is the practice of some dyers to add to the aluming a decoction of fustic.

Oliv

By boiling four parts of weld and one of potash in a sufficient quantity of water, M. d'Apligny informs us, a fine olive colour is communicated to cotton and thread. Brazil wood which has been steeped for a night is boiled separately with a small quantity of verdigris, and these solutions are mixed together in various proportions, according to the particular shade required. The thread or cotton is dipped in the compound solution in the usual way.

Compound Colours.

SECT. IV.—*Of the mixture of Black with other Colours.*

Brown.

The compound colours which are obtained from the mixture of black and other colours, are brown, gray, drab, &c. according to the nature and proportions of the simple colours employed.

I.—*Of dyeing Woollen Stuffs Brown, Gray, &c.*

To give a browning to cloth, as soon as it has been dyed, it is dipped in a solution of sulphate of iron, with the addition of an astringent, which makes a *black bath.* It is more common to mix a small quantity of solution of iron with a bath of water, adding more till the dyed stuff dipped in it has received the intended shade. Sulphate of iron is sometimes added to the dye bath; but by dipping the dyed stuff in a solution of this salt, the end is more easily attained. It is the usual practice of M. Poerner to soak the stuff in a solution of sulphate of iron, to which other ingredients are sometimes added; and after having taken it out of the mordant, it is dipped in the dye bath.

Coffee colour.

In order to obtain coffee and damascene colours, with other shades of browns of the common dye, the first method is adopted; a colour more or less deep is communicated to them, according to the shade intended to be obtained by the browning; and a bath is made of galls, sumach, and alder bark, with the addition of sulphate of iron. Those stuffs are first dipped to which the lightest shades are to be communicated, and when these are finished, the browner ones are dipped, a quantity of sulphate of iron being added for each operation, proportioned to the effect intended to be produced.

Gray.

Bluish grays are communicated to stuffs, according to Poerner, by the solution of indigo in sulphuric acid, combined with a mixture of decoction of galls and sulphate of iron, varying the shades according to the different quantities of these ingredients made use of. If to a bath composed of cochineal, fustic, and galls, sulphate of iron be added, other shades are obtained.

For marone, and such other colours as bear a strong resemblance to it, sanders and galls are employed, and sometimes a browning with the addition of logwood. If dyed in the remains of a cochineal bath, these colours may be made to incline to a crimson or purple; and the same effect is produced by adding a small quantity of madder or cochineal to the bath. A little tartar gives a greater degree of brightness to the colour. With a mixture of galls, fustic, and logwood, and a greater or smaller quantity of madder, with the addition of a little alum; those colours may be communicated to stuffs which are known by the name of *hazel.*

Hazel.

Puce colour.

M. Guhliche produces what is called a *puce* colour, by boiling for fifteen minutes a pound of woollen stuff with two ounces of alum, a certain proportion of vinegar and solution of iron, after which he leaves it in the mordant for twelve hours. He then makes a bath with the decoction of two ounces of white galls carefully poured off from the sediment, and mixed with four ounces of madder, in which, when it grows hot, the stuff is immersed, after being taken out of the mordant, allowing it to remain there, while the temperature is gradually increased, till the colour intended has been imparted to it; after which it is boiled for two minutes, washed, and dried in the sun. The colour thus obtained possesses a great degree of durability. It is of a deeper brown by the omission of the alum and vinegar in the mordant; and after these colours the lighter shades are dyed. Sumach may be employed as a substitute for

Compound Colours.

half of the madder. Different brown colours, possessing considerable permanency, may likewise be produced by the use of Brazil and logwood, if more or less of a solution of iron be mixed with a decoction of these substances. The wool being previously alumed and galled, is dyed in it.

II.—*Of dyeing Silk with Mixtures of Black, &c.*

Purple violet.

M. Guhliche imparts to silk a purple violet without a blue ground, with a mixture of one part of galls dissolved in white wine, with three parts of water, in which a pound of silk is macerated for twelve hours, soaked in a mordant made up of two ounces of alum, one ounce of solution of tin, and half an ounce of muriatic acid. After wringing the stuff, it is dyed in a bath composed of two ounces of cochineal and a small quantity of solution of iron, till the intended shade has been communicated; and for shades which are lighter, the residua of these baths are sufficient, either separately or mixed together. Madder may be used in the same way, macerating a pound of silk in a solution of alum mixed with an ounce of muriatic acid and a quantity of solution of iron. When the stuff is wrung out, it is dyed in a bath made of eight ounces of madder. When deeper colours are wanted, some of the solution of galls in white wine is mixed with the madder and cochineal baths.

Silk may be dyed in a bath made of equal parts of Brazil and logwood juice, adding a certain quantity of solution of iron after the stuff has been soaked in a solution of two ounces of alum and an ounce of muriatic acid. If solution of galls be added, the colour becomes deeper.

Brick colour.

Colours resembling that of brick may be produced by immersing silk in an anotta bath, after preparing it with a solution of galls mixed with a certain quantity of solution of iron. By the mixture of Brazil, logwood, archil, and galls, and by a browning with sulphate of iron, a number of different shades are produced; but the whole of them have more or less a tendency to fade, although their brightness is very pleasing to the eye.

III.—*Of dyeing Cotton and Linen with Mixtures of Black, &c.*

With black cask.

A permanent violet colour may be given to thread and cotton, when scoured in the ordinary way, by preparing a mordant with two quarts of the bath of what is called the *black cask*, and four quarts of water, for each pound of stuff, which is made to boil, and the scum is removed which forms on the surface, till it wholly disappears. The liquor is poured into a vat, and, when warm, four ounces of sulphate of copper and one ounce of nitre are dissolved in it. The skeins are left to soak in it for ten or twelve hours, wrung out, and dried. If it is required to produce a deep violet colour, two ounces of verdigris must be added to the bath; and if the nitre be omitted, the colour becomes still deeper by galling the thread more or less prior to its being put into the mordant. If the nitre be increased, and the sulphate of copper be diminished, the violet colour becomes more inclined to lilac. A number of various shades may be produced by different modifications of the mordants employed.

Marone colour.

Cotton is galled, dipped, and wrought in the common way, when different shades of marone colour are wanted. To the bath employed must be added more or less of the liquor of the black cask. The cotton is then washed in a bath mixed with verdigris, next welded, and dyed to a fustic bath, to which a solution of soda and alum is sometimes added. When the cotton prepared in this manner has been thoroughly washed, it is next well maddered, dipped in a weak solution of sulphate of copper, and last of all in soap suds.

Hazel

For some hazel and snuff colours, a browning is communicated to stuffs by means of soot, after the welding and madder bath, to which galls and fustic have been added; sometimes soot is mixed with this bath, and a browning is likewise imparted by means of a solution of sulphate of iron; and for browning colours, walnut peels are sometimes employed as a substitute for solutions of iron. For such wools as are designed for the manufacture of tapestry they are very advantageous, because the colour is not changed into yellow by exposure to the air, as is the case in browning, which is imparted by means of iron, but remains a considerable time without any sensible change. The hue is indeed rather dull, but its goodness and very moderate price are sufficient to recommend a more extensive use of it for grave colours, which in common stuffs are sometimes fashionable.

CHAPTER VI.

OF CALICO-PRINTING.

Calico-printing is the art of communicating different colours to particular parts of the surface of cotton or linen cloth, while the rest of the cloth retains its white colour; or the whole of the cloth may be dyed one colour, as *red* or *blue*, except particular parts, to which some other colours, as yellow, orange, green, &c. are given. The process is not confined to linen and cotton cloth; it may be applied also to silk and woollen cloth; but as the nature of the processes is in all cases the same, it will answer our purpose sufficiently if we give a sketch of the methods followed by the *calico-printers*.

There is a curious passage in Pliny's Natural History, from which it is evident that calico-printing in his time (the first century) was understood and practised in Egypt. The following is a translation of this passage.

"There exists in Egypt a wonderful method of dyeing. The white cloth is stained in various places, not with dye-stuffs, but with substances which have the property of absorbing *(fixing)* colours. These applications are not visible upon the cloth; but when the pieces are dipt into a hot caldron containing the dye, they are drawn out an instant after dyed. The remarkable circumstance is, that though there be only one dye in the vat, yet different colours appear on the cloth; nor can the colours be afterwards removed."[1] It is evident enough that the substances employed to stain the cloth, as Pliny expresses it, were different mordants, which served to fix the dye upon the cloth. Thus if we suppose certain parts of a piece of cotton cloth to be impregnated with alumina, and the cloth afterwards dyed with madder, after the clearing, those parts only impregnated with the mordant would retain their red colour, while the remaining parts will continue white.

The general opinion is, that this ingenious art originated in India, and from that country made its way into Egypt. Whether this notion be well or ill founded, it is certain that calico-printing was known and executed by the Indians at a very early period. Their colours were beautiful and fast, and the varieties of pattern and the number of colours which they understood to fix on different parts of the cloth gave to their printed calicoes a beauty and a value of no ordinary kind; but their processes are so tedious and so clumsy that they could be put in practice only where labour was exceedingly cheap.

---

[1] Plinii *Hist. Nat.* xxxv. 11.

Cico-Prting. Intlu-ced to Eupe.

It is not more than a century and a half since calico-printing was transferred from India to Europe, and little more than a century since it became common in Great Britain. The nations with whom it has made the greatest progress are Switzerland; France, especially in Alsace; some parts of Germany; and Great Britain. In Europe the art has been in a great measure created anew. By the application of machinery, and by the light thrown on the processes by the improvements in chemistry, the tedious methods of the Indians have been wonderfully simplified; and the processes are remarkable for the rapidity with which they are executed, and for the beauty and fastness and variety of the colours which are applied on the surface of cotton and linen cloth.

We shall endeavour in this chapter to give a sketch of the different processes of calico-printing, such as they are at present practised by the most scientific printers in Lancashire, and in the neighbourhood of Glasgow.

The different processes to which the cotton cloth destined to be printed is subjected, are the following: singeing, bleaching, callendering, printing, stoving, dunging, dyeing, brightening.

1. The singeing is intended to remove the fibres of cotton which protrude on the surface of the cloth. This is done by passing the cloth rapidly over the surface of a red-hot iron plate, which burns off all the hairs or protruding fibres of cotton without injuring the cloth. Of late years singeing has been effected by a very ingenious coal gas apparatus. But we need not dwell upon this preliminary process, because the *singeing* has been described already in this Encyclopædia under the article BLEACHING, to which we refer the reader.

2. The methods of *bleaching* and *callendering* cotton have been already given at sufficient length under the article BLEACHING.

Mods of nting.

3. There are two modes of printing; namely, *block-printing* and *cylinder-printing*. The former has been practised from time immemorial; the latter is a modern invention, and originated probably after the introduction of the art of printing into Great Britain. The figure intended to be communicated to the cloth is cut out upon a block of sycamore, the parts which are to make the impression being left prominent, and the rest of the block cut away, just as practised for wooden engravings. When the figure is too complicated, and the lines too fine, to admit of being cut in wood, it is made by means of small pieces of copper, which are very ingeniously driven into the block, and the intervals are filled up with felt. Great patience and ingenuity are displayed in making these blocks for use, and calico-printers are under the necessity of keeping a number of workmen at high wages for that express purpose.

The cylinder is a large circular copper plate, being a circular ruler, several feet long, and several inches in diameter, upon which the different figures to be given to the cloth are engraved; and by its circular motion the whole of these figures are impressed upon the cloth as it moves through under the cylinder. But the usual method of cylinder-printing is to have the intended figures engraven upon a flat copper plate about a square yard (or more) in size. Upon this plate the colour to be applied is spread. It is then pulled. As it passes along, an elastic steel plate called a *doctor* takes off all the colour except that which fills the engraving. It is then pressed against the white cloth, on which it thus leaves exactly the impression of the engraving. This is a very common method of printing pocket handkerchiefs.

Whether the printing is applied by the block, the cylinder, or by flat copper plates, the treatment of the goods is nearly the same.

Calico-Printing.

Most commonly the printing process is applied to fixing mordants on the cloth, which is afterwards dyed in the common way, those parts only retaining the colour which have imbibed the mordant, while the other parts of the cloth remain white. Sometimes it is applied to cloth already dyed, in order to remove the colour from certain portions of it which are either intended to remain white, or to receive some other colour afterwards.

Sometimes it is applied to cloth before it is dyed blue, in order to prevent the indigo from being fixed on those parts to which it is applied, that they may remain white, or be afterwards made to receive other colours. Substances possessed of this property are called resist pastes.

Finally, it is frequently employed to communicate mordants and colouring matter at once to the cloth. Let us take a view of all these different uses.

I.—*Mordants.*

The principal mordants employed by the calico-printers are the following:

How made.

1. *Alumina.*—The usual aluminous mordant of the calico-printers is alum, partly decomposed by acetate of lime. The liquid is made by dissolving alum in water, and adding acetate of lime to the solution. The liquid has a specific gravity of 1·08, and contains about as much alum undecomposed as the liquid can hold in solution.

For particular purposes calico-printers make a mordant by mixing three parts of acetate of lead with four of alum. This mordant consists of a mixture of acetate of alumina and alum, for about a third part of the alum remains undecomposed.

When cloth to be dyed *red* is impregnated with this mordant, it is not thickened. When applied only to particular parts of the cloth by the block or the cylinder, it is thickened with flour or calcined starch, or gum senegal, according to the nature of the style of work.

Chemical colours what.

2. *Oxide of tin.*—Perchloride of tin is very much used as a mordant. The colouring matter is previously mixed with it, and both are applied at once. Such applications are called *chemical colours.* The mixture is allowed to dry on the cloth, which is then merely washed with water. Colours so applied are easily altered by light, soap, &c. Hence, in common language, a *chemical colour* means a fugitive colour. The colours produced in this way are, *pink*, from Brazil wood, peach wood, and cochineal; *purple*, from logwood; and *yellow*, with Persian berries.

Steam colours.

Perchloride of tin is much used in another and pretty common process of the calico-printers, known technically by the appellation of *steam colours.* It is decomposed and converted into stannate of potash. The whole piece of cloth is immersed in the liquid containing the stannate of potash, and dried. The peroxide of tin is then precipitated upon the cloth, by immersing it into a solution of sal ammoniac or sulphate of magnesia, but most commonly into a very weak solution of free sulphuric acid. The different colouring matters previously thickened with starch are then printed on the cloth, and the whole subjected to the action of steam. The consequence is, that by the joint action of moisture and heat, a combination takes place between the colouring matter and the oxide, which is thus rendered insoluble; and no considerable quantity of water is ever present to carry off the colouring matter before it has combined with the mordant.

In this way *pink*, *purple*, and *yellow* are obtained of every variety of shade that can be produced by mixture of these colours with each other, or with Prussian blue.

How used.

3. *Peroxide of iron.*—This metallic oxide is much used as a mordant. It is employed in the state of acetated protoxide of iron, by dissolving metallic iron in pyrolignic

acid.[1] In a few days after being applied to the cloth, especially if exposed to a moist atmosphere, it loses its acid, and the iron becomes peroxidized.

Acetate of iron, of specific gravity 1·05, gives a black with madder. Various shades of purple are obtained by adding different proportions of the mordant and dyestuff. Various shades of *red*, from *brown red* to *pink*, are obtained in the same way, substituting the aluminous mordant of various strengths for the iron. *Chocolates* are got by mixing the aluminous and iron mordants, and then dyeing with madder.

These are the principal mordants employed by the calico-printers. Several substances have so strong an affinity for the cloth that they require no mordant. This is the case with *indigo, sesquioxide of manganese, peroxide of iron,* and *chromate* and *dichromate of lead.*

II.—*Substances used for discharging Colours.*

Most colours are fixed in the cloth, either by means of mordants or by being in a particular state of oxidizement. Thus madder is fixed by means of alumina, and cochineal by means of oxide of tin. Sesquioxide of manganese loses its fixity and is washed away by water the moment that it is converted into protoxide. Hence, when the printers wish to discharge a colour from cloth, they employ something that will dissolve the mordant, or, if no mordant be present, will de-oxidize the colouring matter, which in that case is a metallic oxide. The *dischargers*, then, are either acids, or substances having a strong affinity for oxygen. We shall point out the chief of these, and the way of applying them.

Method of using.

1. *Citric acid* is much used by printers to dissolve alumina and peroxide of iron, and thus to prevent the colours which these mordants would fix from remaining on the cloth. It is obtained by evaporating lemon juice, and thickening it with gum-senegal for the cylinder, or with gum and pipe-clay for the block. It is occasionally assisted by bisulphate of potash or sulphuric acid.

Sometimes the citric acid is printed on white cloth, and the aluminous or iron mordant slightly thickened and dried immediately, to prevent the swelling of the acid figures. At other times the mordants are first applied, and the acids printed over them.

In both cases the goods are afterwards passed through hot water containing cow's dung, and well washed before drying. By this means all the mordant is removed from those parts on which the acid was applied, which of course remains white when the cloth is dyed.

2. *Tartaric acid* thickened with gum is applied by the block or cylinder to cloth previously dyed Turkey red. It is then passed through an aqueous solution of bleaching powder. The acid disengaging the chlorine, the red colour is discharged from those places to which it had been applied, while all the other parts of the cloth retain their red colour.

When oxide of lead is deposited on the cloth along with the acid, and the cloth, after passing through the aqueous solution of bleaching powder, is made to pass through water impregnated with bichromate of potash, the parts which would otherwise have become white are changed into a fine yellow. This beautiful process is not confined to Turkey red.

To discharge manganese.

3. *Protochloride of iron* is used to discharge the manganese brown and substitute a buff. This it does by depriving the manganese of its oxygen, and thus rendering it soluble; while the protochloride of iron converted into perchloride deposites peroxide of iron on the cloth, which combines and produces the characteristic buff or orange colour of that oxide.

Sulphate of iron is used in a variety of ways. It deoxidizes indigo in the indigo vat, and renders it soluble in lime water. It produces *gold, buff,* &c. colours, and makes a good chemical black with logwood.

4. *Protochloride of tin,* when applied to cloth dyed brown by sesquioxide of manganese, immediately reduces it to the state of protoxide, and thus discharges the colour and leaves the parts white. If it be mixed with Brazil wood or cochineal, it discharges the manganese as before, but leaves a pink. When mixed with logwood it leaves a purple, and when with Prussian blue, a blue.

To for yellow.

To produce a yellow upon manganese, ground chloride of tin is mixed with sulphate of lead. The mixture thickened with calcined starch is printed on the manganese brown. As soon as it is dry, the manganese being reduced to the state of protoxide, may be washed off; but the sulphate of lead adheres to the cloth, from an affinity which exists between them. The cloth being now passed through a solution of bichromate of potash, those parts containing the sulphate of lead are dyed a beautiful yellow by the formation of chromate of lead.

To rem iron.

Chloride of tin is capable also of removing peroxide of iron from cloth, by reducing it to protoxide, as it does the sesquioxide of manganese. For this purpose it is printed on a deep colour, composed of peroxide of iron and quercitron yellow. The protochloride of iron is formed and washed away, while the oxide of tin remaining, constitutes a mordant for the quercitron. And thus the parts to which the protochloride of tin was applied become yellow.

The protochloride of tin is also employed occasionally to discharge the orange, consisting of dichromate of lead fixed upon cloth. This it does by reducing the chromic acid to protoxide. As the green oxide of chrome still continues attached to the cloth, the discharged parts do not assume a good white colour. But this does not much affect the blue and purple colours substituted for the orange, by mixing the protochloride of tin with Prussian blue or with logwood.

When protochloride of tin is decomposed by carbonate of soda, protoxide of tin is obtained. This protoxide is used along with potash to render indigo soluble. The protoxide de-oxidizes the indigo, and the potash dissolves the yellow base. It is then applied to the cloth in the way that will be explained afterwards.

III.—*Resist Pastes.*

These pastes are substances which have the property of restoring the blue colour to dissolved indigo, and thus of preventing it from being fixed to those parts of the cloth on which the resist pastes have been applied. Any substance which has the property of parting with oxygen readily answers this purpose. Thus sulphate of copper, or any salt containing black oxide of copper, when put into the indigo vat, instantly revives the indigo, by communicating oxygen to it. The hydrated black oxide has the same effect, and so have the sesquioxide and the deutoxide of manganese.

Nature resist pastes.

The calico-printer's indigo vat is a very deep large vessel filled with water, into which indigo, sulphate of iron, and an excess of lime are put. The lime decomposes the sulphate of iron, and the protoxide of iron thus disengaged coming in contact with the indigo at the bottom of the vat, deprives it of an atom of oxygen, and thus renders it capable of combining with the lime, and of forming a compound which dissolves in water and forms a yellowish-coloured solution. Where this solution is in contact with the atmosphere the indigo is revived, assumes its blue colour, and loses its solubility. Hence the blue scum which always covers the surface; but this scum in some measure protects the rest of the vat. When cloth is dipt into this vat it comes out yellow; but the indigo, from its exposure to the air, gradually absorbs oxygen, so that the cloth becomes at first green, and finally blue. But if to any parts of the cloth before dipping something has been applied which has the property of giving out oxygen to the indigo, all the indigo which would have been imbibed by these parts has been revived before it has had time to come in contact with the cloth; and in the blue state it has not the property of uniting with the cloth, but may be easily washed off. Hence the parts to which the *resist pastes*, as they are called, have been applied, remain white. The principal resist pastes are the following:

---

[1] An impure *acetic acid*, obtained by distilling wood.

Enu era-tion.

1. *Blue paste*, or *vitriol paste*, consists of a mixture of sulphate and acetate of copper, and the solution is thickened with gum-senegal and pipe-clay for the block, and with flour for the cylinder. When the cloth on which this paste has been printed is dipt into the indigo vat, the indigo is oxidized before it reaches the surface of the cloth. After dyeing, the piece is passed through weak sulphuric acid, to remove the oxide of copper which has been precipitated.

2. *Mild paste* consists of sulphate of zinc, gum, and pipe-clay. It is used along with other colours which copper would injure, or which would be destroyed by immersion in sulphuric acid. It resists a pale blue, and the removal of the oxide of zinc afterwards by an acid is not necessary, as when copper is employed.

Sulphate of zinc, as well as all the other metallic salts, and all the acids, precipitate indigo from its solution in lime. It does not revive indigo like the salts of copper; but when the base of indigo is precipitated, it is not so readily fixed as when in a state of solution. The oxide of zinc, with the gum and pipe-clay, act mechanically in keeping it at a distance.

3. *Red paste* consists of the aluminous mordant already described, mixed with acetate of copper, gum, and pipe-clay. It resists pale blues; and the alumina remains upon the portions which are white, to be afterwards dyed with madder and produce a red, or with quercitron for a yellow.

4. *Neutral paste* is the name given by calico-printers to a compound of lime juice, sulphate of copper, gum, and pipe-clay. It resists during a short dip in the blue vat; and the lime juice gives it the property of remaining white when the piece is dyed in madder, even where the preceding aluminous paste goes over it. This acid also prevents the lime of the blue vat from precipitating copper upon the cloth, which would give the cloth a deep-brown tinge in the madder vessel.

5. *Chrome yellow resist paste* consists of a mixture of a salt of copper to resist the blue vat, with a salt of lead to produce a yellow with bichromate of potash after having been dyed blue in the blue vat.

These five constitute the principal resist pastes. There are indeed a few others, but they are of little importance, and they will easily suggest themselves to those who understand the principles of chemistry.

Me ds of g ng the ious colo .

Instead of describing the mode of printing mordants and colouring matters at once, or of applying *chemical colours*, as they are called, we think it will be better to make a few observations on each particular colour in succession, without minding whether it be applied by *dyeing* or *printing*.

1. *Red.*

The usual dyestuff for red among the calico-printers is *madder*. Goods which have received the aluminous mordant applied in figures either by the cylinder or the block, are first passed through hot water containing cow-dung, and well washed. They are then put into a dye vessel along with madder and cold water, to which heat is gradually applied either by means of steam or fire. The pieces are kept constantly moving in the vessel till they have gained the requisite depth of shade, when they are taken out and washed again. The colour given by the madder to those parts of the cloth which have received no mordant, is removed by boiling the cloth in water containing either bran or soap, both of which substances have the property of removing it without injury to the red figure. Afterwards the white portion of the cloth is farther improved by rinsing it in a weak warm solution of bleaching powder.

When *Brazil* wood or *peach* wood is used instead of madder, the mordant and method of dyeing are the same. The cloth, however, does not bear the same treatment after dyeing, and does not require it, because these colours are much more easily removed from the parts of the cloth destitute of mordant.

2. *Pink.*

The most beautiful *pink* to be seen on calico is given by means of cochineal. The mordant is alumina, and the method of proceeding similar to that already described. Madder, when mixed with bran to remove the brown colouring matter, gives what is called a *brown pink.*

Safflower cannot be applied to cloth in figures, but it is frequently employed for giving a uniform pink dye to pieces of cloth. It is first steeped in water containing a carbonated alkali, which dissolves its colouring matter. The solution freed from the fibrous part of the dyestuff is then saturated by an acid, which is commonly *lime juice.* A piece of cloth immersed in this saturated solution extracts the pink colouring matter from it, which is afterwards heightened by immersion in weak cream of tartar. By this means a very beautiful but fugitive colour is communicated.

3. *Yellow.*

The most usual substance now employed by the calico-printers for communicating this colour is *chromate of lead.* The use of this very beautiful and fixed colour does not go farther back than ten or twelve years. The writer of this article endeavoured about fourteen years ago to prevail upon some of the calico-printers in the neighbourhood of Glasgow to try it, but unsuccessfully. At last, after much entreaty, Mr Ramsay, at that time an extensive manufacturer of colours for calico-printers, was induced to make a small quantity of bichromate of potash, so as to put it in the power of those who chose it to try how it would answer. Soon afterwards the use of it was introduced into some of the printing works of France. From that country it soon made its way to Lancashire, and thence to Glasgow. The bichromate of potash, when first prepared, sold as high as a guinea per pound. Of late years it has been as low as tenpence. The method of using this beautiful dyestuff is this:

Acetate or nitrate of lead is applied to the cloth, either by means of the block or cylinder. The cloth is either immediately passed through a solution of bichromate of potash, or the oxide of lead is in the first place set free from its acid by immersing the cloth in lime water, or in some cases into an aqueous solution of bleaching powder. Indeed the processes for applying chromic acid are varied in a great many ways, to suit the different colours which are applied along with the yellow; as in the yellow discharge for bronze, and the yellow resist on blue already described, the yellow discharge on Turkey red, &c. &c.

Quercitron bark is also often employed to communicate a yellow by the calico-printers. The alumina mordant is first applied, and the cloth is cleaned in the dung vessel in the way described when giving an account of madder dyeing. Quercitron bark gives out its colouring matter at a lower heat than madder; and the parts of the cloth to which no mordant has been applied remain tolerably white after the cloth has been washed in cold water.

A decoction of Persian berries constitutes likewise a common yellow dyestuff for calico-printers. The decoction is mixed with the requisite portion of alum to act as a mordant; but a combination between the alumina and the yellow colouring matter takes place without the intervention of a third agent. It is effected either by exposing the cloth to the action of steam, or by putting the piece into water containing an alkali or its carbonate.

4. *Blue.*

The usual dyestuffs for giving a blue colour to calicoes are *indigo* and *Prussian blue.*

The method of forming the indigo vat has been already mentioned. The cloth is dipped in the clear solution. When taken out it is yellow, and gradually becomes blue by absorbing oxygen from the atmosphere. If a deep shade is wanted, the cloth is immersed again, when it receives an additional quantity of indigo, which must be oxidized, as the former was, by exposure to the air. These alternate dips and airings are repeated till the requisite shade is attained.

What is called *pencil blue,* is a solution of indigo in caustic potash or soda, the indigo being de-oxidized by means of orpiment. The solution is thickened by means of British gum, or gum-senegal, and printed upon the cloth either by the block or cylinder. When upon the cloth, the indigo attracts oxygen from the air, and thus becomes blue and fixed. The gum, alkali, loose indigo, &c. are washed away in water.

Prussian blue may be applied to cloth in various ways. We shall mention some of the principal of these.

1. An iron mordant is first applied to the cloth, and allowed to remain untouched till the iron has had time to be peroxidized, and in that way become fixed. The piece is then cleaned as for dyeing, and dipt into a solution of prussiate of potash mixed with sulphuric acid, to disengage the acid or cyanogen which it contains.

2. Prussian blue is dissolved in muriatic acid, oxalic acid, perchloride of tin, or nitrate of iron, and the solution applied immediately to the cloth in the usual way.

3. Ferrocyanic acid is printed upon the cloth, and decomposed by means of a steam heat, hydrocyanic acid escapes, and cyanodide of iron remains in the cloth. It becomes blue by exposure to the air, or by being put into a weak solution of bleaching powder, or of bichromate of potash.

Logwood forms a bluish compound with the salts of copper; but this colour is exceedingly fugitive, and the use of it has been long laid aside.

5. *Black.*

Various methods are employed by the calico-printers to produce a black upon cotton. An iron mordant of the specific gravity 1·05 gives a black with madder. The common aluminous mordant gives a black when cloth impregnated with it is dyed in logwood. A chemical black is made from a decoction of nutgalls mixed with nitrated peroxide of iron. Another chemical black is formed by mixing a decoction of logwood with a solution of sulphate of iron.

If cloth be dyed successively *blue, red,* and *yellow,* it becomes *black.*

6. *Buff.*

To produce this colour, the cloth is printed with a mixture of sulphate and acetate of iron. After having had time to be partly peroxidized and partially decomposed, it is washed in water; or if a stronger buff is wanted, it is rinsed in cream of lime till the protoxide is converted into the red. No mordant is required, as the peroxide of iron has a strong affinity for cotton cloth.

7. *Gold.*

For this colour the process is the same as for buff. The only difference is, that the solution is stronger.

8. *Orange.*

The most beautiful orange is given by means of dichromate of lead. It is obtained by saturating bichromate of potash with potash or lime, and immersing in it while hot, cloth printed with a salt of lead. Nitric acid changes this orange into yellow, by uniting with half the oxide of lead.

9. *Green.*

The fast green, discovered by Mr James Thomson of Primrosehill, near Clitheroe, and commonly known by the name of *Warwick's green,* is a mixture of the pencil blue already described, and aluminated potash. The mixture is thickened and applied as the blue is. The alumina is then precipitated from its alkaline solution by being passed through a weak solution of sal ammoniac or sulphate of magnesia. The cloth is then dyed yellow in quercitron bark. It is sufficiently known that the two colours blue and yellow form a green.

Carbonate of copper makes a poor faint *green* upon cloth, while the hydrated black oxide forms a bright *blue.* It is obtained by printing on a strong solution of copper, and dipping the cloth, when dry, into strong caustic potash or soda.

The colour called *Scheele's green* is a mixture of arsenite of copper and the hydrated black oxide. It is obtained by printing on the cloth a strong solution of copper thickened with gum, and then dipping it into a mixture of arsenite of potash and caustic potash. Hot water destroys this colour, by depriving the oxide of copper of its water.

A *green* is obtained from Prussian blue and yellow berries, by mixing together ferrocyanic acid, yellow berries, and an aluminous mordant, and subjecting them to the action of steam.

Various other greens are attained by printing yellows over blues previously produced.

Saxon green is produced by printing a solution of cerulin over a yellow formed by dyeing the aluminous mordant with quercitron bark or weld. The cerulin adheres to those parts of the cloth which have been dyed yellow, but very slightly to the white cloth, from which it is easily washed away.

10. *Lilac.*

This colour is communicated to cloth by printing on a much diluted mixture of the iron and aluminous mordants thickened with gum-senegal. The cloth is then dyed in madder exactly as described for producing a red.

11. *Chocolate.*

The same mordants, but much stronger, and dyeing in madder in the same way, produces this colour.

12. *Purple.*

The iron mordant, diluted to the shade required, is printed on the cloth, which is then dyed in madder in the usual way.

When the cloth, after a weak aluminous mordant has been printed on it, is dyed in logwood, a *purple* colour is obtained.

13. *Brown.*

By far the finest and most fixed brown is communicated to cotton by means of the sesquioxide of manganese. The process is rather a recent one, but of late years it has become very general. A neutral solution of sulphate of manganese is thickened with gum, and printed on the cloth. It is then dipped into rather strong caustic potash ley, which precipitates the protoxide of manganese. By exposure to the air, or by immersion in bleaching powder solution, or in bichromate of potash, this protoxide absorbs more oxygen, and becomes fixed on the cloth. Though the state of oxidizement has not been determined by experiment, yet it is probable that the manganese is in the state of red oxide, which is a compound of two atoms sesquioxide and one atom protoxide.

14. *Drab.*

This is made by printing on an iron mordant, and then dyeing in quercitron bark.

15. *Olive.*

Formed by printing on a mixture of the iron and aluminous mordants, and dyeing in quercitron bark.

16. *Dove.*

A weak iron mordant dyed in cochineal.

17. *Slate.*

A weak iron mordant dyed in nutgalls or in sumach.

18. *Cinnamon.*

The aluminous mordant, with the addition of a little iron, dyed in a mixture of madder and quercitron bark.

Such are the principal colours given to calicoes, and such are the methods of applying and fixing them.

We have now finished our account of calico-printing; for the dunging and brightening processes have been described while treating of the various colours; and the *stoving*, which consists simply in drying the goods in a room raised by artificial heat to a temperature higher than the boiling point of water, requires no description.

(L.)

DYER, Sir James, an eminent English lawyer, chief judge of the court of common pleas in the reign of Queen Elizabeth. He died in 1581; and about twenty years afterwards was published his large collection of Reports, which have been highly esteemed for their succinctness and solidity. He also left other writings behind him relative to his profession.

Dyer, *John*, the son of Robert Dyer, a Welsh solicitor of great capacity, was born in 1700. He passed through Westminster school under the care of Dr Freind, and was then called home to be instructed in his father's profession. His genius, however, led him a different way; for besides his early taste for poetry, he had a passion no less strong for the arts of design, and determined to make painting his profession. With this view, having studied some time under a master, he became, as he tells his friend, an itinerant painter, and wandered about South Wales and the parts adjacent. About 1727 he printed *Grongar Hill*. Being probably dissatisfied with his own proficiency, he made the tour of Italy, where, besides the usual study of the remains of antiquity, and the works of the great masters, he frequently spent whole days in the country about Rome and Florence, sketching those picturesque prospects with facility and spirit. Images drawn from thence naturally transferred themselves into his poetical compositions; the principal beauties of *The Ruins of Rome* are perhaps of this kind; and the various landscapes in *The Fleece* have been particularly admired. On his return to England he published *The Ruins of Rome*, 1740; but soon found that he could not relish a town life, nor submit to the assiduity required in his profession. As his turn of mind was rather serious, and his conduct and behaviour were always irreproachable, he was advised by his friends to enter into holy orders; and it is presumed, though his education had not been regular, that he found no difficulty in obtaining them. He was ordained by the Bishop of Lincoln, and had a law degree conferred on him.

About the same time he married a lady of Coleshill, named Ensor, "whose grandmother," says he, "was a Shakspeare, descended from a brother of every body's Shakspeare." His ecclesiastical provision was a long time but slender. His first patron, Mr Harper, gave him, in 1741, Calthorpe, in Leicestershire, of L.80 a year, on which he lived ten years; and in April 1751 he exchanged it for Belchford, in Lincolnshire, of L.75, which was given him by Lord Chancellor Hardwicke, on the recommendation of a friend to virtue and the muses. His condition now began to mend. In 1752 Sir John Heathcoate gave him Coningsby, of L.140 a year, and, in 1756, when he was created LL.B. without any solicitation of his own, obtained for him from the chancellor, Kirby-on-Bane, of L.110. In 1757 he published *The Fleece*, his greatest poetical work, of which Dr Johnson relates this ludicrous story. Dodsley the bookseller was one day mentioning it to a critical visitor, with more expectation of success than the other could easily admit. In the conversation the author's age was asked; and being represented as advanced in life, "He will," said the critic, "be buried in woollen." He did not indeed long outlive that publication, nor enjoy the increase of his preferments; for a consumptive disorder, with which he had long struggled, carried him off at length in 1758.

Mr Dyer's character as a writer has been fixed by three poems, *Grongar Hill*, *The Ruins of Rome*, and *The Fleece*; in which a poetical imagination perfectly original, a natural simplicity connected with, and often productive of the true sublime, and the warmest sentiments of benevolence and virtue, have been universally observed and admired. These pieces were published separately in his lifetime; but after his death were collected and published in one volume 8vo, 1761, with a short account of himself prefixed.

DYNAMICS.

Dynamics.
Definition.

1. THIS name marks that department of physico-mathematical science which contains the abstract doctrine of *moving forces;* that is, whatever necessarily results from the relations of our ideas of motion, and of the immediate causes of its production and changes.

Object of dynamics is change of that condition of a thing which we call its *motion.*

2. All *changes* of motion are considered by us as the indications, the characteristics, and the measures of changing causes. This is a physical law of human thought, and therefore a principle to which we may refer, and from which we must derive all our knowledge of those causes. When we appeal to our own thoughts or feelings, we do not find in ourselves any disposition to refer mere existence to any cause, although the beginning of existence certainly produces this reference in an instant. Had we always observed the universe in motion, it does not appear that we should have ascribed it to a cause, till the observation of relative rest, or something leading to it, had enabled us to separate, by abstraction, the notion of matter from that of motion. We might then perceive that rest is not incompatible with matter; and we might even observe, by means of relative motions, that absolute rest might be produced by the concourse of equal and opposite motions. But all this requires reflection and reasoning, whereas we are now speaking of the first suggestions of our minds.

3. We cannot have any notion of motion *in abstracto,* without considering it as a state or condition of existence which would remain if not changed by some cause. It is from changes alone, therefore, that we infer any agency in nature; and it is in these that we are to find all that we know of their causes.

Mechanical relation, what.

4. When we look around us, we cannot but observe that the motions of bodies have in most cases, if not always, some relation to the situation, the distance, and the discriminating qualities of other bodies. The motions of the moon have a palpable relation to the earth; the motions of the tides have as evident a relation to the moon; the motions of a piece of iron have a palpable dependence on a magnet. The vicinity of the one seems to be the occasion at least of the motions of the other. The causes of these motions have an evident connection with or dependence on the other body. We are even disposed to imagine that they are inherent in that body, and that it possesses certain qualities which are the causes of those modifications of motion in other bodies. These serve to distinguish some bodies from others, and may therefore be called *properties;* and since the condition of other bodies so evidently depends on them, these properties express very interesting relations of bodies, and are chiefly attended to in the enumeration of the circumstances which ascertain what we call the *nature* of any thing. We do not mean to say that these inferences are always just; nay, we know that many of them are ill founded; but they are real, and they serve abundantly for informing us what we may expect from any proposed situation of things. It is enough for us to know, that when a piece of iron is so and so situated in relation to a magnet, it will move in a certain manner.

Dyna

This mutual relation of bodies is differently considered, according to the interest that we chance to take in the phenomenon. The cause of the approach of the iron to a magnet is generally ascribed to the magnet, which is said to attract the iron, because we commonly employ the magnet in order that these motions may take place. The similar approach of a stone to the earth is ascribed to the stone, and we say that it tends to the earth. In all probability the procedure of nature is the same in both; for they are observed in every instance to be mutual between the related bodies. As iron approaches a magnet, so the magnet approaches the iron. The same thing is observed in the motions of electrified bodies; also in the case of the stone and the earth. Therefore the cause of the motions may be conceived as inherent in either, or in both.

Force
Action
figurat
terms
used in
chanis

The qualities thus inherent in bodies constituting their mechanical relations, have been called the *mechanical affections of matter.* But they are more commonly named *powers* or *forces;* and the event which indicates their presence is considered as the effect and mark of their agency. The magnet is said to *act* on the iron, the earth is said to *act* on the stone; and the iron and the stone are said to *act* on the magnet and on the earth.

All this is figurative or metaphorical language. All languages have begun with social union, and have improved along with it. The first collections of words expressed the most familiar and the most interesting notions. In the process of social improvement, the number of words did not increase in the same proportion with the notions that became interesting and familiar in their turn: for it often happened that relations of certain ideas so much resembled the relations of certain other ideas, that the word expressing one of them served very well for expressing the other; because the dissimilar circumstances of the two cases prevented all chance of mistake. Thus we are said to *surmount* a difficulty, without attaching to the word the notion of *getting over* a steep hill. Languages are thus filled with figurative expressions.

But th
analog
not in
force,
in the
fect.

5. *Power, Force,* and *Action,* are words which must have appeared in the language of the most simple people; because the notions of personal ability, strength, and exertion, are at once the most familiar and the most interesting that can have a place in the human mind. These terms, when used in their pure, primitive sense, express the notions of the power, force, and action of a sentient, active being. Such a being only is an agent. The exertion of his power or force is (exclusively) action; but the relation of cause and effect so much resembles in its results the relation between this force and the work performed, that the same term may be very intelligibly employed for both. Perhaps the only case of pure unfigurative action is that of the mind on the body. But as this is always with the design of producing some change on external bodies, we think only of them; the instrument or tool is overlooked, and we say that we act on the external body. Our *real* action therefore is but the first movement in a long train of successive events, and is but the remote cause of the interesting event. The resemblance to such actions is very strong indeed in many cases of mechanical phenomena. A man throws a ball by the motion of his arm. A spring impels a ball in the same manner by unbending. These two events resemble each other in every circumstance but the action of the mind on the corporeal organ; the rest of it is a train of pure mechanism. In general, because the ultimate results of the mutual influence of bodies on each other greatly resemble the ultimate results of our actions on bodies, we have not invented appropriated terms, but have contented ourselves with those already employed for expressing our own actions, the exertions of our own powers or forces. The relation of physical cause and effect is expressed metaphorically in the words which belong properly to the relation of agent and action. This has been attended by the usual consequences of poverty

of language, namely, ambiguity, and sometimes mistake, both in our reflections (which are generally carried on by mental discourse), our reasonings, and our conclusions. It is necessary to be on our guard against such mistakes; for they frequently amount to the confounding of things totally different. Many philosophers of great reputation, on no better foundation than this metaphorical language, have confounded the relations of activity and of causation, and even denied that there is any difference; and they have affirmed that there is the same invariable relation between the determinations of the will and the inducements that prompt them, as there is between any physical power and its effect. Others have maintained that the first mover in the mechanical operations, and indeed through the whole train of any complicated event, is a percipient and intending principle, in the same manner as in our actions. According to these philosophers, a particle of gravitating matter perceives its relation to every other particle in the universe, and determines its own motion according to fixed laws, in exact conformity to its situation. But the language, and even the actions of all men, show that they have a notion of the relation of an agent to the action, easily distinguishable (because all distinguish it) from the relation between the physical cause and its effect. This metaphorical language has affected the doctrines of mechanical philosophy, and has produced a dispute about some of its first principles; the only way to decide this dispute is to avoid most scrupulously all metaphorical language, though at the expense of much circumlocution.

Dir ions for t safe emp- me of this a- logy.

6. When we speak of powers or forces as residing in a body, and the effect as produced by their exertion, the body, considered as possessing the power, is said to *act* on the other. A magnet is said to act on a piece of iron; a billiard ball in motion is said to act on one that is hit by it; but if we attempt to fix our attention on this action, as distinct both from the agent and the thing acted on, we find no object of contemplation; the exertion or procedure of nature in producing the effect does not come under our view. When we *speak* of the action as distinct from the agent, we find that it is not the action, properly speaking, but the act, that we speak of. In like manner the action of a mechanical power can be conceived only in the effect produced.

Act imp s cha ; and ere mot is not tion.

7. A man is not said to act unless he produces some effect. Thought is the act of the thinking principle; motion of the limb is the act of the mind on it. In mechanics also, there is action only in so far as there is mechanical effect produced. I must act violently in order to begin motion on a slide. I must exert force, and this force exerted produces motion. I conceive the production of motion in all cases as the exertion of force; but it requires no exertion to continue the motion along the slide; I am conscious of none; therefore I ought to infer that no force is necessary for the continuation of any motion. The continuation of motion is not the production of any new effect, but the permanency of an effect already produced. We indeed consider motion as the effect of an action; but there would be no effect if the body were not moving. Motion is not the action, but the effect of the action.

Pre on, imp ion.

8. Mechanical actions have been usually classed under two heads. They are either *pressures* or *impulsions*. They are generally considered as of different kinds—the exertions of different powers. *Pressure* is supposed to differ essentially from *impulse*.

Instead of attempting to define, or describe, these two kinds of forces and actions, we shall just mention some instances. This will give us all the knowledge of their distinctions that we can acquire.

Examples of pression.

When a ball lies on a table, and I press it gently on one side, it moves toward the other side of the table. If I follow it with my finger, continuing my pressure, it accelerates continually in its motion. In like manner, when I press on the handle of a common kitchen jack, the fly *begins* to move. If I continue to urge or press round the handle, the fly accelerates continually, and may be brought into a state of very rapid motion. These motions are the effects of genuine pressure. The ball would be urged along the table in the same manner, and with a motion continually accelerated, by the unbending of a spring. Also, a spring coiled up round the axis of the handle of the jack would, by uncoiling itself, urge round the fly with a motion accelerating in the same way. The more I reflect on the pressure of my finger on the ball, and compare it with the effect of the spring on it, the more clearly do I see the perfect similarity; and I call these influences, exertions, or actions, by one name, *pressure*, taken from the most familiar instance of them.

Again, the very same motion may be produced in the ball or fly, by pulling the ball or the machine by means of a thread, to which a weight is suspended. As both are motions accelerated in the same manner, I call the influence or action of the thread on the ball or machine by the same name, *pressure*, and *weight* is considered as a pressing power. Indeed I feel the same compression from the real pressure of a man on my shoulders that I would feel from a load laid on them. But the weight in our example is acting by the intervention of the thread. By its pressure it is pulling at that part of the thread to which it is fastened; this part is pulling at the next by means of the force of cohesion; and this pulls at a third, and so on, till the most remote pulls at the ball or the machine. Thus may elasticity, weight, cohesion, and other forces, perform the office of a genuine power; and since their result is always a motion beginning from nothing, and accelerating by perceptible degrees to any velocity, this resemblance makes us call them by one familiar name.

But further, I see that if the thread be cut, the weight will fall with an accelerated motion, which will increase to any degree, if the fall be great enough. I ascribe this also to a pressing power acting on the weight. Nay, after a very little refinement, I consider this power as the cause of the body's weight; which word is but a distinguishing name for this particular instance of pressing power. Gravitation is therefore added to the list of pressures; and for similar reasons the attractions and repulsions of magnets or electric bodies may be added to the list; for they produce actual compressions of bodies placed between them, and they produce motions gradually accelerated, precisely as gravitation does. Therefore all these powers may be distinguished by this descriptive name, *pressures*, which, in strict language, belongs to one of them only.

Gravity, attractions, and repulsions, are considered as pressions.

Several writers, however, subdivide this great class into pressions and solicitations. Gravity is a solicitation *ab extra*, by which a body is urged downward. In like manner the forces of magnetism and electricity, and a vast variety of other attractions and repulsions, are called *solicitations*. We see little use for this distinction, and the term is too like an affection of mind.

Examples of impulsion.

9. *Impulsion* is exhibited when a ball in motion puts another ball into motion by hitting, or (to speak metaphorically) by striking it. The appearances here are very different. The body that is struck acquires, in the instant of impulse, a sensible quantity of motion, and sometimes a very rapid motion. This motion is neither accelerated nor retarded after the stroke, unless it be affected by some other force. It is also remarked that the rapidity of the motion depends, *inter alia*, on the previous velocity of the striking body. For instance, if a clay ball,

moving with any velocity, strike another equal ball which is at rest, the struck ball moves with half the velocity of the other. And it is farther remarkable that the striking body always loses as much motion as the struck body gains. This universal and remarkable fact seems to have given rise to a confused or indistinct notion of a sort of transference of motion from one body to another. The phraseology in general use on this subject expresses this in the most precise terms. The one ball is not said to cause or produce motion in the other, but to *communicate* motion to it; and the whole phenomenon is called the *communication of motion.* We call this an *indistinct* notion; for surely no one will say that he has any clear conception of it. We can form the most distinct notion of the communication of heat, or of the cause of heat; of the communication of saltness, sweetness, and a thousand other *things;* but we cannot conceive how part of that identical motion which was formerly in A, is now infused into B, being given up by A. It is in our attempt to form this notion that we find that motion is not a *thing,* not a substance which can exist independently, and is susceptible of actual transference. It appears in this case to be a state, or condition, or mode of existence, of which bodies are susceptible, which is producible, or (to speak without metaphor) causable, in bodies, and which is the effect and *characteristic* of *certain* natural qualities, properties, or powers. We are anxious to have our readers impressed with clear and precise notions on this subject, being confident that such, and only such, will carry them through some intricate paths of mechanical and philosophical research.

Communication of motion not a good expression.

Inherent force is the distinctive character of impulsion,

10. The remarkable circumstance in this phenomenon is, that a rapid motion, which requires for the effecting it the action of a pressing power, continued for a sensible, and frequently a long time, seems to be affected in an instant by impulsion. This has tended much to support the notion of the actual transference of something formerly possessed exclusively by the striking body, inhering in it, but separable, and now transfused into the body stricken. And now room is found for the employment of metaphor, both in thought and language. The *striking* body affects the body which it thus impels: it therefore possesses the *power* of impulsion, that is, of *communicating* motion. It possesses it only while it is in motion. This *power,* therefore, is the efficient distinguishing cause of its motion, and its only office must be the continuation of this motion. It is therefore called the *inherent force,* the force inherent in a moving body, VIS INSITA *corpori moto.* This force is transfused into the body impelled; and *therefore* the transference is instantaneous, and the impelled body continues its motion till it is changed by some other action. All this is at first sight very plausible; but a scrupulous attention to those feelings which have given rise to this metaphorical conception should have produced very different notions. I am conscious of exertion in order to begin motion on a slide; but if the ice be very smooth, I am conscious of no exertion in order to slide along. My power is felt only while I am conscious of exerting it; therefore I have no primitive feeling or notion of power while I am sliding along. I am certain that no exertion of power is necessary here. Nay, I find that I cannot think of my moving forward without effort otherwise than as a certain mode of my existence. Yet we imagine that the partizans of this opinion did really deduce it in some shape from their feelings. We must continue the *exertion* of walking in order to walk on; our power of walking must be continually exerted, otherwise we shall stop. But this is a very imperfect, incomplete, and careless observation. Walking is much more than mere continuance in progressive motion. It is a continually repeated lifting our body up a small height, and allowing it to come down again. This renewed ascent requires repeated exertion.

11. We have other observations of importance yet to make on this force of moving bodies, but this is not the most proper occasion. Meanwhile we must remark, that the instantaneous production of rapid motion by impulse has induced the first mechanicians of Europe to maintain that the power or force of impulse is unsusceptible of any comparison with a pressing power. They have asserted that impulse is infinitely great when compared with pressure; not recollecting that they held them to be things totally disparate, that have no proportion more than weight and sweetness. But these gentlemen are perpetually enticed away from their creed by the similarity of the ultimate results of pressure and impulse. No person can find any difference between the motion of two balls moving equally swift, in the same direction, one of which is descending by gravity, and the other has derived its motion from a blow. This struggle of the mind to maintain its faith, and yet accommodate its doctrines to what we see, has occasioned some other curious forms of expression. Pressure is considered as an *effort* to produce motion. When a ball lies on a table, its weight, which they call a *power,* continually and repeatedly *endeavours* (mark the metaphorical word and thought) to move the ball downward. But these efforts are ineffectual. They say that this ineffectual power is *dead,* and call it a *vis mortua:* but the force of impulsion is called a *vis viva,* a living force. But this is very whimsical and very inaccurate. If the impelling ball falls perpendicularly on the other lying on the table, it will produce no motion, any more than gravity will; and if the table be annihilated, gravity becomes a *vis viva.*

We must now add, that in order to prove that impulse is infinitely greater than pressure, these mechanicians turn our attention to many familiar facts which plead strongly in their favour. A carpenter will drive a nail into a board with a very moderate blow of his hammer. This will require a pressure which seems many hundred times greater than the impelling effort of the carpenter. A very moderate blow will shiver into pieces a diamond which would carry the weight of a mountain. Seeing this prodigious superiority in the impulse, how shall they account for the production of motion by means of pressure; for this motion of the hammer might have been acquired by its falling from a height; nay, it is actually acquired by means of the continued pressure of the carpenter's arm. They consider it as the aggregate of an infinity of succeeding pressures in *every* instant of its continuance; so that the insignificant smallness of each effort is compensated by their inconceivable number.

On the whole, we do not think that there is clear evidence that there are two kinds of mechanical force essentially different in their nature. It is virtually given up by those who say that impulse is infinitely greater than pressure. Nor is there any considerable advantage to be obtained by arranging the phenomenon under those two heads. We may perhaps find some method of explaining satisfactorily the remarkable difference that is really observed in the two modes of producing motion; namely, the gradual production of motion by acknowledged pressure, and the instantaneous production of it by impulse. Indeed we should not have taken up so much of our readers' attention with this subject, had it not been for some inferences that have been made from these premises, which meet us in our very entry on the consideration of first principles, and that are of extensive influence on the whole science of mechanical philosophy, and, indeed, on the whole study of nature.

Is Imp- ion t ole c se of mo n?

12. Mechanicians are greatly divided in their opinion about the nature of the sole moving force in nature. Those whom we are now speaking of seem to think that all motion is produced by pressure; for when they consider impulse as equivalent to the aggregate of an infinity of repeated pressures, they undoubtedly suppose any pressure, however insignificant, as a moving force. But there is a party, both numerous and respectable, who maintain that impulsion is the sole cause of motion. We see bodies in motion, say they, and we see them impel others; and we see that this production of motion is regulated by such laws, that there is but one absolute quantity of motion in the universe which remains unalterably the same. It must therefore be transfused in the acts of collision. We also see, with clear evidence, in some cases, that motion can produce pressure. Euler adduces some very whimsical and complicated cases, in which an action precisely similar to pressure may be produced by motion. Thus, two balls connected by a thread may be so struck that they shall move forward, and at the same time wheel round. In this case the connecting thread will be stretched between them. Now, say the philosophers, since we see motion, and see that pressure may be produced by motion, it is preposterous to imagine that it is any thing else than a result of certain motions; and it is the business of a philosopher to inquire and discover what motions produce the pressures that we observe.

They then proceed to account for those pressing powers, or solicitations to motion, which we observe in the acceleration of falling bodies, the attractions of magnetism and electricity, and many other phenomena of this kind, where bodies are put in motion by the vicinity of other bodies, or, in the popular language, by the action of other bodies at a distance. To say that a magnet can act on a piece of remote iron, is to say that it can act *where* it is not, which is as absurd as to say that it can act *when* it is not. *Nihil movetur*, says Euler, *nisi a contiguo et moto.*

How oes it pr uce pres e?

The bulk of these philosophers are not very anxious about the way in which these motions are produced, nor do they fall upon such ingenious methods of producing pressure as the one already mentioned, which was adduced by Euler. The piece of iron, say they, is put in motion when brought into the neighbourhood of a magnet, because there is a stream of fluid issuing from one pole of the magnet, which circles round the magnet, and enters at the other pole. This stream impels the iron, and arranges it in certain determined positions, just as a stream of water would arrange the flote grass. In the same manner, there is a stream of fluid continually moving towards the centre of the earth, which impels all bodies in lines perpendicular to the surface; and so on with regard to other like phenomena. These motions are thus reduced to very simple cases by impulsion.

Inco a- tible ith the es of phil . phis .

It is unnecessary to refute this doctrine at present: it is enough that it is contrary to all the dictates of common sense. To *suppose* an agent that we do not see, and for whose existence we have not the smallest argument; with equal propriety we might suppose ministering spirits, or any thing that we please.

Oth mai in that es- sure the sole ov- ing ce.

13. Other philosophers are so dissatisfied with this notion of the production of pressure, that they, on the other hand, affirm that pressure is the only moving force in nature; not according to the popular notion of pressure, by the mutual contact of solid bodies, but that kind of pressure which has been called *solicitation*, such as the power of gravity. They affirm that there is no such thing as contact on instantaneous communication of motion by real collision. They say, and they prove it by very convincing facts, that the particles of solid bodies exert very strong repulsions to a small distance; and therefore, when they are brought by motion sufficiently near to another body, they repel it, and are equally repelled by it. Thus is motion produced in the other body, and their own motion is diminished. And they then show, by a scrupulous consideration of the state of the bodies while the one is advancing and the other retiring, in what manner the two bodies attain a common velocity, so that the quantity of motion before collision remains unchanged, the one body gaining as much as the other loses. They also show cases of such mutual action between bodies, where it is evident that they have never come into contact; and yet the result has been precisely similar to those cases where the motion appeared to be changed in an instant. Therefore they conclude that there is no such thing as instantaneous *communication*, or transfusion of motion, by contact in collision or impulse. The reason why previous motion of the impelling body is necessary, is not that it may have a *vis insita corpori moto*, a force inherent in it *by its being in motion*, but that it may continue to follow the impelled and retiring body, and exert on it a force inherent in itself, whether in motion or at rest. According to these philosophers, therefore, all moving forces are of that kind which has been named *solicitation*, such as gravity. We shall know it afterwards by the more familiar and descriptive name of *accelerating* or *retarding* force.

Action, re-sistance, re-action.

14. The exertions of mechanical forces are differently termed, according to the reference that we make to the result. If in boxing or wrestling I strike, or endeavour to throw my antagonist, I am said to *act;* but if I only parry his blows, or prevent him from throwing me, I am said to *resist.* This distinction is applied to the exertions of mechanical powers. When one body, A, changes the motion of another, B, we may consider the change in the motion of B either as the indication and measure of A's power of producing motion, or as the indication and measure of A's resistance to the being brought to rest, or having its motion any how changed. The distinction is not in the thing itself, but only in the reference that we are disposed, by other considerations, to make of its effect. They may be distinguished in the following manner: If a change of motion follow when one of the powers ceases to be exerted, that power is conceived as having resisted. The whole language on this subject is metaphorical. Resistance, effort, endeavour, &c. are words which cannot be employed in mechanical discussions without figure, because they all express notions which relate to sentient beings; and the unguarded indulgence of this figurative language has so much affected the imagination of philosophers, that many have almost animated all matter. Perhaps the word *reaction*, introduced by Newton, is the best term for expressing that mutual force which is perceived in all the operations of nature that we have investigated with success. As the magnet attracts iron, and in so doing is said to *act* on it; so the iron attracts the magnet, and may be said to *re-act* on it.

We need not suppose action at a distance. Tendency.

15. With respect to the difficulty that has been objected to the opinion of those who maintain that all the mechanical phenomena are produced by the agency of attracting or repelling forces; namely, that this supposes the bodies to act on each other at a distance, however small those distances may be, which is thought to be absurd, we may observe, that we may ascribe the mutual approaches or recesses to tendencies to or from each other. What we call *the attraction of the magnet* may be considered as a tendency of the iron to the magnet, somewhat similar to the gravitation of a stone toward the earth. We surely (at least the unlearned) can and do conceive the iron to be affected by the magnet, *without thinking* of any intermedium. The thing is not therefore inconceivable, which is all that we know about absurdity; and we do not

know any thing about the nature or essence of matter which renders this tendency to the magnet impossible. That we do not see intuitively any reason why the iron should approach the magnet, must be granted; but this is not enough to entitle us to say that such a thing is impossible, or inconsistent with the nature of matter. It appears, therefore, to be very hasty and unwarrantable to suppose the impulse of an invisible fluid, of which we know nothing, and of the existence of which we have no proof. Nay, if it be true that bodies do not come into contact, even when one ball hits another, and drives it before it, this invisible fluid will not solve the difficulty, because the same difficulty occurs in the action of any particle of the fluid on the body. We are obliged to say that the production of motion without any *observed* contact, is a much more familiar phenomenon than the production of motion by impulsion. More motion has been produced in this way by the gravitation of a small stream of water, running ever since the creation, than by all the impulses in the world twice told. We do not mean by this to say, that the giving to this observed mutual relation between iron and a loadstone the name *tendency* makes it less absurd than when we say that the loadstone attracts the iron; it only makes it more conceivable. It suggests a very familiar analogy; but both are equally figurative expressions, at least as the word tendency is used at present. In the language of ancient Rome, there was no metaphor when Virgil's hero said, *Tendimus in Latium. Tendere versus solem* means, in plain Latin, to *approach the sun.* The safe way of conceiving the whole is to say that the condition of the iron depends on the vicinity of the magnet.

Attraction, repulsion, are figurative terms.

16. When the exertions of a mechanical power are observed to be always directed toward a body, that body is said to attract; but when the other body always moves off from it, it is said to repel. These also are metaphorical expressions. I attract a boat when I pull it toward me by a rope; this is purely *Attraction:* and it is pure, unfigurative *Repulsion,* when I push any body from me. The same words are applied to the mechanical phenomena, merely because they resemble the results of real attraction or repulsion. We must be much on our guard to avoid metaphor in our conceptions, and never allow those words to suggest to our mind any opinion about the *manner* in which the mechanical forces produce their effects. It is plain, that if the opinion of those who maintain the existence and action of the above-mentioned invisible fluid be just, there is nothing like attraction or repulsion in the universe. We must always recur to the simple phenomenon, the motion to or from the attracting or repelling body; for this is all we see, and generally all that we know.

Forces are conceived as measurable quantities.

17. We conceive one man to have twice the strength of another man, when we see that he can withstand the united effort of two others. Thus animal force is conceived as a quantity, made up of and measured by its own parts. But we doubt exceedingly whether this be an accurate conception. We have not a distinct notion of one strain added to another, though we have of their being joined or combined. We want words to express the difference of these two notions in our own minds, but we imagine that others perceive the same difference. We conceive clearly the addition of two lines or of two minutes; we can conceive them apart, and perceive their boundaries, common to both, where one ends and the other begins. We cannot conceive thus of two forces combined; yet we cannot say that two equal forces are *not* double of one of them. We measure them by the effects which they are known to produce. Yet there are not wanting many cases where the action of two men, equally strong, does not produce a double motion.

How sured.

In like manner, we conceive all mechanical forces as measurable by their effects; and thus they are made the subjects of mathematical discussion. We talk of the proportions of gravity, magnetism, electricity, &c.; nay, we talk of the proportion of gravity to magnetism: yet these, considered in themselves, are disparate, and do not admit of any proportion; but they produce effects, some of which are measurable, and whose assumed measures are susceptible of comparison, being quantities of the same kind. Thus, one of the effects of gravity is the acceleration of motion in a falling body: magnetism will also accelerate the motion of a piece of iron; these two accelerations are comparable. But we cannot compare magnetism with heat, because we do not know any measurable effects of magnetism that are of the same kind with any effects of heat.

By th effects

When we say that the gravitation of the moon is the 3600th part of the gravitation at the sea-shore, we mean that the fall of a stone in a second is 3600 times greater than the fall of the moon in the same time. But we also mean (and this expresses the proportion of the *tendency* of gravitation more purely), that if a stone, when hung on a spring steelyard, draw out the rod of the steelyard to the mark 3600, the same stone, taken up to the distance of the moon, will draw it out no farther than the mark 1. We also mean, that if the stone at the sea-shore draw out the rod to any mark, it will require 3600 such stones to draw it out to that mark when the trial is made at the distance of the moon. It is not, therefore, in consequence of any immediate perception of the proportion of the gravitation at the moon to that at the surface of the earth that we make such an assertion; but these motions, which we consider as its effects in these situations, being magnitudes of the same kind, are susceptible of comparison, and have a proportion which can be ascertained by observation. It is these proportions that we contemplate; although we speak of the proportions of the unseen causes, the forces, or endeavours to descend. It will be of material service to the reader to peruse the judicious and acute dissertation on *quantity* in the works of Dr Reid (vol. ii.), where he will see clearly how force, velocity, density, and many other magnitudes of very frequent occurrence in mechanical philosophy, may be made the subjects of mathematical discussion, by means of some of those proper quantities, measurable by their own parts, which are to be assumed as their measures. Pressures are measurable only by pressures. When we consider them as moving powers, we should be able to measure them by *any* moving powers, otherwise we cannot compare them; therefore it is not as pressures that we then measure them. This observation is momentous.

One circumstance must be carefully attended to. That those assumed measures may be accurate, they must be invariably connected with the magnitudes which they are employed to measure, and so connected that the degrees of the one must change in the same manner with the degrees of the other. This is evident, and is granted by all. But we must also *know* this of the measure we employ; we must see this constant and precise relation. How can we know this? We do not perceive force as a separate existence, so as to see its proportions, and to see that these are the same with the proportions of the measures, in the same manner that Euclid sees the proportions of triangles and those of their bases, and that these proportions are the same when the triangles are of equal altitudes. How do we discover that to every magnitude which we call *force* is invariably attached a corresponding magnitude of acceleration or deflection? Clearly. In fact, the very existence of the force is an inference that we make from the observed acceleration; and the degree of the force is, in like manner, an inference from the observed magnitude of the acceleration. Our measures are therefore necessarily connected with the magnitudes which they measure, and their proportions are the same; because the one is always an inference from the other, both in species and in degree.

Dynamics is a demonstrative science.

18. It is now evident that these disquisitions are susceptible of mathematical accuracy. Having selected our measures, and observed certain mathematical relations of those measures, every inference that we can draw from the mathematical relations of the proportions of those representations is true of the proportions of the motions, and therefore of the proportions of the forces. And thus dynamics becomes a demonstrative science, one of the *disciplinæ accuratæ*.

19. But moving forces are considered as differing and in kind; that is, in direction. We assign to the force the direction of the observed change of motion, which is not only the indication, but also the characteristic, of the changing force. We call it an *accelerating*, *retarding*, *deflecting force*, according as we observe the motion to be accelerated, retarded, or deflected.

These denominations show us incontestably that we have no knowledge of the forces different from our knowledge of the effects. The denominations are all either descriptive of the effects, as when we call them accelerating, penetrating, protrusive, attractive, or repulsive forces; or they are names of reference to the substances in which the accelerating, protrusive, &c. forces are supposed to be inherent, as when we call them *magnetism*, *electricity*, *corpuscular*, &c.

Forces are discovered by their opposition to other forces.

20. When I struggle with another, and feel, that in order to prevent being thrown, I must exert force, I learn that my antagonist is exerting force. This motion is transferred to matter; and when a moving power which is *known* to operate produces no motion, we conceive it to be opposed by another equal force, the existence, agency, and intensity of which is detected and measured by these means. The quiescent state of the body is considered as a change on the state of things that would have been exhibited in consequence of the known action of one power, had this other power not acted; and this change is considered as the indication, characteristic, and measure, of another power, detected in this way. Thus forces are recognised not only by the changes of motion which they produce, but also by the changes of motion which they prevent. The cohesion of matter in a string is inferred not only by its giving motion to a ball which I pull toward me by its intervention, but also by its suspending that ball, and hindering it from falling. I know that gravity is acting on the ball, which, however, does not fall. The solidity of a board is equally inferred from its stopping the ball which strikes it, and from the motion of the ball which it drives before it. In this way we learn that the particles of tangible matter cohere by means of moving forces, and that they resist compression with force; and in making this inference, we find that this corpuscular force exerted between the particles is mutual, opposite, and equal; for we must apply force equally to *a* or to *b*, in order to produce a separation or a compression. We learn their equality, by observing that no motion ensues while these mutual forces are known to act on the particles; that is, each is opposed by another force, which is neither inferior nor superior to it.

OF THE LAWS OF MOTION.

Such, then, being our notions of mechanical forces, the causes of the sensible changes of motion, there will result certain consequences from them, which may be called axioms or laws of motion. Some of these may be intuitive, offering themselves to the mind as soon as the notions which they involve are presented to it. Others may be as necessary results from the relations of these notions, but may not readily offer themselves without the mediation of axioms of the first class. We shall select those which are intuitive, and may be taken for the first principles of all discussions in mechanical philosophy.

First Law of Motion.

FIRST LAW OF MOTION.

Every body continues in a state of rest, or of uniform rectilineal motion, unless affected by some mechanical force.

21. This is a proposition, on the truth of which the whole science of mechanical philosophy ultimately depends. It is therefore to be established on the firmest foundation; and a solicitude on this head is the more justifiable, because the opinions of philosophers have been extremely different, both with respect to the truth of this law, and with respect to the foundation on which it is built. These opinions are, in general, very obscure and unsatisfactory; and, as is natural, they influence the discussions of those by whom they are held through the whole science. Although of contradictory opinions one only can be just, and it may appear sufficient that this one be established and uniformly applied; yet a short exposition, at least, of the rest is necessary, that the greatest part of the writings of the philosophers may be intelligible, and that we may avail ourselves of much valuable information contained in them, by being able to perceive the truth in the midst of their imperfect or erroneous conceptions of it.

Does continued motion indicate continued action?

22. It is not only the popular opinion that rest is the natural state of body, and that motion is something foreign to it, but it has been seriously maintained by the greatest part of those who are esteemed philosophers. They readily grant that matter will continue at rest unless some moving force act upon it. Nothing seems necessary for matter's remaining where it is, but its continuing to exist. But it is far otherwise, say they, with respect to matter in motion. Here the body is continually changing its relations to other things; therefore the continual agency of a changing cause is necessary (by the fundamental principle of all philosophical discussion), for there is here the continual production of an effect. They say that this metaphysical argument receives complete confirmation (if confirmation of an intuitive truth be necessary) from the most familiar observation. We see that all motions, however violent, terminate in rest; and that the continual exertion of some force is necessary for their continuance.

Whimsical notion of elemental minds.

23. These philosophers therefore assert, that the continual action of the moving cause is *essentially* necessary for the continuance of the motion; but they differ among themselves in their notions and opinions about this cause. Some maintain that all the motions in the universe are produced and continued by the immediate agency of Deity; others affirm, that in every particle of matter there is inherent a sort of mind, the φυσις and ὁσπερψυχη of Aristotle, which they call an *Elemental Mind*, which is the cause of *all* its motions and changes. An overweening reverence for Greek learning has had a great influence in reviving this doctrine of Aristotle. The Greek and Roman languages are affirmed to be more accurate expressions of human thought than the modern languages are. In those ancient languages, the verbs which express motion are employed both in the active and passive voice; whereas we have only the active verb *to move*, for expressing both the state of motion and the act of putting in motion. "The stone *moves* down the slope, and *moves* all the pebbles which lie in its way;" but in the ancient lan-

First Law of Motion.

guages, the mere state of motion is always expressed by the passive or middle voice. The accurate conception of the speakers is therefore extolled. The state of motion is expressed as it ought to be, as the result of a continual action. Κινειται, *movetur*, is equivalent to "it is moved." According to these philosophers, every thing which *moves* is mind, and every thing that *is moved* is body.

The argument is futile, and it is false; for the modern languages are, in general, equally accurate in this instance: "*se mouvoir*," in French; "*fich bewegen*," in German; "*dvigatsu*," in Slavonic; are all passive or reflected. And the ancients said that "rain falls, water runs, smoke rises," just as we do. The ingenious author of *Ancient Metaphysics* has taken much pains to give us, at length, the procedures of those elementary minds in producing the ostensible phenomena of local motion; but it seems to be merely an abuse of language, and a very frivolous abuse. This elemental mind is known and characterised only by the effect which we ascribe to its action; that is, by the motions or changes of motions. Uniform and unexcepted experience shows us that these are regulated by laws as precise as those of mathematical truth. We consider nothing as more fixed and determined than the common laws of mechanism. There is nothing here that indicates any thing like spontaneity, intention, purpose; none of those marks by which mind was first brought into view; but they are very like the effects which we produce by the exertions of our corporeal forces; and we have accordingly given the name *force* to the causes of motion. It is surely much more apposite than the name mind, and conveys with much more readiness and perspicuity the very notions that we wish to convey.

Action not necessary for the continuance of motion.

24. We now wish to know what reason we have to think that the continual action of some cause is necessary for continuing matter in motion, or for thinking that rest is its natural state. If we pretend to draw any argument from the nature of matter, that matter must be known, as far as is necessary for being the foundation of argument. Its very existence is known only from observation; all our knowledge of it must therefore be derived from the same source.

If we take this way to come at the origin of this opinion, we shall find that experience gives us no authority for saying that rest is the natural condition of matter. We cannot say that we have ever seen a body at rest; this is evident to every person who allows the validity of the Newtonian philosophy, and the truth of the Copernican system of the sun and planets; all the parts of this system are in motion. Nay, it appears from many observations, that the sun, with his attending planets, is carried in a certain direction, with a velocity which is very great. We have no unquestionable authority for saying that any one of the stars is absolutely fixed; but we are *certain* that many of them are in motion. Rest is therefore so rare a condition of body, that we cannot say, from any experience, that it is its natural state.

25. It is easy, however, to see that it is from observation that this opinion has been derived; but the observation has been limited and careless. Our experiments in this sublunary world do indeed always require continued action of some moving force to continue the motion; and if this be not employed, we see the motions slacken every minute, and terminate in rest after no long period. Our first notions of sublunary bodies are indicated by their operation in cases where we have some interest. Perpetually seeing our own exertions necessary, we are led to consider matter as something not only naturally quiescent and inert, but sluggish, averse from motion, and prone to rest (we must be pardoned this metaphorical language, because we can find no other term). What is expressed by it, on this occasion, is precisely one of the erroneous or inadequate conceptions that are suggested to our thoughts by reason of the poverty of language. We animate matter in order to give it motion, and then we endow it with a sort of moral character in order to explain the appearance of those motions.

Firs Law of M ion.

26. But more extended observation has made men gradually desert their first opinions, and at last allow that matter has no peculiar aptitude to rest. All the retardations that we *observe* have been discovered, one after another, to have a distinct reference to some external circumstances. The diminution of motion is always observed to be accompanied by the removal of obstacles, as when a ball moves through sand, or water, or air; or it is owing to opposite motions which are destroyed; to roughness of the path, or to friction, &c. We find that the more we can keep these things out of the way, the less are the motions diminished. A pendulum will vibrate but a short while in water; much longer in air; and in the exhausted receiver it will vibrate a whole day. We know that we cannot remove *all* obstacles; but we are led by such observations to conclude that, if they *could be completely removed*, our motions would continue for ever. And this conclusion is almost demonstrated by the motions of the heavenly bodies, to which we know of no obstacles, and which we really observe to retain their motions for many thousand years, without the smallest sensible diminution.

Inact y of ma r denie y Leibn .

27. Another set of philosophers maintain an opinion directly opposite to that of the inactivity of matter, and assert, that it is essentially active, and continually changing its state. Faint traces of this are to be found in the writings of Plato, Aristotle, and their commentators. Mr Leibnitz is the person who has treated this question most systematically and fully. He supposes every particle of matter to have a principle of individuality, which he therefore calls a *Monad*. This monad has a sort of *perception* of its situation in the universe, and of its relation to every other part of this universe. Lastly, he says that the monad acts on the material particle much in the same way that the soul of man acts on his body. It modifies the motion of the material atom (in conformity, however, to unalterable laws), producing all those modifications of motion that we observe. Matter, therefore, or at least particles of matter, are continually active, and continually changing their situation.

Mona what.

This o nion il founde

It is quite unnecessary to enter on a formal confutation of Mr Leibnitz's system of monads, which differs very little from the system of elemental minds, and is equally whimsical and frivolous; because it only makes the unlearned reader stare, without giving him any information. Should it even be granted, it would not, any more than the action of animals, invalidate the general proposition which we are endeavouring to establish as the fundamental law of motion. Those powers of the monads, or of the elemental minds, are the causes of all the changes of motion; but the mere material particle is subject to the law, and requires the exertion of the monad in order to exhibit a change of motion.

28. A third sect of philosophers, at the head of which we may place Sir Isaac Newton, maintain the doctrine enounced in the proposition. But they differ much in respect of the foundation on which it is built.

Some losophe deduce s law of tion fr the wa of a de *mining* cause.

Some assert that this truth flows from the nature of the thing. If a body be at rest, and you assert that it will not remain at rest, it must move in some one direction. If it be in motion in any direction, and with any velocity, and do not continue its equable, rectilineal motion, it must either be accelerated or retarded; it must turn either to one side or to some other side. The event, whatever it be, is individual and determinate; but no cause which

t Law
otion.

can determine it is supposed; therefore the determination cannot take place, and no change will happen in the condition of the body with respect to motion. It will continue at rest, or persevere in its rectilineal and equable motion.

But considerable objections may be made to this argument of *sufficient reason*, as it is called. In the immensity and perfect uniformity of space and time, there is no determining cause why the visible universe should exist in the place in which we see it rather than in another, or at this time rather than at another. Nay, the argument seems to beg the question. A cause of determination is required as essentially necessary—a determination may be without a cause, as well as a motion without a cause.

O ers de-
du it
fr ex-
pe ence.

29. Other philosophers, who maintain this doctrine, consider it merely as an experimental truth; and proofs of its universality are innumerable.

When a stone is thrown from the hand, we press it forward while in the hand, and let it go when the hand has acquired the greatest rapidity of motion that we can give it. The stone continues in that state of motion which it acquired gradually along with the hand. We can throw a stone much farther by means of a sling, because, by a very moderate motion of the hand, we can whirl the stone round till it acquire a very great velocity, and then we let go one of the strings, and the stone escapes, *by continuing* its rapid motion. We see it still more distinctly in shooting an arrow from a bow. The string presses hard on the notch of the arrow, and it yields to this pressure and goes forward. The string alone would go faster forward. It therefore *continues* to press the arrow forward, and accelerates its motion. This goes on till the bow is as much unbent as the string will allow. But the string is now a straight line. It came into this position with an accelerated motion, and it therefore goes a little beyond this position, but with a retarded motion, being checked by the bow. But there is nothing to check the arrow, therefore the arrow quits the string and flies away.

These are simple cases of perseverance in a state of motion, where the procedure of nature is so easily traced that we perceive it almost intuitively. It is no less clear in other phenomena which are more complicated; but it requires a little reflection to trace the process. We have often seen an equestrian showman ride a horse at a gallop, standing on the saddle, and stepping from it to the back of another horse that gallops alongside at the same rate; and he does this seemingly with as much ease as if the horses were standing still. The man has the same velocity with the horse that gallops under him, and keeps this velocity while he steps to the back of the other. If that other were standing still, the man would fly over his head. And if a man should step from the back of a horse that is standing still, to the back of another that gallops past him, he would be left behind. In the same manner, a slack-wire dancer tosses oranges from hand to hand while the wire is in full swing. The orange, swinging along with the hand, retains the velocity; and when in the air, follows the hand, and falls into it when it is in the opposite extremity of its swing. A ball dropped from the mast-head of a ship that is sailing briskly forward, falls at the foot of the mast. It retains the motion which it had while in the hand of the person who dropped it, and follows the mast during the whole of its fall.

First Law
of Motion.

We also have familiar instances of the perseverance of a body in a state of rest. When a vessel filled with water is drawn suddenly along the floor, the water dashes over the posterior side of the vessel. It is left behind. In the same manner, when a coach or boat is dragged forward, the persons in it find themselves strike against the hinder part of the carriage or boat. Properly speaking, it is the carriage that strikes on them. In like manner, if we lay a card on the tip of the finger, and a piece of money on the card, we may nick away the card, by hitting it neatly on its edge; but the piece of money will be left behind, lying on the tip of the finger. A ball will go through a wall and fly onward; but the wall is left behind. Buildings are thrown down by earthquakes; sometimes by being tossed from their foundations, but more generally by the ground on which they stand being hastily drawn sidewise from under them, &c.

Common
experience
insufficient.

30. But common experience seems insufficient for establishing this fundamental proposition of mechanical philosophy. We must, on the faith of the Copernican system, grant that we never saw a body at rest, or in uniform rectilineal motion; yet this seems absolutely necessary before we can say that we have established this proposition experimentally.

What we imagine, in our experiments, to be putting a body, formerly at rest, into motion, is, in fact, only changing a most rapid motion, not less, and probably much greater, than 90,000 feet per second. Suppose a cannon pointed east, and the bullet discharged at noon day with sixty times greater velocity than we have ever been able to give it: it would appear to set out with this unmeasurable velocity to the eastward, to be gradually retarded by the resistance of the air, and at last brought to rest by hitting the ground. But, by reason of the earth's motion round the sun, the fact is quite the reverse. Immediately before the discharge, the ball was moving to the westward with the velocity of 90,000 feet per second nearly. By the explosion of the powder, and its pressure on the ball, some of this motion is destroyed, and at the muzzle of the gun the ball is moving slower, and the cannon is hurried away from it to the westward. The air, which is also moving to the westward 90,000 feet in a second, gradually communicates motion to the ball, in the same manner as a hurricane would do. At last (the ball dropping all the while) some part of the ground hits the ball, and carries it along with it.

Other observations must therefore be resorted to, in order to obtain an experimental proof of this proposition; and such are to be found. Although we cannot measure the absolute motions of bodies, we can observe and measure accurately their relative motions, which are the differences of their absolute motions. Now, if we can show experimentally that bodies show equal tendencies to resist the augmentation and the diminution of their relative motions, they, *ipso facto*, show equal tendencies to resist the augmentation or diminution of their absolute motions. Therefore let two bodies, A and B, be put into such a situation that they cannot (by reason of their impenetrability, or the action of their mutual powers) persevere in their relative motions. The change produced on A is the effect and the measure of B's tendency to persevere in its former state; and therefore the proportion of these changes will show the proportion of their tendencies to maintain their former states. Therefore let the following experiment be made at noon.

Experi-
ments pro-
per for the
purpose.

Let A, apparently moving westward three feet per second, hit the equal body B apparently at rest. Suppose, 1*st*, that A impels B forward without any diminution of its own velocity. This result would show that B manifests no tendency to maintain its motion unchanged, but that A retains its motion undiminished.

2*dly*, Suppose that A stops, and that B remains at rest. This would show that A does not resist a diminution of motion, but that B retains its motion unaugmented.

3*dly*, Suppose that both move westward with the velocity of one foot per second. The change on A is a diminution of velocity, amounting to two feet per second.

First Law of Motion.

This is the effect and the measure of B's tendency to maintain its velocity unaugmented. The change on B is an augmentation of one foot per second made on its velocity; and this is the measure of A's tendency to maintain its velocity undiminished. This tendency is but half of the former; and this result would show that the resistance to a diminution of velocity is but half of the resistance to augmentation. It is perhaps but one quarter, for the change on B has produced a double change on A.

4thly, Suppose that both move westward at the rate of one and a half foot per second. It is evident that their tendencies to maintain their states unchanged are now equal.

5thly, Suppose A = 2 B, and that both move, after the collision, two feet per second; B has received an addition of two feet per second to its former velocity. This is the effect and the measure of A's whole tendency to retain its motion undiminished. Half of this change on B measures the persevering tendency of the half of A; but A, which formerly moved with the apparent or relative velocity three, now moves (by the supposition) with the velocity two, having lost a velocity of one foot per second. Each half of A therefore has lost this velocity, and the whole loss of motion is two. Now this is the measure of B's tendency to maintain its former state unaugmented; and this is the same with the measure of A's tendency to maintain its own former state undiminished. The conclusion from such a result would therefore be, that bodies have equal tendencies to maintain their former states of motion without augmentation and without diminution.

What is supposed in the fourth and fifth cases is really the result of all the experiments which have been tried; and this law regulates all the changes of motion which are produced by the mutual actions of bodies in impulsions. This assertion is true without exception or qualification. Therefore it appears that bodies have no preferable tendency to rest, and that no fact can be adduced which should make us suppose that a motion once begun should suffer any diminution without the action of a changing cause.

But experience is not the proper foundation of an axiom.

But we must now observe, that this way of establishing the first law of motion is very imperfect, and altogether unfit for rendering it the fundamental principle of a whole and extensive science. It is subject to all the inaccuracy that is to be found in our best experiments; and it cannot be applied to cases where scrupulous accuracy is wanted, and where no experiment can be made.

Let us therefore examine the proposition by means of principles which contain the foundation of all our knowledge of active nature. These will, we imagine, give a decision of this question that is speedy and accurate; showing the proposition to be an axiom or intuitive consequence of the relations of those ideas which we have of motion, and of the causes of its production and changes.

Logical proof.

31. It has been fully demonstrated that the powers or forces of which we speak so much are never the immediate objects of our perception. Their very existence, their kind, and their degree, are instinctive inferences from the motions which we observe and class. It evidently follows from this experimental and universal truth, 1*st*, that where no change of motion is observed, no such inference is made, that is, no power is *supposed* to act. But whenever any change of motion is observed, the inference is made; that is, a power or force is supposed to have acted.

In the same form of logical conclusion, we must say that, 2*dly*, when no change of motion is *supposed* or thought of, no force is *supposed;* and that whenever we *suppose* a change of motion, we in fact, though not in terms, suppose a changing force. And, on the other hand, whenever we suppose the action of a changing force, we suppose the change of motion; for the action of this force, and the change of motion, is one and the same thing. We cannot think of the action without thinking of the indication of that action; that is, the change of motion. In the same manner, when we do not think of a changing force, or suppose that there is no action of a changing force, we in fact, though not in terms, suppose that there is no indication of this changing force; that is, that there is no change.

Whenever, therefore, we suppose that no mechanical force is acting on a body, we in fact suppose that the body continues in its former condition with respect to motion. If we suppose that nothing accelerates, or retards, or deflects the motion, we suppose that it is not accelerated, nor retarded, nor deflected. Hence follows the proposition in express terms—*We suppose that the body continues in its former state of rest or motion, unless we suppose that it is changed by some mechanical force.*

Thus it appears that this proposition is not a matter of experience or contingency, depending on the properties which it has pleased the Author of nature to bestow on body; it is to us a necessary truth. The proposition does not so much express any thing with regard to body, as it does the operations of our mind when contemplating body. It may perhaps be essential to body to move in some particular direction. It may be essential to body to stop as soon as the moving cause has ceased to act; or it may be essential to body to diminish its motion gradually, and finally come to rest. But this will not invalidate the truth of this proposition. These circumstances in the nature of body, which render those modifications of motion essentially necessary, are the causes of those modifications; and in our study of nature they will be considered by us as changing forces, and will be known and called by that name. And if we should ever see a particle of matter in such a situation that it is affected by those essential properties alone, we shall, from observation of its motion, discover what those essential properties are.

This law turns out at last to be little more than a tautological proposition; but mechanical philosophy, as we have defined it, requires no other sense of it; for even if we should suppose that body, of its own nature, is capable of changing its state, this change must be performed according to some law which characterizes the nature of body; and the knowledge of the law can be had in no other way than by observing the deviations from uniform rectilineal motion. It is therefore indifferent whether those changes are derived from the nature of the thing or from external causes; for, in order to consider the various motions of bodies, we must first consider this nature of matter as a mechanical affection of matter, operating in every instance; and thus we are brought back to the law enounced in this proposition. This becomes more certain when we reflect that the external causes (such as gravity or magnetism), which are acknowledged to operate changes of motion, are equally unknown to us with this essential original property of matter, and are, like it, nothing but inferences from the phenomena.

The above very diffuse discussions may appear superfluous to many readers, and even cumbersome; but we trust that the philosophical reader will excuse our anxiety on this head, when he reflects on the complicated, indistinct, and inaccurate notions commonly had of the subject. We may include Sir Isaac Newton in the number of those who have at least introduced modes of expression which mislead the minds of incautious persons, and suggest inadequate notions, incompatible with the pure doctrine of the proposition. Although in words they disclaim the doctrine that rest is the natural state of body, and that force is necessary for the continuation of its motion,

First Law of Motion.

yet in words they (and most of them in thought) likewise abet that doctrine: for they say that there resides in a moving body a *power* or *force*, by which it perseveres in its motion. They call it the *vis insita*, the *inherent force, of a moving body.* This is surely giving up the question: for if the motion is supposed to be continued in consequence of a force, that force is *supposed* to be exerted; and it is supposed that if it were not exerted, the motion would cease; and therefore the proposition must be false. Indeed it is sometimes expressed so as seemingly to ward off this objection. It is said that the body continues in uniform rectilineal motion, unless affected by some *external cause.* But this way of speaking obliges us, at first setting out in natural philosophy, to assert that gravity, magnetism, electricity, and a thousand other mechanical powers, are external to the matter which they put in motion. This is quite improper. It is the business of philosophy to discover whether they be external or not; and if we assert that they are, we have no principles of argumentation with those who deny it. It is this one thing that has filled the study of nature with all the jargon of ethers, and other invisible, intangible fluids, which has disgraced philosophy, and greatly retarded its progress.

Vis insita, inherent force, are improper terms in the usual acceptation.

32. We must observe, that the terms *vis insita*, inherent force, are very improper. There is no dispute among philosophers in calling every thing a force that produces a change of motion, and in inferring the action of such a force whenever we observe a change of motion. It is surely incongruous to give the same name to what has not this quality of producing a change, or to infer (or rather to suppose) the energy of a force when no change of motion is observed. This is one among many instances of the danger of mistake when we indulge in analogical discussions. All our language, at least, on this subject is analogous. I feel that in order to oppose animal force I must exert force. But I must exert force in order to oppose a body in motion; therefore I imagine that the moving body possesses force. A bent spring will drive a body forward by unbending; therefore I say that the spring exerts force. A moving body impels the body which it hits; therefore I say that the impelling body possesses and exerts force. I imagine farther, that it possesses force only by being in motion, or because it is in motion; because I do not find that a quiescent body will put another into motion by touching it. But we shall soon find this to be false in many, if not in all cases, and that the communication of motion depends on the mere vicinity, and not on the motion of the impelling body; yet we ascribe the exertion of the *vis insita* to the circumstance of the continued motion. We therefore conceive the force as arising from or as consisting in the impelling body's being in motion; and, with a very obscure and indistinct conception of the whole matter, we call it *the force by which the body preserves itself in motion.* Thus, taking it for granted that a force resides in the body, and being obliged to give it some office, this is the only one that we can think of.

33. But philosophers imagine that they perceive the necessity of the exertion of a force in order to the continuation of a motion. Motion (say they) is a continued action; the body is every instant in a new situation; there is the continual production of an effect, therefore the continual action of a cause.

Motion is not the continual production of effect.

This, however, is a very inaccurate way of thinking. We have a distinct conception of motion; and we conceive that there is such a thing as a moving cause, which we distinguish from all other causes by the name *force.* It produces motion. If it does this, it produces the character of motion, which is a continual change of place. Motion is not action, but the effect of an action; and this action is as complete in the instant immediately succeeding the beginning of the motion as it is a minute after. The subsequent change of place is the continuation of an effect already produced. The *immediate* effect of the moving force is a *determination*, by which, if not hindered, the body would go on for ever from place to place. It is in this determination only that the state or condition of the body can differ from a state of rest; for in any instant the body does not describe any space, but has a determination by which it will describe a certain space uniformly in a certain time. Motion is a condition, a state, or mode of existence, and no more requires the continued agency of the moving cause than yellowness or roundness does. It requires some chemical agency to change the yellowness to greenness; and it requires a mechanical cause or a force to change this motion into rest. When we see a moving body stop short in an instant, or be gradually but quickly brought to rest, we never fail to speculate about a cause of this cessation or retardation. The case is no way different in itself although the retardation should be extremely slow. We should always attribute it to a cause. It requires a cause to put a body out of motion, as much as to put it into motion. This cause, if not external, must be found in the body itself; and it must have a self-determining power, and may as well be able to put itself into motion as out of it.

If this reasoning be not admitted, we do not see how any effect can be produced by any cause. Every effect supposes something *done;* and any thing done implies that the thing done may remain till it be *undone* by some other cause. Without this it would have no existence. If a moving cause did not produce continued motion by its instantaneous action, it could not produce it by any continuance of that action; because in no instant of that action does it produce continued motion.

We must therefore give up the opinion, that there resides in a moving body a force *by which it is kept in motion;* and we must find some other way of explaining that remarkable difference between a moving body and a body at rest, by which the first causes other bodies to move by hitting them, while the other does not do this by merely touching them. We shall see, with the clearest evidence, that motion is necessary in the impelling body, in order that it may permit the forces inherent in one or both bodies to continue this pressure long enough for producing a sensible or considerable motion. But these moving forces are inherent in bodies, whether they are in motion or at rest.

Communication of motion is an improper phrase;

34. The foregoing observations show us the impropriety of the phrase *communication of motion.* By thus reflecting on the notions that are involved in the general conception of one body being made to move by the impulse of another, we perceive that there is nothing individual transferred from the one body to the other. The determination to motion, indeed, existed only in the impelling body before collision; whereas, afterwards, both bodies are so conditioned or determined. But we can form no notion of the thing transferred. With the same metaphysical impropriety we speak of the communication of joy, of fever.

so is *vis inertiæ.*

35. Kepler introduced a term *inertia, vis inertiæ,* into mechanical philosophy; and it is now in constant use. But writers are very careless and vague in the notions which they affix to these terms. Kepler and Newton seem generally to employ it for expressing the fact, the perseverance of the body in its present state of motion or rest: but they also frequently express by it something like an indifference to motion or rest, *manifested by its requiring the same quantity of force to make an augmentation of its motion as to make an equal diminution of it.* The popular notion is

First Law of Motion.

like that which we have of actual resistance; and it always implies the notion of force *exerted* by the resisting body. We suppose this to be the exertion of the *vis insita*, or the *inherent force* of a body in motion. But we have the same notion of resistance from a body at rest which we set in motion. Now surely it is in direct contradiction to the common use of the word *force*, when we suppose resistance from a body at rest; yet *vis inertiæ* is a very common expression. Nor is it more absurd (and it is very absurd) to say, that a body maintains its state of rest by the exertion of a *vis inertiæ*, than to say that it maintains its state of motion by the exertion of an *inherent force*. We should avoid all such metaphorical expressions as *resistance*, *indifference*, *sluggishness*, or *proneness to rest* (which some express by *inertia*) because they seldom fail to make us indulge in metaphorical notions, and thus lead us to misconceive the *modus operandi*, or procedure of nature.

There is *no resistance whatever observed* in these phenomena, for the force employed always produces its *complete* effect. When I throw down a man, and find that I have employed no more force than was sufficient to throw down a similar and equal mass of dead matter, I know by this that he *has not* resisted; but I conclude that he *has* resisted if I have been obliged to employ much more force. There is therefore no resistance, properly so called, when the exerted force is observed to produce its full effect. To say that there *is* resistance, is therefore a real misconception of the way in which mechanical forces have operated in the collision of bodies. There is no more resistance in these cases than in any other natural changes of condition. We are guilty, however, of the same impropriety of language in other cases, where the cause of it is more evident. We say that colours in grain *resist* the action of soap and of the sun, but that Prussian blue does not. We all perceive that in this expression the word resistance is entirely figurative; and we should say that Prussian blue *resists* soap, if we are right in saying that a body resists any force employed to change its state of motion; for soap must be employed to discharge or change the colour, *and it does change it.* Force must be employed to change a motion, *and it does change it.* The impropriety, both of thought and language, is *plain* in the one case, and it is no less *real* in the other. Both of the terms *inherent force* and *inertia* may be used with safety for abbreviating language, if we be careful to employ them only for expressing *either the simple fact of persevering in the former state*, or *the necessity of employing a certain determinate force in order to change that state, and if we avoid all thought of resistance.*

Deviations from uniform rectilineal motion are the only indications of force.

36. From the whole of this discussion we learn that the deviations from uniform motions are the indications of the existence and agency of mechanical forces, and that they are the only indications. The indication is very simple—mere change of place; it can therefore indicate nothing but what is very simple, the something competent to the production of the very motion that we observe; and when two changes of motion are precisely similar, they indicate the same thing. Suppose a mariner's compass on the table, and that by a small tap with my finger I cause the needle to turn off from its quiescent position ten degrees. I can do the same thing by bringing a magnet near it, or by bringing an electrified body near it, or by the unbending of a fine spring pressing it aside, or by a puff of wind, or by several other methods. In all these cases the indication is the same; therefore the thing indicated is the same, namely, a certain intensity and direction of a moving power. How it operates, or in what manner it exists and exerts itself in these instances, outwardly so different, is not under consideration at present. Impulsiveness, intensity, and direction, are all the circumstances of resemblance by which the affections of matter are to be characterized; and it is to the discovery and determination of these alone that our attention is now to be directed. We are directed in this research by the

SECOND LAW OF MOTION.

Every change of motion is proportional to the force impressed, and is made in the direction of that force.

37. This law also may almost be considered as an identical proposition; for it is equivalent to saying that the changing force is to be measured by the change which it produces, and that the direction of this force is the direction of the change. Of this there can be no doubt, when we consider the force in no other sense than that of the cause of motion, paying no attention to the form or manner of its exertion. Thus, when a pellet of tow is shot from a pop-gun by the expansion of the air compressed by the rammer, or where it is shot from a toy pistol by the unbending of the coiled wire, or when it is nicked away by the thumb like a marble—if, in all these cases, it moves off in the same direction, and with the same velocity, we cannot consider or think of the force, or at least of its exertion, as any how different. Nay, when it is driven forward by the instantaneous percussion of a smart stroke, although the manner of producing this effect (if possible) is essentially different from what is conceived in the other cases, we must still think that the propelling force, considered as a propelling force, is one and the same. In short, this law of motion, as thus expressed by Sir Isaac Newton, is equivalent to saying, "that we take the changes of motion as the measures of the changing forces, and the direction of the change for the indication of the direction of the forces:" for no reflecting person can pretend to say that it is a deduction from the acknowledged principle, that effects are proportional to their causes. We do not affirm this law from having observed the proportion of the forces and the proportion of the changes, and that these proportions are the same; and from having observed that this has obtained through the whole extent of our study of nature. This would indeed establish it as a physical law, an universal fact; and it is, in fact, so established. But this does not establish it as a law of motion, according to our definition of that term; as a law of human thought, the result of the relations of our ideas, as an intuitive truth. The injudicious attempts of philosophers to prove it as a matter of observation, have occasioned the only dispute that has arisen in mechanical philosophy. It is well known that a bullet moving with double velocity penetrates four times as far. Many other similar facts corroborate this: and the philosophers observe, that four times the force has been expended to generate this double velocity in the bullet; it requires four times as much powder. In all the examples of this kind it would seem that the ratio of the forces employed has been very accurately ascertained; yet this is the invariable result. Philosophers, therefore, have concluded that moving forces are not proportional to the velocities which they produce, but to the squares of those velocities. It is a strong confirmation to see that the bodies in motion seem to possess forces in this very proportion, and produce effects in this proportion; penetrating four times as deep when the velocity is only twice as great, &c.

But if this be a just estimation, we cannot reconcile it to the concession of the same philosophers, who grant that the velocity is proportional to the force impressed, in the cases where we have no previous observation of the ratio of the forces, and of its equality to the ratio of the velocities. This is the case with gravity, which these

ond
y of
tion.

philosophers always measure by its accelerating power, or the velocity which it generates in a given time. And this cannot be refused by them; for cases occur where the force can be measured in the most natural manner by the actual pressure which it exerts. Gravity is thus measured by the pressure which a stone exerts on its supports. A weight which at Quito will pull out the rod of a spring steelyard to the mark 312, will pull it to 313 at Spitzbergen; and it is a fact, that a body will fall 313 inches at Spitzbergen in the same time that it falls 312 at Quito. Gravitation is the cause both of the pressure and the fall, and it is a matter of unexcepted observation that they have always the same ratio. The philosophers who have so strenuously maintained the other measure of forces are among the most eminent of those who have examined the motions produced by gravity, magnetism, electricity, &c.; and they never think of measuring those forces any other way than by the velocity. It is in this way that the whole of the celestial phenomena are explained in perfect uniformity with observation, and that the Newtonian philosophy is considered as a demonstrative science.

There must, therefore, be some defect in the principle on which the other measurement of forces is built, or in the method of applying it. Pressure is undoubtedly the immediate and natural measure of force; yet we know that four springs, or a bow four times as strong, give only a double velocity to an arrow.

The truth of our law rests on this only, that we assume the changes of motion as the measure of the changing forces, or at least as the measures of their exertions in producing motion. In fact, they are the measures only of a certain circumstance, in which the actions of very different natural powers may resemble each other, namely, the competency to produce motion. They do not, perhaps, measure their competency to produce heat, or even to bend springs. We can surely consider this apart from all other circumstances, and it is worthy of separate consideration. Let us see what can be, and what ought to be, deduced from this way of treating the subject.

Cnge of
mon is
itf a
mon.

38. The motion of a body may certainly remain unchanged. If the direction and velocity remain the same, we perceive no circumstance in which its condition with respect to motion differs. Its change of place or situation can make no difference; for this is implied in the very circumstance of the bodies being in motion.

But if either the velocity or direction change, then surely is its mechanical condition no longer the same; a force has acted on it, either intrinsic or from without, either accelerating, or retarding, or deflecting it. Supposing the direction to remain the same, its difference of condition can consist in nothing but its difference of velocity. This is the only circumstance in which its condition can differ, as it passes through two different points of its rectilineal path. It is this determination by which the body will describe a certain determinate space uniformly in a given time, which defines its condition as a moving body; the changes of this determination are the measures of their own causes, and to those causes we have given the name *force.* Those causes may reside in other bodies, which may have other properties, characterized and measured by other effects. Pressure may be one of those properties, and may have its own measures; these may or may not have the same proportion with that property which is the cause of a change of velocity; and therefore changes of velocity may not be a measure of pressure. This is a question of fact, and requires observation and experience; but, in the mean time, velocity, and the change of velocity, is the measure of moving force and of changing force. When, therefore, the change of velocity is the same whatever the previous velocity may be, the changing force must be considered as the same. Therefore, finally, if the previous velocity is nothing, and consequently the change on that body is the very velocity or motion that it acquires, we must say, that the force which produces a certain change in the velocity of a moving body is the same with the force which would impart to a body at rest a velocity equal to this change or difference of velocity produced on the body already in motion.

Second
Law of
Motion.

39. This manner of estimating force is in perfect conformity to our most familiar notions on these subjects. We conceive the weight or downward pressure of a body as the cause of its motion downwards; and we conceive it as belonging to the body at all times, and in all places, whether falling, or rising upwards, or describing a parabola, or lying on a table; and, accordingly, we observe, that in every state of motion it receives equal changes of velocity in the same or an equal time, and all in the direction of its pressure.

40. All that we have now said of a change of velocity might be repeated of a change of direction. It is surely possible that the same change of direction may be made on any two motions. Let one of the motions be considered as growing continually slower, and terminating in rest. In every instant of this motion it is possible to make one and the same change on it. The same change may therefore be made at the very instant that the motion is at an end. In this case the change is the very motion which the body acquires from the changing force. Therefore, in this case also, we must say that a change of motion is itself a motion, and that it is the motion which the force would produce in a body that was previously at rest.

How ascertained and measured.

41. The result of these observations is evidently this, that we must ascertain, in every instance, what is the change of motion, and mark it by characters that are conspicuous and distinguishing; and this mark and measure of change must be a motion. Then we must say, that the changing force is that which would produce this motion in a body previously at rest. We must see how this is manifest as a motion in the difference between the former motion and the new motion; and, on the other hand, we must see how the motion produceable in a quiescent body may be so combined with a motion already existing as to exhibit a new motion, in which the agency of the changing force may appear.

Suppose a ship at anchor in a stream, while one man walks forward on the quarter deck at the rate of two miles per hour, another walks from stem to stern at the same rate, a third walks athwart ship, and a fourth stands still. Let the ship be supposed to cut or part her cable, and float down the stream at the rate of three miles per hour. We cannot conceive any difference in the change made on each man's motion in absolute space; but their motions are now exceedingly different from what they were: the first man, whom we may suppose to have been walking westward, is now moving eastward one mile per hour; the second is moving eastward four miles per hour, and the third is moving in an oblique direction, about three points north or south of due east. All have suffered the same change of condition with the man who had been standing still. He has now got a motion eastward three miles per hour. In this instance, we see very well the circumstance of sameness that obtains in the change of these four conditions. It is the motion of the ship which is blended with the other motions. But this circumstance is equally present whenever the same previous motions are changed into the same new motions. We must learn to expiscate this; which we shall do by considering the manner in which the motion of the ship is blended with each of the men's motions.

Second Law of Motion.

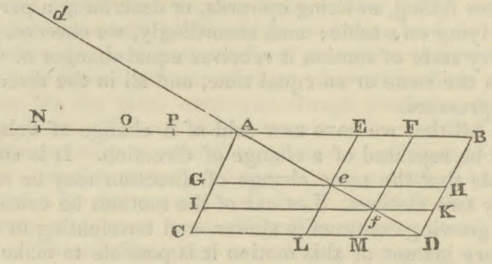
Composition of motion.

42. This kind of combination has been called the *composition of motion;* because, in every point of the motion really pursued, the two motions are to be found.

The fundamental theorem on this subject is this: Two uniform motions in the sides of a parallelogram compose an uniform motion in the diagonal.

Suppose that a point A (fig. 1) describes AB uniformly in some given time, while the line AB is carried uniformly along AC in the same time, keeping always parallel to its first position AB. The point A, by the combination of these motions, will describe AD, the diagonal of the parallelogram ABDC, uniformly in the same time.

Fig. 1.



For it is plain that the velocities in AB and AC are proportional to AB and AC, because they are uniformly described in the same time. When the point has got to E, the middle of AB, the line AB has got into the situation GH, half way between AB and CD, and the point E is in the place *e*, the middle of GH. Draw E*e*L parallel to AC. It is plain that the parallelograms ABDC and AE*e*G are similar; because AE and AG are the halves of AB and AC, and the angle at A is common to both. Therefore, by a proposition in the elements, they are about the same diagonal, and the point *e* is in the diagonal of AD. In like manner, it may be shown, that when A has described AF, three fourths of AB, the line AB will be in the situation IK; so that AI is three fourths of AC, and the point *f*, in which A is now found, is in the diagonal AD. It will be the same in whatever point of AB the describing point A be supposed to be found. The line AB will be on a similar point of AC, and the describing point will be in the diagonal AD.

Moreover, the motion in AD is uniform; for A*e* is described in the time of describing AE; that is, in half the time of describing AB, or in half the time of describing AD. In like manner, A*f* is described in three fourths of the time of describing AD, &c. &c.

Lastly, the velocity in the diagonal AD is to the velocity in either of the sides as AD is to that side. This is evident, because they are uniformly described in the same time.

This is justly called *a composition of the motions* AB *and* AC, as will appear by considering it in the following manner: Let the lines AB, AC be conceived as two material lines like wires. Let AB move uniformly from the situation AB into the situation CD, while AC moves uniformly into the situation BD. It is plain that their intersection will always be found on AD. The point *e*, for example, is a point common to both lines. Considered as a point of EL, it is then moving in the direction *e*H or AB; and considered as a point of GH, it is moving in the direction *e*L. Both of these motions are therefore blended in the motion of the intersection along AD. We can conceive a small ring at *e* embracing loosely both of the wires. This material ring will move in the diagonal, and *will really partake* of both motions.

Thus we see how the motion of the ship is actually blended with the motions of the three men; and the circumstance of sameness which is to be found in the four changes of motion is this motion of the ship, or of the man who was standing still. By composition with each of the three former motions, it produces each of the three new motions. Now, when each of two primitive motions is the same, and each of the new motions is the same, the change is surely the same. If one of the changes has been brought about by the actual composition of motions, we know precisely what that change is; and this informs us what the other is, in whatever way it was produced.

Seco Law Mot

Hence we infer that,

Its ma and m sure.

43. *When a motion is any how changed, the change is that motion which, when compounded with the former motion, will produce the new motion.* Now, because we assume the change as the measure and characteristic of the changing force, we must do so in the present instance; and we must say,

Chang force.

44. *That the changing force is that which will produce in a quiescent body the motion which, by composition with the former motion of a body, will produce the new motion.*

And, on the other hand,

Its eff

When the motion of a body is changed by the action of any force, the new motion is that which is compounded of the former motion, and of the motion which the force would produce in a quiescent body.

Deflec force.

When a force changes the direction of a motion, we see that its direction is transverse in some angle BAC; because a diagonal AD always supposes two sides. As we have distinguished any change of direction by the term *deflection,* we may call the transverse force a *deflecting force.*

In this way of estimating a change of motion, all the characters of both motions are preserved, and it expresses every circumstance of the change; the mere change of direction, or the angle BAD, is not enough, because the same force will make different angles of deflection, according to the velocity of the former motion, or according to its direction. But in this estimation the full effect of the deflecting force is seen; it is seen *as a motion;* for when half of the time is elapsed, the body is at *e* instead of E; when three fourths are elapsed it is at *f* instead of F; and at the end of the time it is at D instead of B. In short, the body has moved uniformly away from the points at which it would have arrived independent of the change; and this motion has been in the same direction, and at the same rate, as if it had moved from A to C by the changing force alone. Each force has produced its full effect; for when the body is at D, it is as far from AC as if the force AC had not acted on it; and it is as far from AB as it would have been by the action of AC alone.

For all these reasons, therefore, it is evident, that if we are to abide by our measure and character of force as a mere producer of motion, we have selected the proper characteristic and measure of a changing force; and our descriptions, in conformity to this selection, must be agreeable to the phenomena of nature, and retain the accuracy of geometrical procedure; because, on the other hand, the results which we deduce from the supposed influence of those forces are formed in the same mould. It is not even requisite that the real exertions of the natural forces, such as pressure of various kinds, &c. shall follow these rules; for their deviations will be considered as new forces, although they are only indications of the differences of the real forces from our hypothesis. We have obtained the precious advantage of mathematical investigation, by which we can examine the law of exertion which characterizes every force in nature.

45. On these principles we establish the following fundamental elementary proposition, of continual and indispensable use in all mechanical inquiries.

S ond L v of M ion.

If a body or material particle be subjected at the same time to the action of two moving forces, each of which would separately cause it to describe the side of a parallelogram uniformly in a given time, the body will describe the diagonal uniformly in the same time.

Fu a- me al the em.

For the body, whose motion AB was changed into AD, had gotten its motion by the action of some force. It was moving along NAB, and when it reached the point A, the force AC acted on it. The primitive motion is the same, or the body is in the same condition in every instant of the primitive motion. It may have acquired this motion when it was in N, or when at O, or any other point of NA. In all these cases, if AC act on it when it is in A, it will always describe AD; therefore it will describe AD when it acquires the primitive motion also in A; that is, if the two forces act on it at one and the same instant. The demonstration may be neatly expressed thus: The change induced by each force on the motion produced by the other is the motion which it would produce in the body if previously at rest. Therefore the motion resulting from joint action is the motion which is compounded of these two motions, or it is a motion in the diagonal of the parallelogram, of which these motions are the sides.

Co posi- tio f for .

This is called the *composition of forces.* The forces which produce the motions along the sides of the parallelogram are called the *simple forces,* or the *constituent forces;* and the force which would alone produce the motion along the diagonal is called the *compound force,* the *resulting force,* the *equivalent force.*

46. On the other hand, the force which produces a motion along any line whatever may be conceived as resulting from the combined action of two or more forces. We may *know* or *observe* it to be so; as when we see a lighter dragged along a canal by two horses, one on each side. Each pulls the boat directly toward himself in the direction of the track-rope; the boat cannot go both ways, and its real motion, whatever it is, results from this combined action. This might be produced by a single force; for example, if the lighter be dragged along the canal by a rope from another lighter which precedes it, being dragged by one horse, aided by the helm of the foremost lighter. Here the real force is not the resulting, or the compound, but the equivalent force.

R lution of ces.

This view of a motion mechanically produced is called the *resolution of forces.* The force in the diagonal is said to be *resolved* into the two forces, having the directions and velocities represented by the sides. This practice is of the most extensive and multifarious use in all mechanical disquisitions. It may frequently be exceedingly difficult to manage the complication of the many real forces which concur in producing a phenomenon; and by substituting others, whose combined effects are equivalent, our investigation may be much expedited. But more of this afterwards.

We must carefully remember, that when the motion AD is once begun, all composition is at an end, and the motion is a simple motion. The two determinations, by one of which the body would describe AB, and by the other of which it would describe AC, no longer *co-exist* in the body. This was the case only *in the instant,* in the very act of changing the motion AB into the motion BD; yet is the motion AD equivalent to a motion which is produced by the *actual composition* of two motions AB and AC; in which case the two motions co-exist in every point of AD.

U l de- m tra- tio ncon- clu e.

47. Accordingly this is the way in which the composition of forces is usually illustrated, and thought to be demonstrated. A man is supposed (for instance) to walk uniformly from A to C on a sheet of ice, while the ice is carried uniformly along AB by the stream. The man's real motion is undoubtedly along AD; but this is by no means a demonstration that the instantaneous or short-lived action of two forces would produce that motion; the man must continue to exert force in order to walk; and the ice is dragged along by the stream. Some indeed express this proof in another way, saying, let a body describe AB, while the space in which this motion is performed is carried along AC. The ice may be carried along, and may, by friction or otherwise, drag the man along with it; but a space cannot be removed from one place to another, nor, if it could, would it take the man with it. Should a ship start suddenly forward while a man is walking across the deck, he would be left behind, and fall toward the stern. We must *suppose* a transverse force, and we must *suppose* the composition of this force without proof. This is no demonstration.

Second Law of Motion.

We apprehend, that the demonstration given above of this fundamental proposition is unexceptionable, when the terms force and deflection are used in the abstract sense which we have affixed to them. The only circumstance in it which can be the subject of discussion is, whether we have selected the proper measure and characteristic of a change of motion. We never met with any objection to it.

Objections to the demonstration of No. 45. It will not apply to pressures.

48. But some have still maintained that it does not evidently appear from these principles, that the motion which results from the joint action of two natural powers, whose known and measurable intensities have the same proportions with AB and BC, and which also exert themselves in those directions, will produce a motion having the direction and proportion of AD. They will not, if the velocities produced by these forces are not in the proportion of those intensities, but in the subduplicate ratio of them. Nay, they say that it is not so. If a body be impelled along AC by one spring, and along AB by two springs equally strong, it will not describe the diagonal of a parallelogram, of which the side AB is double the side AC. They add, that an indefinite number of examples can be given where a body *does not* describe the diagonal of the parallelogram by the joint action of two forces, which separately would cause it to describe the sides. And lastly, they say that at any rate it does not appear evident to the mind, that two *incitements* to motion, having the directions and the same proportion of intensity with that of the sides of a parallelogram, actually generate a third, which is the immediate cause of the motion in the diagonal. An equivalent force is not the same with a resulting force.

49. Yet we see numberless cases of the composition of incitements to motion, and they seem as determinate and as susceptible of being combined by composition, as the things called moving forces, which are measured by the velocities. We see them actually so combined in a thousand instances, as in the example already given of a lighter dragged by two horses pulling in different directions. Experiment even shows, that this composition follows precisely the same rule as the composition of the forces which are measured by the velocities; for if the point A (fig. 1) be pulled by a thread or pressed by a spring in the direction AB, and by another in the direction AC, and if the pressures are proportional to AB and AC, then it will be withheld from moving, if it be pulled or pressed by a third force, acting in the direction A*d*, opposite to AD, the pressure being also proportional to AD. This force acting in the direction A*d*, would certainly withstand an equal force acting in the direction AD; therefore we must conclude that the two pressures AB and AC really generate a force AD. This uniform agreement shows that the composition is deducible from fixed principles; but it does not appear that it can be held as demonstrated by the arguments employed in the case of motions. A demonstration of the composition of pressures is farther

Second Law of Motion.

wanted, in order to render mechanics a demonstrative science.

This composition is of more difficult investigation.

Accordingly, philosophers of the first eminence have turned their attention to this problem. It is by no means easy; being so nearly allied to first principles, that it must be difficult to find axioms of greater simplicity by which it may be proved.

Mechanicians generally contented themselves with the solution given by Aristotle; but this is merely a composition of motions; indeed he does not give it for any thing else, and calls it *συνθεσις των φυ ᾳν.* The first writer who appears to have considered it as different from the mere composition of motions, was the celebrated Dutch engineer Stevinus, in his work *on Sluices;* but his solution is obscure. It was sufficient, however, to convince Daniel Bernoulli of the necessity and the difficulty of the problem. He has given the first complete demonstration of it in the first volume of the commentaries of the Imperial Academy of Sciences at St Petersburg. It is extremely ingenious; but it is tedious and intricate, requiring a series of fifteen propositions to demonstrate that two pressures, having the directions and magnitudes of the sides of any parallelogram, compose a third, which has the direction and magnitude of its diagonal. His first proposition is, that *two equal pressures, acting at right angles, compose a third, in the direction of the diagonal of a square, and having to either of the other two the proportion of the diagonal of a square to its sides.*

M. d'Alembert has greatly simplified and improved this demonstration, by beginning with a case that is self-evident; namely, *if three equal forces are inclined to each other in equal angles of 120°, any one of them will balance the combined action of the other two.* Surely; for neither of them can prevail. Therefore *two* equal forces, inclined in an angle of 120°, produce a third, which has the direction and proportion of the diagonal of the rhombus; for this is equal and opposite to one of the three above mentioned. He then demonstrates the same thing of two equal forces inclined in *any* angle; and by a series of eight propositions more, demonstrates the general theorem. This dissertation is in the Memoirs of the Academy at Paris for 1769. He improves it still farther in a subsequent memoir.

Mr Riccati and Mr Fonsenex, in the Commentaries of me Academy of Turin, have given analytical demonstrations, which are also very ingenious and concise, but require acquaintance with the higher mathematics. There is another very ingenious demonstration in the *Journal des Sçavans* for June 1764, but too obscure for an elementary proposition. It is somewhat simplified by Belidor in his *Ingenieur François.* Frisius, in his *Cosmographia,* has given one, which is perhaps the best of all those that are easily comprehended without acquaintance with the higher mathematics; but we imagine that, although no one can doubt of the conclusion, it has not that intuitive evidence for every step of the process that seems necessary.

Composition of pressures.

50. We here offer another, composed by blending together the methods of Bernoulli and D'Alembert; and we imagine that no objection can be made to any step of it. We limit it entirely to pressures, and do not at all consider nor employ the motions which they may be supposed to produce.

(A.) If two equal and opposite pressures or incitements to motion act at once on a material particle, it suffers no change of motion; for if it yields in either direction by their joint action, one of the pressures prevails, and they are not equal.

Equal and opposite pressures are said to *balance* each other; and such as balance must be esteemed equal and opposite.

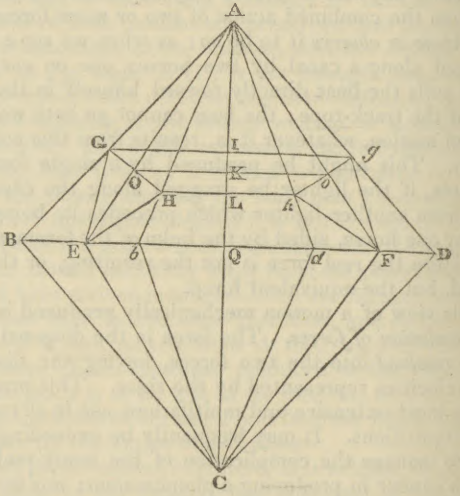
(B.) If a and b are two magnitudes of the same kind, proportional to the intensities of two pressures which act in the same direction, then the magnitude $a+b$ will measure the intensity of the pressure, which is equivalent, and may be called equal to the combined effort of the other two; for when we try to form a notion of pressure as a measurable magnitude, distinct from motion or any other effect of it, we find nothing that we can measure it by but another pressure. Nor have we any notion of a double or triple pressure different from a pressure that is equivalent to the joint effort of two or three equal pressures. A pressure a is accounted triple of a pressure b, if it balances three pressures, each equal to b, acting together. Therefore, in all proportions which can be expressed by numbers, we must acknowledge the legitimacy of this measurement; and it would surely be affectation to omit those which the mathematicians call *incommensurable.*

In like manner, the magnitude $a-b$ must be acknowledged to measure that pressure which arises from the joint action of two pressures a and b acting in opposite directions, of which a is the greatest.

(C.) Let ABCD and AbCd (fig. 2) be two rhombuses, which have the common diagonal AC. Let the angles BAb, DAd, be bisected by the straight lines AE and AF.

If there be drawn from the points E and F the lines EG, EH, Fg, Fh, making equal angles on each side of EA and FA, and if Gg, Hh be drawn, cutting the diagonal AC in I and L: then AI + AL will be greater or less than AQ, the half of AC, according as the angles GEH, gFh, are greater or less than GAH, gAh.

Fig. 2.



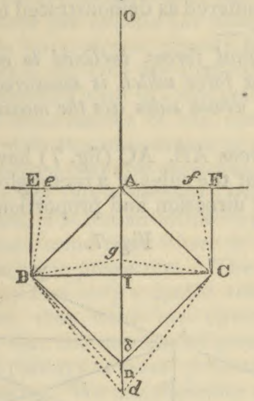
Draw GH, gh, cutting AE, AF, in O and o, and draw Oo, cutting AC in K.

Because the angles AEG and EAG are respectively equal to AEH and EAH, and AE is common to both triangles, the sides AG, GE, are respectively equal to AH, HE, and GH is perpendicular to AE, and is bisected in O; for the same reasons gh is bisected in o. Therefore the lines Gg, Oo, Hh, are parallel, and IL is bisected in K. Therefore AI + AL is equal to twice AK. Moreover, if the angle GEH be greater than GAH, AO is greater than EO, and AK is greater than KQ. Therefore AI + AL is greater than AQ; and if the angle GEH be less than GAH, AI + AL is less than AQ.

(D.) Two equal pressures, acting in the directions AB and AC (fig. 3), at right angles to each other, compose a pressure in the direction AD, which bisects the right angle; and its intensity is to the intensity of each of the constituent pressures as the diagonal of a square to one of the sides.

Second
Law of
Motion.

Fig. 3.



It is evident, that the direction of the pressure, generated by their joint action, will bisect the angle formed by their directions; because no reason can be assigned for the direction inclining more to one side than to the other.

In the next place, since a force in the direction AD does, in fact, arise from the joint action of the equal pressures AB and AC, the pressure AB may be conceived as arising from the joint action of two equal forces similarly inclined and proportioned to it. Draw EAF perpendicular to AD. One of these forces must be directed along AD, and the other along AE. In like manner, the pressure AC may arise from the joint action of a pressure in the direction AD, and an equal pressure in the direction AF. It is also plain that the pressures in the directions AE and AF, and the two pressures in the direction AD, must be all equal. And also, any one of them must have the same proportion to AB or to AC, that AB or AC has to the force in the direction AD, arising from their joint action.

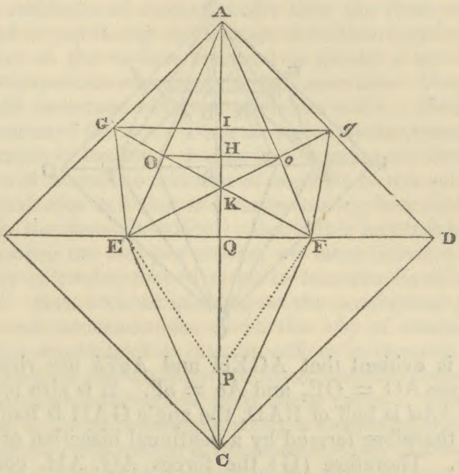
Therefore, if it be said that AD does not measure the pressure arising from the joint action of AB and AC, let A*d*, greater than AD, be its just measure, and make A*d* : AB = AB : A*g* = AB : A*e*. Then A*g* and A*e* have the same inclination and proportion to AB that AB and AC have to A*d*. We determine, in like manner, two forces A*f* and A*g* as constituents of AC.

Now A*d* is equivalent to AB and AC, and AB is equivalent to A*e* and A*g*; and AC is equivalent to A*f* and A*g*. Therefore A*d* is equivalent to A*e*, A*f*, A*g*, and A*g*. But (A) A*e* and A*f* balance each other, or annihilate each other's effect; and there remain only the two forces or pressures A*g*, A*g*. Therefore (B) their measure is a magnitude equal to twice A*g*. But if A*d* be greater than the diagonal AD of the square, whose sides are AB and AC; then A*g* must be less than AI, the side of the square whose diagonal is AB. But twice A*g* is less than AD, and much less than A*d*. Therefore the measure of the equivalent of AB and AC cannot be a line A*d*, greater than AD. In like manner, it cannot be a line Aδ that is less than AD. Therefore it must be equal to AD, and the proposition is demonstrated.

(E.) *Cor.* Two equal forces, AB, AC, acting at right angles, will be balanced by a force AO, equal and opposite to AD, the diagonal of the square whose sides are AB and AC; for AO would balance AD, which is the equivalent of AB and AC.

(F.) Let AECF (fig. 4), be a rhombus, the acute angle of which, EAF, is half of a right angle. Two equal pressures, which have the directions and measures AE, AF, compose a pressure having the direction and measure AC, which is the diagonal of the rhombus.

Fig. 4.



It is evident, in the first place, that the compound force has the direction AC, which bisects the angle EAF. If AC be not its just measure, let it be AP less than AC. Let ABCD be a square described on the same diagonal, and make AP : AQ = AE : AO, = AF : A*o*. Draw KOG, K*og* perpendicular to AE, AF; draw GI*g*, OH*o*, EG, EK, F*g*, FK, PF, and PE.

The angles CAB and FAE are equal, each being half of a right angle. Also the figures AEPF and AGEK are similar; because AP : AQ = AE : AO. Therefore FA : AP = KA : AE, and EA : AP = GA : AE. Therefore, in the same manner that the forces AE, AF are affirmed to compose AP, the forces AG and AK may compose the force AE, and the forces A*g* and AK may compose the force AF. Therefore (B) the force AP is equivalent to the four forces AG, AK, A*g*, AK. But (D) AG and A*g* are the sides of a square, whose diagonal is equal to twice AI; and the two forces AK, AK are equal to, or are measured by, twice AK. Therefore the four forces AG, AK, A*g*, AK, are equivalent to 2 AI + 2 AK = 4 AH.

But because AP was supposed less than AC, the angle FPE is greater than FAE, and GEK is greater than GAK, AO is greater than OE, and AH is greater than HQ, and 2AH is greater than AQ; and therefore 4AH is greater than AC, and much greater than AP. Therefore AP is not the just measure of the force composed of AE and AF.

In like manner it is shown that AE and AF do not compose a force whose measure is greater than AC. It is therefore equal to AC; and the proposition is demonstrated.

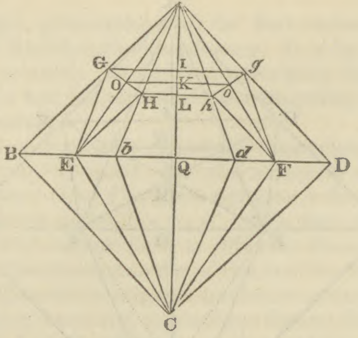
(G.) By the same process it may be demonstrated, that if BAD be half a right angle, and EAF be the fourth of a right angle, two forces AE, AF will compose a force measured by AC. And the process may be repeated for a rhombus, whose acute angle is $\frac{1}{8}$th, $\frac{1}{10}$th, &c. of a right angle; that is, any portion of a right angle that is produced by continual bisection. Two forces, forming the sides of such a rhombus, compose a force measured by the diagonal.

(H.) Let ABCD, A*b* C*d*, (fig. 5), be two rhombuses, formed by two consecutive bisections of a right angle. Let AECF be another rhombus, whose sides AE and AF bisect the angles BA*b* and DA*d*.

The two forces AE, AF, compose a force AC.

Bisect AE and AF in O and *o*. Draw the perpendiculars GOH, *goh*, and the lines GI*g*, OK*o*, HL*h*, and the lines EG, EH, F*g*, F*h*.

Fig. 5.



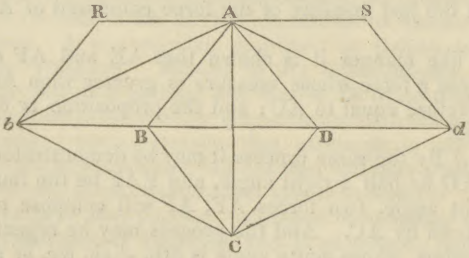
It is evident that $AGEH$ and $AgFh$ are rhombuses; because $AO = OE$, and $Ao = oF$. It is also plain, that since bAd is half of BAD, the angle GAH is half of bAd. It is therefore formed by a continual bisection of a right angle. Therefore (G) the forces AG, AH, compose a force AE; and Ag, Ah, compose the force AF. Therefore the forces AG, AH, Ag, Ah, acting together, are equivalent to the forces AE, AF, acting together. But AG, Ag compose a force $= 2\,AI$; and the forces AH, Ah compose a force $= 2\,AL$. Therefore the four forces acting together are equivalent to $2\,AI + 2\,AL$, or to $4\,AK$. But because AO is $\frac{1}{2}\,AE$, and the lines Gg, Oo, Hh, are evidently parallel, $4\,AK$ is equal to $2\,AQ$, or to AC; and the proposition is demonstrated.

(I.) *Cor.* Let us now suppose that by continual bisection of a right angle we have obtained a very small angle a of a rhombus; and let us name the rhombus by the multiple of a, which forms its acute angle.

The proposition (G) is true of a, $2a$, $4a$, &c. The proposition (H) is true of $3a$. In like manner, because (G) is true of $4a$ and $8a$, proposition (H) is true of $6a$; and because it is true of $4a$, $6a$, and $8a$, it is true of $5a$ and $7a$. And so on continually till we have demonstrated it of every multiple of a that is less than a right angle.

(K.) Let RAS (fig. 6) be perpendicular to AC, and let $ABCD$ be a rhombus, whose acute angle BAD is some multiple of $2a$ that is less than a right angle. Let Ab, Cd be another rhombus, whose sides Ab, Ad bisect the angles RAB, SAD. Then the forces Ab, Ad compose a force AC.

Fig. 6.



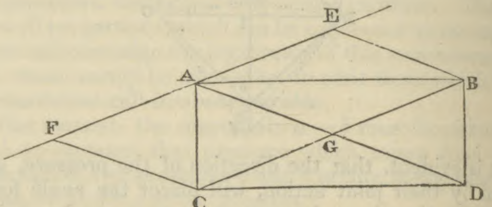
Draw bR, dS parallel to BA, DA. It is evident that $ARbB$ and $ASdD$ are rhombuses, whose acute angles are multiples of a, that are each less than a right angle. Therefore (I) the forces AR and AB compose the force Ab and AS, AD compose Ad; but AR and AS annihilate each other's effect, and there remains only the forces AB, AD. Therefore Ab and Ad are equivalent to AB and AD, which compose the force AC; and the proposition is demonstrated.

(L.) *Cor.* Thus is the corollary of last proposition extended to every rhombus, whose angle at A is some multiple of a less than two right angles. And since a may be taken less than any angle that can be named, the proposition may be considered as demonstrated of every rhombus; and we may say,—

(M.) *Two equal forces, inclined to each other in any angle, compose a force which is measured by the diagonal of the rhombus, whose sides are the measures of the constituent forces.*

(N.) Two forces AB, AC (fig. 7) having the direction and proportion of the sides of a rectangle, compose a force AD, having the direction and proportion of the diagonal.

Fig. 7.

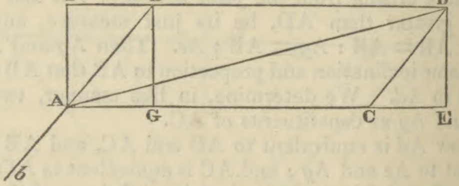


Draw the other diagonal CB, and draw EAF parallel to it: draw BE, CF parallel to DA.

$AEBG$ is a rhombus; and therefore the forces AE and AG compose the force AB. $AFCG$ is also a rhombus, and the force AC is equivalent to AF and AG. Therefore the forces AB and AC, acting together, are equivalent to the forces AE, AF, AG, and AG acting together, or to AE, AF, and AD acting together; but AE and AF annihilate each other's action, being opposite and equal (for each is equal to the half of BC). Therefore AB and AC acting together are equivalent to AD, or compose the force AD.

(O.) Two forces, which have the direction and proportions of AB, AC (fig. 8) the sides of any parallelogram, compose a force having the direction and proportion of the diagonal AD.

Fig. 8.



Draw AF perpendicular to BD, and BG and DE perpendicular to AC.

Then $AFBG$ is a rectangle, as is also $AFDE$; and AG is equal to CE. Therefore (N) AB is equivalent to AF and AG. Therefore AB and AC acting together, are equivalent to AF, AG, and AC acting together; that is, to AF and AE acting together; that is (N) to AD; or the forces AB and AC compose the force AD.

51. Hence arises the most general proposition.

If a material particle be urged at once by two pressures or incitements to motion, whose intensities are proportional to the sides of any parallelogram, and which act in the directions of those sides, it is affected in the same manner as if it were acted on by a single force, whose intensity is measured by the diagonal of the parallelogram, and which acts in its direction: Or, two pressures, having the direction and proportion of the sides of a parallelogram, generate a pressure having the direction and proportion of the diagonal.

52. Thus have we endeavoured to demonstrate from abstract principles the perfect similarity of the composition of pressures, and the composition of forces measured by the motions which they produce. We cannot help being of the opinion that a separate demonstration is indispen-

eeng iffence f th om- ositns f mon nd pres- ure sap- ear hen arely xamed.

sably necessary. What may be fairly deduced from the one case cannot always be applied to the other. No composition of pressures can explain the change produced by a deflecting force on a motion already existing; for the changing pressure is the only one that exists, and there is none to be compounded with it. And, on the other hand, our notions and observations of the composition of motions will not explain the composition of pressures, unless we take it for granted that the pressures are proportional to the velocities; but this is perhaps a gratuitous assumption. At any rate, it is not an intuitive proposition; and we have mentioned some facts where it seems that they do not follow the same proportion. The pressure of four equal springs produces only a double velocity. It would appear, therefore, that there are circumstances which oblige us to say, that the *exertion* of pressure, as a cause of motion, is not (always at least) proportional to the real measurable pressure. We are therefore anxious to discover in what the difference consists; and in the mean time must allow, that the pressure exerted on a body at rest is different from its exertion in producing motion. We cannot indeed state any immediate comparison between pressure and motion, nor have we any clear conception of the connection between them. It is only by our own sensations of touch that we have any notion of pressure, and it is experience that teaches us that it always accompanies every cause of motion. We can, however, observe the proportions of pressures, and compare them with the proportions of motion. We very often observe them different; and therefore it was indispensably necessary to investigate the laws of combined pressure as we did the laws of combined motion in consequence of pressure. Yet we should err if we hastily asserted that pressures are not proportional to the motions which they produce; all that we are entitled to call in doubt is, whether the pressures in their exertion, while they actually produce motion, or changes of motion, continue to be the same as when they do not produce motion, being withstood or balanced by opposite pressures. Considered as causes of motion, we ought to think that they do not vary while they produce motion, and that the actual pressure, while it produces a double motion, is really double, although it may be quadruple when the body exerting it is made to act on a body that it cannot move. We are confirmed in this opinion by observing, that other facts show us, that even while producing motion, the pressure which we call quadruple, because we have measured it by four equal pressures balancing it, is really quadruple, considered as the cause of motion, and produces a quadruple motion. A bow which requires four times the force to draw it to any given extent, will communicate the same velocity to a bundle of four arrows that a bow four times more easily drawn communicates to one arrow, and will therefore produce a quadruple motion. Yet it will only produce a double velocity in the arrow that acquired a simple velocity from a bow having one fourth of the strength.

These discrepancies should excite the endeavours of mechanicians to investigate the laws observed in the action of pressures producing motion. Had this been done with care and with candour, we should not have had the great difference of opinion which still divides philosophers about the measures of moving forces. But a spirit of party, which had arisen from other causes, gave importance to what was at first only a difference of expression, and made the partizans of Mr Leibnitz avail themselves of the figurative language which has done so much harm in all the departments of philosophy. Notwithstanding all our caution, it is hardly possible to avoid metaphorical conceptions when we employ the language of metaphor. The abettors of the Leibnitzian measure of moving forces, or perhaps, to speak more properly, the abettors of the Leibnitzian measure of that force which is supposed to preserve bodies in their condition of motion, insist that the force which is exerted in producing any change of motion is greater in proportion as the motion changed is greater; and they give a very specious argument for their assertion. They appeal to the exertions which we ourselves make. Here we are conscious of the fact. Then they give similar examples of the action of bodies. A clay ball, moving six feet per second, will make the addition of one foot to the velocity of an equal clay ball that is already moving four feet per second in the same direction. But if this last ball be already moving ten feet per second, we must follow it with a velocity of twelve feet in order to increase its velocity one foot. But, without insisting on the numberless paralogisms and inconsistencies which this way of conceiving the matter would lead us into, it suffices to observe, that the phenomena give us abundant assurance that there has been the same exertion in both these cases. This acceleration is always accompanied by a compression of the balls, and the compression is the same in both. This compression is a very good measure of the force employed to produce it; and, in the present case, we need not even trouble ourselves with any rule for its measurement: for surely, when the compression is not different, but the same, the force exerted is the same. This is farther confirmed by observing, that it requires the same force to make the same pit, or to give the same motion, to a piece of clay lying on the table of a ship's cabin, whether the ship be sailing two miles or ten miles per hour.

Thus we see that there are strong reasons for believing, that the exertions of pressure in producing motion, or that the pressures *actually exerted*, are proportional to the changes of motion observed, and that they coincide in this respect with our abstract conceptions of moving forces.

But we have still better arguments. None of the Leibnitzians think of denying the equal exertions of gravity, or of any of those powers which they call *solicitations or accelerating forces*. They all admit that gravity, or any constant accelerating force, produces equal increments of velocity in equal times, and that a double gravity will produce a double increment in an equal time, and an equal increment in half of the time: and that a quadruple gravity will produce a double velocity in half the time. All these things are granted by them, and their writings are full of reasonings from this principle. Now, from the fact, acknowledged by the Leibnitzians, that the quadruple force of a bow gives a double velocity to the arrow, in every instant of its action, it indisputably follows, that it has acted on it only for half the time of the action of the four times weaker bow, which gives the arrow only half the velocity; and thus has the discrepancy between the effects of pressures and of our abstract moving forces entirely disappeared. For this circumstance of the difference in the time of acting will be found, on strict examination, in all the cases of the change of motion by pressures which we measure by their effects on a body at rest. When this and the appreciable changes of actual pressure, during the time of producing the motion, are taken into consideration, all difference vanishes, and the composition of pressures is in perfect harmony with the composition of motions, or of abstract moving forces. Dynamics is thus made a demonstrative science, and affords the opportunity of investigating, by observation and experiment, the nature of those mechanical powers which reside in bodies, and which appear to us under the form of pressure, inducing us to consider pressure as a cause of motion.

In this, however, we are rather inaccurate. Pressure is one of the sensible effects of that property which is also

Second Law of Motion.

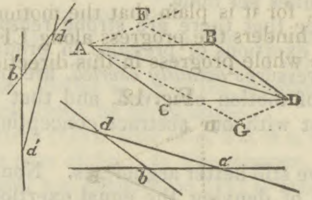
the cause of motion. It is not the pressure of a piece of lead, but its heaviness, that is the reason that it gives motion to a kitchen jack. Pressure is merely a generic name, borrowed from a similar instance, and given to moving forces, which have the same nature, but different names that serve to mark their connection with certain substances, in which they may be supposed to reside. Natural philosophy is almost entirely employed in examining the nature of these various pressures or accelerative forces; and the general doctrines of dynamics, by ascertaining what is common to them all, enable us to mark with precision what is characteristic of each.

General corollaries.

53. We have now advanced very far in this investigation; for we have obtained the criterion by which we learn the direction and the magnitude of every changing force; and, on the other hand, we see how to state what will be the effect of the exertion of any force that is known or suspected to act. All this we learn by the composition of forces; and the greatest part of mechanical disquisition consists in the application of this doctrine. For such reasons it merits minute consideration; and therefore we must point out some general conclusions from the properties of figure, which will greatly facilitate the use of the parallelogram of forces.

54. *First*, The constituent and the resulting forces, or the simple and compound forces, act in the same plane; for the sides and diagonal of a parallelogram are in one plane.

Fig. 9.



55. *Second*, The simple and the compound forces are proportional to the sides of any triangle which are parallel to their directions. For if any three lines, *ab*, *bd*, *ad*, be drawn parallel to AB, AC, and AD (fig. 9), they will form a triangle similar to the triangle ABD. For the same reasons they are proportional to the sides of a triangle *a′b′d*, which are respectively perpendicular to their directions.

56. *Third*, Therefore each is proportional to the sine of the opposite angle of this triangle; for the sides of any triangle are proportional to the sines of the opposite angles.

57. *Fourth*, Each is proportional to the sine of the angle contained by the directions of the other two; for AD is to AB as the sine of the angle ABD to the sine of the angle ADB. Now the sine of ABD is the same with the sine of BAC contained between the directions AB and AC, and the sine of ADB is the same with the sine of CAD; also AB is to AC, or BD, as the sine of ADB (or CAD) to the sine of BAD.

Some special uses of the parallelogram of forces.

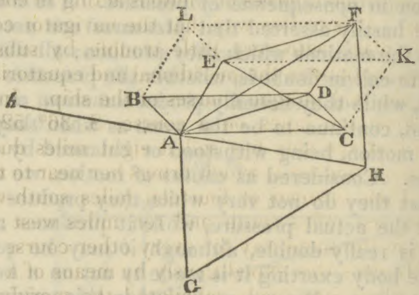
58. We now proceed to the application of this fundamental proposition. And we observe, in the first place, that since AD may be the diagonal of an indefinite number of parallelograms, the motion or the pressure AD may result from the joint action of many pairs of forces. It may be produced by forces which would separately produce the motions AF and AG. This generally gives us the means of discovering the forces which concur in its production. If one of them, AB, is known in direction and intensity, the direction AC, parallel to BD, and the intensity, are discovered. Sometimes we know the directions of both. Then, by drawing the parallelogram or triangle, we learn their proportions. The force which deflects any motion AB into a motion AD, is had by simply drawing a line from the point B (to which the body would have moved from A in the time of really moving from A to D) to the point D. The deflecting force is such as would have caused the body move from B to D in the same time. And, in the same manner, we get the compound motion AD, which arises from any two simple motions AB and AC, by supposing both of the motions to be accomplished in succession. The final place of the body is the same, whether it moves along AD or along AB and BD in succession.

Se L M

59. This theorem is not limited to the composition of two motions or two forces only; for since the combined action of two forces puts the body into the same state as if their equivalent alone had acted on it, we may suppose this to have been the case, and then the action of a third force will produce a change on this equivalent motion. The resulting motion will be the same as if only this third force and the equivalent of the other two had acted on the body. Thus, in fig. 10, the three forces AB, AC, AE, may act at once on a particle of matter. Complete the parallelogram ABDC; the diagonal AD is the force which is generated by AB and AC. Complete the parallelogram AEFD; the diagonal AF is the force resulting from the combined action of the forces AB, AC, and AE. In like manner, completing the parallelogram AGHF, the diagonal AH is the force resulting from the combined action of AB, AC, AE, and AG, and so on of any number of forces.

Equi lent many ces.

Fig. 10.



This resulting force and the resulting motion may be much more expeditiously determined, in any degree of composition, by drawing lines in the proportion and direction of the forces in succession, each from the end of the preceding. Thus, draw AB, BD, DF, FH, and join AH; AH is the resulting force. The demonstration is evident.

60. It is to be noticed here, that in the composition of more than two forces, we are not limited to one plane. The force AD is in the same plane with AB and AC; but AE may be elevated above this plane, and AG may lie below it. AF is in the plane of AD and AE, and AH is in the plane of AF and AG.

Complete the parallelograms ABLE, ACKE, ELFK. It is evident that ABLFKCD is a parallelopiped, and that AF is one of its diagonals. Hence we derive a more general theorem of great use.

Three forces having the proportion and direction of the three sides of a parallelopiped, compose a force having the proportion and direction of the diagonal.

One f may b lance acting gether

61. Any number of forces acting together on one particle of matter are balanced by a force that is equal and opposite to their resulting force; for this force would balance their resulting force which is equivalent to them in action. When this is duly considered, we perceive that each force is then in equilibrio with the equivalent of all

Se nd L of M on.

the others; for a force can balance only what is equal and opposite to it. It appears very readily by the geometrical construction. If, instead of the circuit A, B, D, F, H, we take B, D, F, H, A, we have BA for the equivalent of the forces AC, AE, AG; but AB is equal and opposite to BA. Therefore the force AB is in equilibrio with the equivalent of all the others.

62. When any number of forces act on one particle of matter, and are in equilibrio, if they be considered as acting in parcels, the equivalents of these parcels are in equilibrio; for let the forces AB, AC, AE, AG, A*h*, be in equilibrio, and let them be considered in the two parcels AB, AC, and AE, AG, A*h*, then AD is the equivalent of AB, BD (or AC), and DA is the equivalent of DF, FH, HA (or A*h*): now AD and DA balance each other. This corollary enables us to simplify many intricate complications of force; it also enables us to draw accurate conclusions from very imperfect observations. In most of our practical discussions we know, or at least we attend to, a part only of the forces which are acting on a material particle; and in such cases we reason as if we saw the whole: yet is our mathematical reasoning good with respect to the equivalent of all the parcels which we are contemplating, and the equivalents of the smaller parcels of which it consists; and the neglected force, or parcel of forces, induces no error on our conclusions.

Ex li-tio me-tho for obt ing the sult-ing otion in pli-cat cases.

63. In the spontaneous phenomena of nature, the investigation and discovery of our ultimate object of search is frequently very difficult, on account of the multiplicity of directions and intensities of the operating forces or motions. We may generally facilitate the process, by substituting equivalent forces or motions acting in convenient directions. It is in this way that the navigator computes the ship's place with very little trouble, by substituting equivalent motions in the meridional and equatorial directions for the real oblique courses of the ship. Instead of setting down ten miles on a course, S. 36° 52′ W. he supposes that the ship has sailed eight miles due south, and six miles due west, which brings her near to the same place. Then, instead of fourteen miles south-west, he sets down ten miles south and ten miles west; and he proceeds in the same way for every other course and distance. He does this expeditiously by means of a traverse table, in which are ready calculated the meridional and equatorial sides of right-angled triangles, corresponding to every course and distance. Having done this for the course of a whole day, he adds all the southings into one sum, and all the westings into another; he considers these as forming the sides of a right-angled triangle; he looks for them, paired together, in his traverse table, and then notices what angle and what distance corresponds to this pair. This gives him the position and magnitude of the straight line joining the beginning and end of his day's work.

The miner proceeds in the same way when he takes the plan of subterraneous workings, measuring, as he goes along, and noticing the bearing of each line by the compass, and setting down, from his traverse table, the northing or southing, and the easting or westing, for each oblique line: but there is another circumstance which he must attend to, namely, the slope of the various drifts, galleries, and other workings. This he does by noting the rise or the dip of each sloping line. He adds all these into two sums, and taking the risings from the dips, he obtains the whole dip. Thus he learns how far the workings proceed to the north, how far to the east, and how far to the dip.

The reflecting reader will perceive that the line joining the two extremities of this progression will form the diagonal of a rectangular parallelopiped; one of whose sides lies north and south, the other lies east and west, and the third is right up and down.

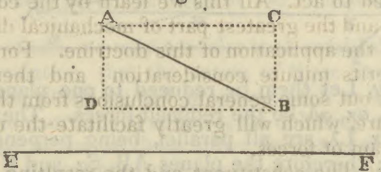
Second Law of Motion.

The mechanician proceeds in the very same way in the investigation of the very complicated phenomena which frequently engage his attention. He considers every motion as compounded of three motions in some convenient directions, at right angles to each other. He also considers every force as resulting from the joint action of three forces, at right angles to each other, and takes the sum or difference of these in the same or opposite directions. From this process he obtains the three sides of a parallelopiped, and from these computes the position and magnitude of the diagonal. This is the motion or force resulting from the composition of all the partial ones.

Forces may be estimated by, or reduced to,

This procedure is called the *estimation* or *reduction* of motions and forces.

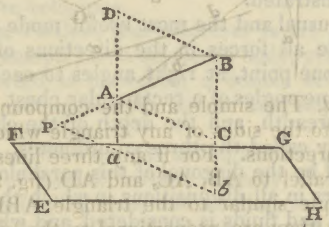
Fig. 11.



a given direction,

64. A motion or force AB (fig. 11) is said to be *estimated* in the direction EF, or to be *reduced* to this direction when it is conceived as compounded of the motions or forces AC, AD, one of which, AC, is parallel to EF, and the other, AD, is perpendicular to it. This expression is abundantly significant; for it is plain that the motion AD neither promotes nor hinders the progress along EF, and that AC expresses the whole progress in this direction.

Fig. 12.



or a given plane.

65. In like manner, a force AB (fig. 12) is said to be *estimated in*, or *reduced to*, a given plane EFG when it is conceived as resulting from the joint action of two forces AC, AD, one of which is parallel to a line *ab* drawn in that plane, and the other AD is perpendicular to it. The position of the line *ab* is determined by letting fall B*b* perpendicular to the plane, and drawing *b*P to the point P, in which BA meets the plane; then A*a* being drawn parallel to B*b*, will cut off *ba*, which is the reduction of the motion AB to the plane. Drawing AC parallel to *ab*, and completing the parallelogram ACBD, it is evident that the motion AB is equivalent to AD and AC, which is parallel to *ab*, and the three forces AB, AC, AD, are, as they should be, in one plane perpendicular to the plane EG.

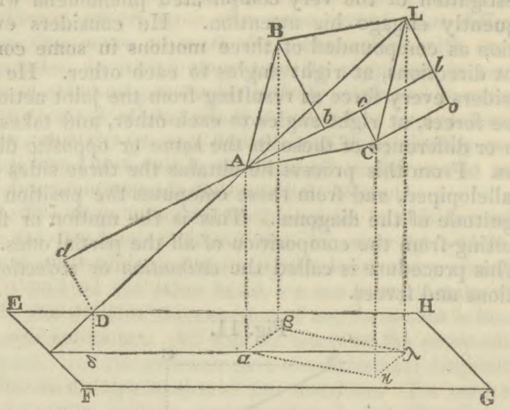
Equilibrium of forces so estimated or reduced.

66. If three forces AB, AC, AD (fig. 13) are in equilibrio, and are reduced to any one direction *d*A*l*, or to one plane EFGH, the reduced forces are also in equilibrio.

First, let them be reduced to one direction *dl* by drawing the perpendiculars B*b*, C*c*, D*d*; make AL equal to AD, and join BL, CL, and draw the perpendiculars L*l*, C*c*; then, because the forces AB, AC, AD, are in equilibrio, ABLC must be a parallelogram, and AL is the force equivalent to AB and AC combined; then, because the lines D*d*, B*b*, C*c*, L*l*, are parallel, *d*A is equal to A*l*, and A*b* to C*o*, or to *cl*; therefore A*l* is equal to the sum of A*b* and A*c*, which are the reductions of AB and AC;

therefore dA is equal to the same sum, and in equilibrio with them.

Fig. 13.



Secondly, Let them be reduced to one plane, EFGH, and let $\alpha\beta$, $\alpha\varkappa$, $\alpha\delta$, be the reduced forces. The lines Dδ, Aα, Bβ, C$\varkappa$, Lλ, are all parallel, being perpendicular to the plane; therefore the planes AB, $\beta\alpha$, and CL, $\lambda\varkappa$, are parallel, and $\alpha\beta$, $\varkappa\lambda$, are parallel. For similar reasons, $\beta\lambda$, $\alpha\varkappa$, are parallel; therefore $\alpha\beta\lambda\varkappa$ is a parallelogram. Also, because the lines Dδ, Aα, Lλ, are parallel, and DA is equal to AL; therefore $\delta\alpha$ is equal to $\alpha\lambda$. But because $\alpha\beta\lambda\varkappa$ is a parallelogram, the forces $\alpha\beta$, $\alpha\varkappa$, are equivalent to $\alpha\lambda$; and $\alpha\delta$ is equal and opposite to $\alpha\lambda$, and will balance it; and therefore will balance $\alpha\beta$ and $\alpha\varkappa$, which are the reductions of AB and AC to the plane EFGH, while $\alpha\delta$ is the reduction of AD; therefore the proposition is demonstrated.

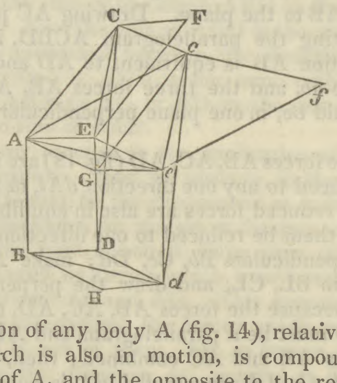
The most useful mode of reduction is to their co-ordinates.

The most usual and the most useful mode of reduction is to estimate all forces in the directions of three lines drawn from one point, at right angles to each other, like the three plane angles of a rectangular chest, forming the length, the breadth, and the depth of the chest. These are commonly called the three co-ordinates. The resulting force will be the diagonal of this parallelopiped. This process occurs in all disquisitions in which the mutual action of solids and fluids is considered, and when the oscillation or rotation of detached free bodies is the subject of discussion.

Relative motions of bodies not affected by any extraneous equal and parallel force.

67. The only other general theorem that remains to be deduced from this law of motion is, that if a number of bodies are moving in any manner whatever, and an equal force act on every particle of matter in the same or parallel directions, their relative motions will suffer no change; for the motion of any body A (fig. 14), relative to another body B, which is also in motion, is compounded of the real motion of A, and the opposite to the real motion of B; for let A move uniformly from A to C, while B describes BD uniformly; draw AB, also draw AE equal and parallel to BD; join EC, DC, ED. The motion of A, relative to B, consists in its change of position and distance. Had A described AE, while B described BD, there would have been no change of relative place or distance; but A is now at C, and DC is its new direction and distance. The relative or apparent motion of A therefore is EC. Complete the parallelogram ACFE; it is plain that the motion EC is compounded of EF, which is equal and parallel to AC, the real motion of A, and of EA, the equal and opposite to BD, the real motion of B.

Fig. 14.



Now let the motions of A and B sustain the same change; let the equal and parallel motions AG, BH, be compounded with the motions AC and BD; or let forces act at once on A and B, in the parallel directions AG, BH, and with equal intensities; in either supposition, the resulting motions will be Ac, Bd, the diagonals of the parallelograms AGcC and BHdD. Construct the figure as before, and we see that the relative motion is now ec, and that it is the same with EC both in respect of magnitude and position.

Here we still see the constant analogy between the composition of motions and the composition of forces. In the first case, the relative motions of things are not changed, whatever common motion be compounded with them all; or, as it is usually but inaccurately expressed, although the space in which they move be carried along with any motion whatever. In the second case, the relative motions and actions are not changed by any external force, however great, when equally exerted on every particle in parallel directions.

Thus it is that the evolutions of a fleet in a uniform current are the same, and produced by the same means, as in still water. Thus it is that we walk about on the surface of this globe in the same manner as if it neither revolved round the sun, nor turned round its axis. Thus it is that the same strength of a bow will communicate a certain velocity to an arrow, whether it is shot east, or west, or north, or south. Thus it is that the mutual actions of sublunary bodies are the same, in whatever directions they are exerted, and notwithstanding the very great changes in their velocities by reason of the earth's rotation and orbital revolution. The real velocity of a body on the earth's equator is about 3000 feet per second greater at midnight than at mid-day. For at midnight the motion of rotation nearly conspires with the orbital motion, and at mid-day it nearly opposes it. The difference between the velocities at the beginning of January and the beginning of July is vastly greater. And at other times of the day, and other seasons of the year, both motions of the earth are transversely compounded with the easterly or westerly motion of an arrow or cannon bullet; yet we can observe no change in the effects of the mutual actions of bodies.

68. This is an important observation, because it proves that forces are to be measured by no other scale than by the motions which they produce. We have had repeated occasions to mention the very different estimation of moving forces by Mr Leibnitz; and have shown how, by a very partial consideration of the action of those natural powers called *pressures*, he has attempted to prove that moving forces are proportional to the squares of the velocities; and we showed briefly in what manner a right consideration of what passes when motion is produced by measurable pressures, proves that the forces really exerted are as the velocities produced. But the most copious proof is had from the present observation, that, in fact, the mutual actions of bodies depend on their relative motions alone.

69. The Leibnitzian measure of moving force is altogether incompatible with the universal fact now mentioned,

tion

viz. that the relative motions of bodies, resulting from their mutual actions, are not affected by any common motion, or the action of any equal and parallel force on both bodies; for this universal fact imports, that when two bodies are moving with equal velocities in the same direction, a force applied to one of them, so as to increase its velocity, gives it the same motion relative to the other, as if both bodies had been at rest. Here it is plain that the space described by the body in consequence of the primitive force, and of the force now added, is the sum of the spaces which each of them would generate in a body at rest. Therefore the forces are proportional to the velocities or changes of motion which they produce, and not to the squares of those velocities. This measure of forces, or the position that a force makes the same change on any velocity whatever, and the independence of the relative motions on any motion that is the same on all the bodies of a system, are counterparts of each other. Since this independence is a matter of observation in all terrestrial bodies, we are entitled to say that the powers which the Author of nature has imparted to natural bodies are no way different from what are competent to matter once called into existence. And it also follows from this, that we must always remain ignorant of the absolute motions of bodies. The fact that it has required the unremitted study of ages to discover even the relative motions of our solar system, is an argument to prove that the influence of this mechanical principle extends far beyond the limits of this sublunary world; nor has any phenomenon yet been exhibited which should lead us to imagine that it is not universal.

So er-
no 's de-
fen of

When we have made use of these arguments with some zealous partizans of Mr Leibnitz's doctrine, they have answered, that if indeed this independence of the relative motions of terrestrial bodies were observed to obtain exactly, it would be a conclusive argument. But the motion with which all is carried along is so great in comparison with the motions which we can produce in our experiments, that the small additions or diminutions that we can make to the velocity of this common motion must observe very nearly the proportions of the additions or diminutions of their squares. The differences of the squares of 2, 3, and 4, are very unequal; but the differences of the squares of 9, 10, 11, are much nearer to the ratio of equality; and the differences of the squares of 1000001, 1000002, 1000003, do not sensibly deviate from this ratio. But it is not fact that we cannot produce motions which have a very sensible proportion to the common motion. The motion of a cannon ball discharged with one third of its weight of powder, is nearly equal to that of the rotation of the earth's equator. When, therefore, we discharge the ball eastward, we double its motion; when to the westward, we destroy it. Therefore, according to Leibnitz, the action in the first case is three times the action in the second. In the first case it changes the square of the velocity (which we may call 1) from 1 to 4; and, in the second, it changes it from 1 to 0. But, say the Leibnitzians, the velocity of rotation is but $\frac{1}{63}$ of the orbital velocity of the earth, and our observations of the velocities of cannon bullets are not sufficiently exact to ensure us against an error of $\frac{1}{31\frac{1}{2}}$. But the latter observations on the peculiar motions of the fixed stars concur in showing, that the sun, with his attending planets, are carried along with a very great motion, which, in all probability, has a sensible ratio to the orbital motion of the earth. This must make a prodigious change on the earth's absolute motion, according as her orbital motion conspires with, opposes, or crosses, this other motion; the earth may even be at absolute rest in some points of its orbit. Thus will the composition with the motions produced in our experiments be so varied that cases *must* occur when the difference of the results of the two measures of force will be very sensible.

Second
Law of
Motion.

But, further, they have not attended to the agreement of our experiments when the discharges of cannon are made in a direction transverse to that of the common motion. Here the immensity of the common motion, and the minuteness of our experimental velocities, can have no effect in diminishing the difference of the results of the two doctrines. This will appear distinctly to every reader who is much conversant in disquisitions of this kind; and it is in these more moderate motions that the complete independence of the relative motions on the common motions most accurately appears. Pendulum clocks and watches have been often executed which do not deviate from perfect equability of motion one part in 86,400. This could not be obtained in all directions of the oscillations, if the forces deviated from the ratio of the velocities one part in 86,400.

Perfect
agreement
of the abstract notion of
force with
all our accurate observations
of the exertions of
natural
powers.

On the whole, we may consider it as established on the surest foundation, that the action of those powers of natural bodies which we call *pressures*, such as the force of springs, the exertions of animals, the cohesion of bodies, as well as the action of those other incitements to motion which we call *attractions* and *repulsions*, such as gravitation, magnetism, and electricity, is proportional to the change of velocity produced by it. And we must observe here, that this is not a mere mode of conception, the result of the laws of human thought, which cannot conceive a natural power as the cause of motion otherwise than by its producing motion, and which cannot conceive any degree of *moving* power different from the degree of the motion. This is the abstract doctrine, and is true whether the pressures are proportional to the velocities or to the squares of the velocities.

But we see further, that whatever is the pressure of a spring (for example) on a quiescent body, yet the pressure actually exerted in producing a double velocity is only double, and not quadruple, as our first imperfect observations make us imagine.

Newton's
third law
of motion
is founded
on experience alone,
and is not
a necessary
truth.

70. Sir Isaac Newton has added another proposition to the number of laws of motion; namely, that *every action is accompanied by an equal and contrary re-action*. But in affirming this to be a law of nature, he only means that it is a universal fact: and he makes this affirmation on the authority of what he conceives to be a law of human thought; namely, that those qualities which we find in all bodies on which we can make experiments and observations, are to be considered as universal qualities of body. But we have limited the term *law of motion* to those consequences that necessarily flow from our notions of motion, of the causes of its production and changes. Now this third Newtonian proposition is not such a result. A magnet is said to act on a piece of iron, when, and only when, the vicinity of the magnet is observed to be accompanied by certain motions of the iron. But it by no means follows from this observation, that the presence of the iron shall be accompanied by any motion, or any change of state whatever of the magnet, or any appearance that can suggest the notion that the iron acts on the magnet. When this was observed, it was accounted a discovery. Newton *discovered* that the sun acts on the planets, and that the earth acts on the moon; and Kepler *discovered* that the moon re-acts on the earth. Newton had observed that the iron re-acts on the magnet; that the actions of electrified bodies were mutual; and that every action of sublunary bodies was, in fact, accompanied by an equal and contrary re-action. On the authority of his rule of philosophizing, he affirmed that the planets re-act on the sun, and that the sun is not at rest, but is continually agi-

tated by a small motion round the general centre of gravitation. He pointed out several consequences of this re-action. Astronomers examined the celestial motions more narrowly, and found that those consequences do really obtain, and disturb all the planetary motions. It is now found that this reciprocity of action obtains throughout the solar system with the utmost precision, and that the third Newtonian proposition is really a law of nature, although it is not a law of human thought. It is a discovery. The contrary involves no absurdity or contradiction. It would indeed be contrary to experience; but things might have been otherwise. It is conceivable and possible that a ball A shall strike another equal ball B, and carry it along with it, without any diminution of its velocity. The fact that the velocity of A is reduced to one half, is the indication of a force residing in B, which force changes the motion of A; and the intensity of this force is learned from the change which it produces. This is found to be equal to the change produced by A on B. And thus the re-action of B is *discovered* to be equal to the action of A.

It is highly probable that this universality and equality of re-action to action is the consequence of some general principle, which we may in time discover; meanwhile we are entitled to suppose it universal, and to reason from this topic in our disquisitions about the actions of bodies on each other.

Maupertuis, Leibnitz, and other philosophers, have entertained very inadequate opinions concerning the foundation of the laws of motion.

Although the celebrated philosophers of Europe have at last agreed in the reception of the two propositions so largely discussed by us as the laws of motion, they have differed exceedingly in their opinion about their origin and validity. Some asserted that they are entirely matters of experience, while others affirmed them to be necessary truths. The Royal Academy of Berlin made this question the subject of their prize dissertation in the year 1744. Mr Maupertuis, president of the academy, published a dissertation, in which he endeavoured to prove that they are necessary truths, only because *they are such as make the quantity of action the least possible*, an economy which is worthy of infinite wisdom, and therefore certainly directs the choice of the Author of nature. On this account alone are they necessary truths.

But this is not the way to consider a question of this kind. We know too little about infinite wisdom to be able to say, with Messrs Leibnitz and Maupertuis, that the Deity should or should not impress on bodies laws different from those which are essential to matter; and we are not to inquire whether God could or could not do this. We know from our own experience, that matter, when subjected to the action of intelligence, may be moved in a way extremely different from what it would follow if left to itself, and that its motions may either be regulated by fixed but contingent law, or may be without any constancy whatever, and vary in every instance. When we suppose the existence of matter and motion, a variety of truths are involved in the supposition, in the same manner as all the theorems in the third book of Euclid's *Elements* are involved in the conception of a circle and a straight line. Our first employment should be to evolve those truths. We can do this in no way but by first noticing the relations of the ideas that we have of the different objects of contemplation, and then following the laws of human thought in our judgments concerning those relations. This process of the mind is expressed in the train of a geometrical demonstration. The different parts or argumentations of this train are not the causes of our conclusions, but the means by which we form our judgment; not the reasons of the truth of our ultimate conclusion, but the steps by which we arrive at the knowledge of it. The young geometer generally thinks otherwise. But that this is the matter of fact, is plain from this, that more than one demonstration, and often very different, can be given of the same theorem. We must proceed in the same manner in the present question; and the first general truths which we find involved in the notions of matter, motion, and force, must be received as *necessary* truths. The steps by which we arrive at the discovery are the laws of human thought; and the expression of the discovery, involving both the truth itself, and the manner of conceiving it, is a necessary law of motion. There may be other facts, perhaps as general as any of those necessary laws, but which do not necessarily result from the relations of our notions of motion and of force. These are discovered by observation only, and they serve to characterize the forces which nature presents to our view. These facts are *contingent* laws of motion.

We apprehend that this method has been followed in treating this article. The first proposition, termed *a law of motion*, is only a more convenient way of expressing our contemplation of a motion in body as an effect of the general cause which we term *force*. The second proposition does nothing but express more distinctly the relation between this cause and its effect; it expresses what we mean by the magnitude and the kind of the cause. The proposition, stating the composition of forces, is but another form of the same law, better suited to the ordinary procedure in geometrical disquisitions.

These propositions might have completed the doctrines of dynamics; but it appears that, in order to the production of a material universe which should accomplish the purposes of the Creator, it was necessary that there be certain characteristic differences between the forces inherent in the various collections of matter which compose this universe. The facts or physical laws (for the above-mentioned laws are metaphysical) of motion may be different from those which would have been observed had matter been left entirely to itself. This difference may have introduced other laws of motion as necessarily resulting from the nature of the forces. We have occasionally mentioned some instances where this appears to obtain, but gave good reasons for affirming that a due examination of all circumstances which may be observed in the production or variation of motion by those forces, has demonstrated, that there are no such deviations from the two laws of motion already determined, but that all the mechanical powers of bodies, when considered merely as causes of motion, act agreeably to the same laws. Careful examination was, however, said to be necessary.

This examination must consist in distinctly noticing the circumstances that occur in the production of motion by any force whatever. It is by no means enough to state simply the intensity of the force and the direction of its exertion. If a force continue to act, it continues to vary the motion already produced. Should the force change its intensity or direction while it is acting, these circumstances must induce still farther changes in the motion; and it is not till all action has ceased that the motion is brought to its ostensible state, in which it is the object of our attention and our future discussions. Instances of the effects of such continued and such varied actions are to be seen in most of the phenomena of nature or art. The communication of motion by impulse is perhaps the only instance (very frequent indeed) that can be produced where this is not necessary; nay, we shall perhaps find reason to conclude that this instance is not an exception, and that even the communication of motion from one billiard ball to another is brought about by an action continued for some time, and greatly varied during that time. Much preparation is therefore necessary before we can apply the general laws of motion to the solution of most of the questions which come before us in the course even of our elementary disquisitions. We must lay down some general propositions which determine the results of the continued, and perhaps varied, actions of moving forces; and we must mark the different effects of the simple continuation of action, and also those of the variations in this continued action, both in respect of intensity and direction. The effect of a mere continuance of action must be an acceleration of the motion, or a retardation of it if the force continue to act in the opposite direction. The effect of the continued action of a transverse force must be a continual deflection, that is, a curvilineal motion. These must therefore now occupy our attention in their order.

OF ACCELERATED AND RETARDED MOTIONS.

Circumstantial exposition of our conception of the condition of a body in respect to motion.

71. All men can perceive that a stone dropped from the hand, or sliding down an uniform slope, has its motion continually accelerated, and that the motion of an arrow rising perpendicularly through the air is continually retarded; and they feel no difficulty in conceiving these changes of motion as the effects of the continual operation of their weight or heaviness. The falling stone is in a different condition in respect of motion in the beginning and end of its fall. In what respect do these states of the body differ? Only in respect to what we call its *velocity*. This is an affection of motion; it is an expression of the relation between the two notions or ideas which concur to form the idea of motion, namely, the space and the time. These are all the circumstances that we observe in a motion. Time elapses, and during its currency a space is described. The term *velocity* expresses the magnitude of the space, which corresponds to some unit of time. Thus the rate of a ship's motion is determined when we say that it is nine miles in an hour, or nine miles per hour. We sometimes say (but awkwardly) "the motion is at the rate or with the velocity of a mile in three days." It is most conveniently expressed by a number of some given units of length, which completely make up the line described during this unit of time. But the mechanicians express it in a way more general by a fraction, of which the numerator is a number of inches, feet, yards, fathoms, or miles, and the denominator is the number of seconds, minutes, or hours employed in moving along this line. This is a very proper expression; for when we speak of any velocity, and continue to reason from it, we conceive ourselves to speak of something that remains the same, in the different occasions of using the term. Now if the velocity be constant, it is indifferent how long the line may be, because the time of its description will be lengthened in the same proportion. Thus if 48 feet be described in 12 seconds, 36 feet will be described in 9 seconds, 16 feet will be described in 4 seconds, &c. Now $\frac{48}{12}$, $\frac{36}{9}$, and $\frac{16}{4}$, are fractions of equal value, being equal to $\frac{4}{1}$, or 4, that is, to the velocity of 4 feet per second. The value of this fraction, or the quotient of the number of the units of length, divided by the number of units of time, is the number of those units of length described uniformly in one unit of time.

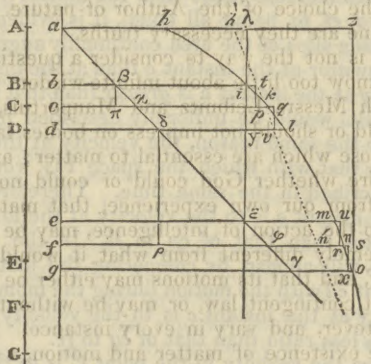
Magnitude of a velocity which we have no actual measure.

But how shall we determine the velocity in any instant or in any point of a motion that is continually changing? Suppose that a body has fallen 144 feet, and that we would ascertain its velocity in that point of its fall, or the velocity which it has in passing through that point. In the next second the body falls 112 feet farther. This cannot be the measure of the velocity at the beginning of the fourth or the end of the third second. It is too great. The fall during the preceding second was 80 feet. This is too small. The mean of these two, or $\frac{80+112}{2}, = \frac{192}{2} = 96$, is probably more exact. Due attention to the nature of this motion shows us that 96 is the proper measure, or that the motion at that instant is at the rate of 96 feet per second. But it is peculiar to this kind of motion that the half sum of the spaces described in two succeeding equal moments is the measure of the velocity in the middle instant. Therefore this method will not generally give an accurate measure. Yet it is indispensably necessary to obtain some accurate measure; for it is in this particular alone that the state of the body differs from its similar state in another instant. The difference of place makes no distinction; for if a body continue its motion unchanged, its condition in every different instant of time, or point of space, is unchanged, or the same. The change of place is not a change of motion, but is involved in the very conception of the continuation of the motion. The change of condition consists, therefore, in the change of velocity: therefore the change of velocity is the only indication and the only measure of the action (perhaps accumulated) of the changing force. It is therefore the chief object of our search; and accurate measures of velocity are absolutely necessary.

Momentary proportion of velocities that are continually changing.

72. When the velocity changes continually, there can be no *actual* measure of it. In what then does the magnitude of a velocity consist, when there is no actual measure of it? It is a certain undescribable *determination*, by which, if not changed, a certain space *would* be uniformly described in a given unit of time. Thus we know, that if, when a stone has fallen sixteen feet, its motion be directed along a horizontal plane, without diminution, it will move on for ever at the rate of thirty-two feet per second. The space which would be thus described is not the velocity, but the measure of the velocity. But the proportions of those spaces, being the proportions of those measures, are the proportions of the velocities themselves. We may discover these proportions in the following manner:

Fig. 15.



Fundamental requisite in all mechanical disquisitions.

Let ACG (fig. 15) be a line described by a body with a motion any how continually but gradually varied; and let it be required to determine the proportion of the velocity in any point C to the velocity in any other point F.

Axiom.—If A be to B in a ratio that is greater than any ratio less than that of C to D, but less than any ratio greater than that of C to D, then A is to B as C to D.

Take the straight line *acg* to represent the time of the body's motion along ACG, so that the points *a*, *c*, *f*, *g*, may represent the instants of time in which the body passes through the points A, C, F, G; and the portions *ac*, *cf*, *fg*, of the line *ag*, may represent the times employed in describing the portions AC, CF, FG; and therefore *ac* is to *af* as the time of describing AC to the time of describing AF.

Of Accelerated and Retarded Motions.

Moreover, let *hkno* be a line so related to the straight line *acfg*, by the perpendicular ordinates *ah*, *ck*, *fn*, *go*, that the areas *ackh*, *afnh*, *agoh*, may be proportional to the portions AC, AF, AG, of the line described by the moving body; and let this relation be true with respect to every point B, D, E, &c. and the corresponding points *b*, *d*, *e*, &c.

Then it is affirmed that *the velocity in the point* C *is to the velocity in the point* F *as ck is to fn.*

Let the equal lines *bc*, *cd*, *ef*, *fg*, represent equal moments of time, and let B, D, E, G, be the points through which the body is passing at the instants *b*, *d*, *e*, *g*. Then the areas *bikc*, *ckld*, *emnf*, *fnog*, will represent, and be proportional to, the spaces BC, CD, EF, FG, which are described during the moments *bc*, *cd*, *ef*, *fg*.

Draw *tp* parallel to *ag*, so as to make the rectangle *btpc* equal to the trapezium *bikc;* and draw the lines *qv*, *ur*, *sx*, in the same manner, so that each rectangle may be equal to its corresponding trapezium.

If the motions had been uniform during the moments *bc* and *fg*, that is, if the spaces BC and FG had been uniformly described, then the velocity in the point C would have been to the velocity in the point F as *cp* to *fs;* for since the rectangles *btpc* and *fsxg* are respectively equal to the trapeziums *bikc* and *fnog*, and since *bikc* is to *fnog* as BC is to FG, the rectangle *btpc* is to the rectangle *fsxg* as BC to FG. But because these two rectangles have equal altitudes *bc* and *fg*, they are to each other in the proportion of their bases *cp* and *gx*, or *cp* and *fs*. Therefore BC is to FG as *cp* to *fs*. But if BC and FG are uniformly described in equal times, they are proportional to the velocities of those uniform motions. Therefore *cp* is to *fs* as the velocity with which BC is uniformly described to the velocity with which FG is uniformly described in an equal time.

But the motion expressed by the figure is not uniform, because the line *hlo* recedes from the axis *ag*, and the areas, cut off by the parallel ordinates, increase in a greater proportion than the corresponding parts of the axis; that is, the spaces increase faster than the times; for the moments *bc*, *cd*, *ef*, *fg*, being all equal, it is evident that the corresponding slips of the area continually augment. The motion is swifter at the instant *c* than at the instant *b*, and the velocity at the instant *c* is *greater* than that with which the space BC would be uniformly described in the same time. For the same reason, the velocity at the instant *f* is *less* than that with which the space FG would be uniformly described in the same time. Therefore the velocity at the instant *c* is to the velocity at the instant *f* in a greater ratio than that of *cp* to *fs*. In the very same manner, it will appear, by comparing the motion during the moment *cd* with the motion during the moment *ef*, that the velocity at the instant *c* is to the velocity at the instant *f* in a less ratio than that of *cq* to *fr*.

Therefore the velocity in the point C is to the velocity in the point F in a greater ratio than that of *cp* to *fs*, but in a less ratio than that of *cq* to *fr*.

But by continually diminishing the equal moments *bc*, *cd*, *ef*, *fg*, it is evident that *cp* and *cq* continually approach to equality with *ck*, and *fr* and *fs* continually approach to equality with *fn;* that when *cp* is less than *ck*, *fs* is greater than *fn*, and when *cq* is greater than *ck*, *fr* is less than *fn*.

Therefore the velocity in the point C is to the velocity in the point F in a ratio that is greater than the ratio of *any* line less than *ck* to *any* line greater than *fn*, but which is less than the ratio of any line greater than *ck* to any line less than *fn*. Therefore the ratio of the velocity in C to the velocity in F is greater than any ratio that is less than that of *ck* to *fn;* but it is less than any ratio that is greater than that of *ck* to *fn*. Therefore the velocity in the point C is to the velocity in the point F as *ck* to *fn*.

This important theorem may be expressed in more general terms as follows:

If the abscissa ag of a line hko represent the time of any motion, and if the areas bounded by parallel ordinates be proportional to the spaces described, the ordinates are proportional to the velocities.

Remark.—The propriety or aptitude of expressing the time by the portions of the axis *acg* will perhaps appear more clearly in the following manner:

Let *acg* be any straight line, and let *h'kv* be another line straight or curved. Let the straight line *ahz*, perpendicular to *ag*, be carried uniformly down along this line, keeping always perpendicular to it, and therefore always parallel to its first position *ahz*. In its various situations *ckz*, *emz*, &c. it will cut off areas *ackh*, *aemh*, &c. bounded by the axis, by the ordinates *ah* and *ck*, or by the ordinates *ah* and *em*, &c. and by the line *hkg*. By this motion the moveable ordinate is said, in the language of modern geometry, to *generate* the areas *ackh*, *acmh*, &c. At the same time, let a point A move along the line ACG, setting out from A at the instant when the line *az* sets out from *a;* and let the motion of the point A be so regulated that the spaces AB, AC, AD, &c. generated by this motion may increase at the same rate with the areas *abih*, *ackh*, *adlh*, &c. or such that we shall have AB to AC as *abih* to *ackh*, &c. It is plain that the motion along AG is the same with that described in the enunciation of the proposition; for because the motion of the ordinate *az* along the axis *ag* is supposed to be uniform, the spaces *ab*, *ac*, *ad*, &c. are proportional to the times in which they are described, and may therefore be taken to measure or to represent those times.

73. Cor. 1. *In a motion continually varied, the velocities in the different points of the path are to each other in the limiting or ultimate ratio of the spaces described in equal times,* those times being supposed to diminish continually; for it is evident that if the equal moments *bc*, *cd*, *ef*, *fg*, are supposed to diminish continually till the instants *b* and *d* coalesce with *c*, and the instants *e* and *g* coalesce with *f*, then the ratio of *ck* to *fn* is the limit of the continually increasing ratio of *cp* to *fs*, or of the continually diminishing ratio of *cq* to *fr*. Sir Isaac Newton calls this the ultimate ratio of *cp* to *fs*, or of *cq* to *fr*. Now the ratio of *cp* to *fs* is, by construction, the same with the ratio of the rectangle *btpc* to the rectangle *fsxg*, and the ratio of *cq* to *fr* is the same with the ratio of the rectangle *cqvd* to the rectangle *eurf*. But the ratio of the rectangle *btpc* to the rectangle *fsxg* is the same with the ratio of the space *bikc* to the space *fnog;* that is (by hypothesis) the same with the ratio of the space BC to the space FG; and the ratio of the rectangles *cqvd* and *eurf* is the same with that of the spaces CD and EF. Therefore the ratio of the velocity at C to the velocity at F is the same with the ultimate ratio of the small increments BC, FG, or CD, EF of the spaces generated in very small and equal times.

It is also evident, that because the ratio of *ck* to *fn* is the limit both of the ratio of *cp* to *fs* and of the ratio of *cq* to *fr*, these ultimate ratios are the same, and that we may say that the velocity in C is to the velocity in F in the ultimate ratio of BC to EF, or in the ultimate ratio of CD to FG.

We also can easily perceive that the ratio of the area *bikc* to the area *emnf* approaches more near to the ratio of *ck* to *fn* as we take the moments *bc* and *ef* smaller. Therefore, in many cases of practice, where it may be easy to measure the spaces described in the different small moments of the motion, but difficult to ascertain their ultimate ratio, so as to obtain accurate measures of

Of cele- rat and Re ded M ons.

the proportions of the velocities, we may reduce the errors of measurement to something very insignificant, by taking these moments extremely small; and we shall diminish the error still more by taking the proportion of the half sum of BC and CD to the half sum of EF and FG for the proportion of the velocities in C and F.

It often happens that we have it not in our power to compare the spaces described in small moments which are precisely equal. Still we can find the exact proportion of the velocities, if we can ascertain the ultimate ratio of the increments of the spaces, and the ultimate ratio of the moments of time in which these increments are described; for it is plain, by considering the gradual approach of the points p and r to the points k and n, that the ratio of ck to fn is still the ultimate ratio of the bases of rectangles equal to the mixtilineal areas, whether the altitudes (representing the moments) are equal or not. Now the bases of two rectangles are in the proportion of the rectangles directly, and of their altitudes inversely. But the ultimate ratio of the altitudes is the ultimate ratio of the moments, and the ultimate ratio of the rectangles is the ultimate ratio of the spaces described in those unequal moments. Therefore, in such cases, we have,

74. Cor. 2. *The velocities are in the ratio compounded of the direct ultimate ratio of the momentary increments of the spaces, and the inverse ultimate ratio of the increments (or moments) of the times in which these increments of the spaces are made.*

If s, v, and t, are taken to represent the magnitudes of the spaces, velocities, and times, and if ds, dt, and dv, are taken always in the limiting or ultimate ratio of their momentary increments,[1] we shall have v always in the proportion of ds directly, and of dt inversely. We express this by the proportional equation $v \doteqdot \frac{ds}{dt}$, which is equivalent to the analogy $\mathrm{V} : v = \frac{d\mathrm{S}}{d\mathrm{T}} : \frac{ds}{dt}$, or $\mathrm{V} : v = d\mathrm{S}dt : dsd\mathrm{T}$.

75. N. B. Here observe that this is not the only way of stating the relation of space and time—the abscissa may be made the time, and the ordinate the space: then the velocity $= \frac{dy}{dx}$.

The converse of this proposition may be thus expressed.

C erse th rem.

76. *If the axis ag of the line hko represent the time of a varied motion along the line* AG, *and if the ordinates ah, bi, ck, &c. be as the velocities in the instants a, b, c, or in the points* A, B, C; *then the areas abih, ackh, adlh, &c. are proportional to the spaces* AB, AC, AD, &c.

This may be demonstrated in the same way with the former; but the indirect demonstration is more brief, and equally strict.

If the spaces AC, AF, &c. are not proportional to the areas $ackh$, $afnh$, &c. they are proportional to some other areas $ackh'$, $afn'h'$, &c. which are bounded by the same ordinates, and by another line $h'kn'$. But because the areas $ackh'$, $afn'h'$, &c. are always proportional to the spaces AC, AF, &c. described on the line AG, the velocity in the point C is to the velocity in the point F as the ordinate ck is to the ordinate fn'; but, by hypothesis, the velocity in C is to the velocity in F as ck to fn, and fn' is equal to fn, which is absurd. Therefore the spaces AC, AF, are not proportional to any other areas, &c.

Of Accelerated and Retarded Motions.

77. Cor. *The ultimate ratio of the momentary increments of the spaces is compounded of the ratio of the velocities, and the ultimate ratio of the increments of the times:* for when the moments bc, ef, are equal, it is evident that the ultimate ratio of the rectangles $bcpt$, $efru$ is the same with the ultimate ratio of the increments of the spaces. But the ultimate ratio of these rectangles is the same with that of their bases cp and fr; that is, the ratio of ck to fn, that is, the ratio of the velocities. And when the moments are unequal, the ratio of the rectangles is compounded of the ratio of their bases and the ratio of their altitudes; that is, compounded of the ratio of the velocities and the ultimate ratios of the moments of time.

We have therefore $d\mathrm{S} : ds = \mathrm{V}d\mathrm{T} : vdt$ and $ds \doteqdot vdt$.

It most commonly happens that we can only observe the accumulated results of varied motions, and in them we only observe a space passed over, and a certain portion of time that has elapsed during the motion; but being able to distinguish the portions of the whole space which are described in known portions of the whole time, and having made such observations in several parts of the motion, we discover the general law that the motion affects, and we affirm this law to hold universally, even though we have not observed it in *every* point. We do this with a degree of probability and confidence proportioned to the frequency of our observation. It is not till we have done this that we can make use of the first of these two propositions, which enables us to ascertain the velocity of the motion in its different moments. Thus, if we observe that a stone in falling descends one foot in the quarter of a second, 16 feet in a second, 64 feet in two seconds, and 144 feet in three seconds, the general law immediately observed is, "that the spaces described are as the squares of the times;" for 1 is to 16 as the square of $\frac{1}{4}$ to the square of 1. Again, 16 is to 64 as 1^2 to 2^2, and 16 is to 144 as 1^2 to 3^2. Hence we infer, with great probability, that the stone would fall 36 feet in a second and a half; for 16 is to 36 as 1^2 to $1\frac{1}{2}^2$; and we conclude in the same way for all other parts of the motion.

A good example of geometrical method.

78. This immediate observation of the analogy between the spaces and the squares of the times suggests an easy determination of the velocity in this particular kind of motion, and it merits particular notice, being very often referred to. We can take ag to represent the time, and then, because the areas which are to represent the spaces described must be proportioned to the squares of the portions of ag, we perceive that the line which comes in place of hko must be a straight line drawn from a; for example, the straight line $a\delta\gamma$; for this is the only boundary which will give areas $ab\beta$, $ae\varkappa$, $ad\delta$, &c. proportional to ab^2, ae^2, ad^2, &c. And we perceive that *any* straight line drawn from a will have this property.

Having thus got our representations of the times and the spaces, we say, on the authority of our theorem, that the velocity at the instant b is to the velocity at the instant d as $b\beta$ to $d\delta$, &c. And now we begin to make inferences purely geometrical, and express our discovery of the velocities in a very general and simple manner. We remark, that $b\beta$ is to $d\delta$ as ab is to ad; and we make the same affirmation concerning the magnitudes represented by these lines. We say that the velocity at the instant b is to the velocity at the instant d as the time ab is to the time ad. We say, in terms still more general, that the velocities are proportional to the times from the beginning of the motion. We moreover perceive, that the spaces are

---

[1] In this article, as originally printed, the symbols $\dot{s}$, $\dot{t}$, and $\dot{v}$ were employed to represent the things here denoted by ds, dt, and dv: a like change in the notation of the fluxions of the quantities will be made throughout the article.

Of Accelerating and Retarding Forces.

also proportional to the squares of the acquired velocities; or the velocities are as the square roots of the spaces.

We can further infer, from the properties of the triangle, that the momentary increments of the spaces are proportional to the momentary increments of the squares of the times, or of the squares of the velocities.

We also observe, that not only the whole acquired velocities are proportional to the whole elapsed times, but that the increments of the velocities are proportional to the times in which they are acquired; for πn is to $\varrho\varphi$ as bc to df, &c. Equal increments of velocity are therefore acquired in equal times. Therefore such a motion may, in great propriety of language, be denominated a *uniformly accelerated motion;* that is, *a motion in which we observe the spaces proportioned to the squares of the times, is a motion uniformly accelerated;* and spaces in the duplicate ratio of the times form the ostensible characteristic of an uniformly accelerated motion.

79. Lastly, if we draw $\varepsilon\lambda$ parallel to the axis ab, we perceive that the rectangle $ae\varepsilon\lambda$ is double of the triangle $ae\varepsilon$. Now, because ae represents the time of the motion, and $e\varepsilon$ represents the acquired velocity, the rectangle $ae\varepsilon\lambda$ will represent the space which would be uniformly described with the velocity $e\varepsilon$ during the time ae. But the triangle $ae\varepsilon$ represents the space really described with the uniformly accelerated motion during the same time. Hence we infer, that the space that is described in any time, with a motion increasing uniformly from nothing, is one half of the space which would be uniformly described during the same time with the final velocity.

These are but a part of the inferences which we may draw from the geometrical properties of those representations which we had selected of the different measureable affections of motion. We may affirm, with respect to the motions themselves, all the inferences which relate to magnitude and proportion, and thus improve our knowledge of the motions.

We took the opportunity of this very simple and perspicuous example, to give our readers a just conception of the *mathematical method* of prosecuting mechanical knowledge, and to make them sensible of the unquestionable authority for every theorem deduced in this manner.

One of the most important is, to discover the accumulated result of a motion of which we only observe the momentary increments. This is to be done by finding the area, or portions of the area, of the mixtilineal space $agoh$; and it is evidently analogous to the inverse method of fluxions, or the integral calculus.

In most cases, we must avail ourselves of the corollary $ds \doteq vdt$, and we obtain the solution of our question only in the cases where our knowledge of the quantities ds, dt, and v (considered as geometrical magnitudes, that is, as lines and surfaces), enables us to discover s and t.

OF ACCELERATING AND RETARDING FORCES.

80. Having thus discovered the proportions of the velocities in motions varying in any manner whatever, we can observe the variations which happen in them. These variations are the effects, and the only marks and measures, of the changing forces. They are the characteristics of their kinds (considered merely as moving forces); that is, the indications of the directions in which they act; for this is the only difference *in kind* of which they are susceptible in this general point of view. If they increase the velocity, their direction must be conceived as the same with that of the previous motion; because the result of the action of a force is equivalent to the composition of the motion which that force would produce in a quiescent body with the motion already existing; and an increase of velocity is equivalent to the composition of a motion in the same direction.

Having no other mark of the force but the acceleration, we have no other name for it in the abstract doctrines of dynamics, and we call it an *accelerating force.* Had it retarded the motion, we should have called it a *retarding force.*

In like manner we have no measure of the *magnitude* or *intensity* of an accelerating force, but the acceleration which it produces. In order therefore to investigate the powers which produce all the changes of motion, we must endeavour to obtain measures of the acceleration.

A continual increase of velocity is the effect of the continued action of accelerating forces. If equal increments of velocity are produced in every succeeding equal moment of time, we cannot conceive that there is any change in the accelerating force. Therefore a uniformly accelerated motion is the mark of the unvaried action of an accelerating force, that is, of the continued action of a constant force; of a force whose intensity is always the same. When therefore we observe a body describe spaces proportional to the squares of the times, we must infer that it is urged forward by a force whose intensity does not change; and, on the other hand, a constant force must produce a uniformly accelerated motion by its continued action. And if any previous circumstances assure us of this continued action of an invaried force, we may make all the inferences which were mentioned under the article of uniformly accelerated motion.

Meas of an acc rating force.

81. That force must surely be accounted double which produces a double increment of velocity in the same time by its uniform action; we can form no other estimation of its magnitude. And in general, *accelerating forces must be accounted proportional to the increments of velocity which they produce, by acting uniformly during the same or equal times.*

Anoth measu

Supposing them to act on a body at rest. Then the velocity produced is itself the increment; and we must say that accelerating forces are proportional to the velocities which they generate in a body in equal times. And because we found (No. 79), that the space described with a uniformly accelerated motion is half the space which would be uniformly described in the same time with the final velocity, which space is the direct measure of this velocity, and because halves have the same proportion with the wholes—we may say that *accelerating forces are proportional to the spaces through which they impel a body from rest in equal times by their uniform action.*

This is an important remark; because it gives us an easy measure of the force, without the trouble of first computing the velocities. It also gives us the only distinct notion that we have of the measurement of forces by the motions which they produce. When speaking of the composition of forces, we distinguished or denominated them by the sides and diagonal of a parallelogram. These lines must be conceived as proportional to the spaces through which the forces urge the body *uniformly* during the small and insensible time of their action, which time is supposed to be the same for both forces; for the sides of the parallelogram are supposed to be separately described in equal times, and therefore to be proportional to the velocities generated by the constituent forces. If indeed the forces do not act uniformly, nor similarly, nor during equal times, we cannot say (without farther investigation) what is the proportion of the intensity of the forces, nor can we infer the composition of their action. We must at least suppose, that in every instant of this very small time of their joint action, their direction remains unchanged, and that their intensities are in the

O Accele- ing and R arding rces.

same ratio. We shall see by and by, that with these conditions the sides of the parallelogram are still proportional to the velocities generated. In the mean time we may take the spaces through which a body is uniformly impelled from rest (that is, with a uniformly accelerated motion) as the measures of the forces; yet these spaces are but the halves of the measures of the velocities. Then, if a body be moving with the velocity of thirty-two feet per second, and an accelerating force acts on it during a second, and if this force be such that it would impel the body (from a state of rest) sixteen feet, it will add to the body a velocity of thirty-two feet per second. Accordingly, this is the effect of gravity—the weight of a pound of lead may be considered as a force which does not vary in its intensity. We know that it will cause the lead to fall sixteen feet in a second; but if the body has already fallen sixteen feet, we know that it is then moving with the velocity of thirty-two feet per second. And the fact is, that it will fall forty-eight feet farther in the next second, and will have acquired the velocity of sixty-four feet per second. It has therefore received an augmentation of thirty-two feet of velocity by the action of gravity during the second second; and gravity is in fact a constant force, causing equal increments of velocity in equal times, however great the velocities may be. It does not act like a stream of fluid, whose impulse or action diminishes as the solid body withdraws from it by yielding.

But supposing that we have not compared the increments of velocity uniformly acquired during equal times, in what manner shall we measure the accelerating forces? In such a case that force must be accounted double which generates the same velocity, by acting uniformly during half the time; for when the force is supposed invariable, the changes of velocity which it produces are proportional to the times of its action; therefore if it produces an equal velocity in half the time, it will produce a double velocity in an equal time, and is therefore a double force. The same may be said of every proportion of time in which an equal change of velocity is produced by the uniform action of an accelerating force. The force must be accounted greater in the same proportion that the time required for the production of a given velocity in a body is less. Hence we infer that *accelerating forces are inversely proportional to the times in which a given change of velocity is produced by their uniform action.*

82. By combining these two propositions, we establish this general theorem:

M sure of a lerat- i force.

Accelerating forces are proportional to the changes of velocity which they produce in a body by their uniform action directly, and to the times in which these changes are produced inversely.

If, therefore, A and a are the forces, V′ and v' the changes of velocity, and T′ and t' the portions of time in which they are uniformly produced, we have

$$A : a = V't' : v'T', = \frac{V'}{T'} : \frac{v'}{t'}$$

$$\text{and } a \doteqdot \frac{v'}{t'}.$$

The formula $a \doteqdot \frac{v'}{t'}$ is not restricted to any particular magnitude of v' and t'. It is true, therefore, when the portion of time is diminished without end; for since the action is supposed uniform, the increment of velocity is lessened in the same proportion, and the value of the fraction $\frac{v'}{t'}$ remains the same. The characters or symbols v' and t' are commonly used to express *finite* portions of v and t. The symbols $\dot{v}$ and $\dot{t}$ are used by Newton to express the same things taken in the ultimate or limiting ratio. (These have been changed to dv and dt throughout this article.) They are usually considered as *indefinitely small* portions of v and t. We shall abide by the formula $a \doteqdot \frac{dv}{dt}$.

Of Accelerating and Retarding Forces.

Is an abstract number.

83. It must always be kept in mind, that v and t are abstract numbers; and that v refers to some unit of space, such as a foot, an inch, a yard; and that t refers to some unit of time, such as an hour, a minute, a second; and especially that a is the number of the same units of space, which will be uniformly described in *one* unit of the time with the velocity generated, by the force acting uniformly during *that* unit. It is twice the space actually described by the body during that unit when impelled from rest by the accelerating force. It is necessary to keep hold of these clear ideas of the quantities expressed by the symbols.

Measure of a change of velocity.

On the other hand, when the measure of the accelerating force is previously known, we employ the theorem $at = v'$; that is, the addition made to the velocity during the whole or any part of the time of the action of the force is obtained by multiplying the acceleration of one unit of time by the number of such units contained in t'.

These measures express the greatest part of our knowledge of mechanical nature.

These are evidently leading theorems in dynamics, because all the mechanical powers of nature come under the predicament of accelerating or retarding forces. It is the collection of these in any subject, and the manner in which they accompany or are inherent in it, which determine the mechanical character of that subject; and therefore the phenomena by which they are brought into view are the characteristic phenomena. Nay, it may even be questioned whether the phenomena bring any thing more into view. This force, of which we speak so familiarly, is no object of distinct contemplation; it is merely a something that is proportional to $\frac{dv}{dt}$. And when we observe that the $\frac{dV}{dT}$, found in the motions that result from the vicinity of a body A, is double of the $\frac{dv}{dt}$ which results from the vicinity of another body B, we say that a force resides in A, and that it is double of the force residing in B. The accelerations are the things immediately and truly expressed by these symbols. And the whole science of dynamics may be completely taught without once employing the word *force*, or the conception which we imagine that we form of it. It is of no use till we come to study the mechanical history of bodies. Then, indeed, we must have some way of expressing the fact, that an acceleration $= \frac{32 \text{ feet}}{1''}$ is observed in every thing on the surface of this globe; and that an acceleration $= \frac{418 \text{ feet}}{1''}$ is observed over all the surface of the sun. These facts are characteristic of this earth and of the sun; and we express them shortly by saying that such and such forces reside in the earth and in the sun. It will preserve us from many mistakes and puzzling doubts, if we resolutely adhere to this meaning of the term *force;* and this will carry mathematical evidence through the whole of our investigations.

Another measure of accelerating force.

84. As velocity is not an immediate object of contemplation, and all that we observe of motion is a space and a time, it may be proper to give an expression of this measure of accelerating force which involves no other idea. Supposing the body to have been previously at rest, we

Of Accelerating and Retarding Forces.

have $a \doteqdot \frac{v}{t}$. Multiply both parts of the fraction by t which does not change its value, and we have $a \doteqdot \frac{vt}{t^2}$. But $vt = s$; and therefore $a \doteqdot \frac{s}{t^2}$.

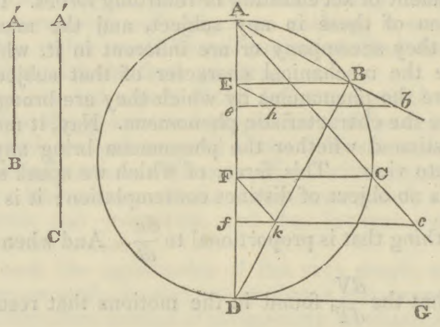
The formula $a = \frac{s}{t^2}$ is equivalent to the proportion $t^2 : 1 = s : a$; and a would then be the space through which the accelerating force would impel the body in one unit of the time t. But this is only half of the measure of the velocity which the accelerating force generates during that unit of time. For this reason we did not express the accelerating force by an ordinary equation, but used the symbol $\doteqdot$. In this case, therefore, of uniform action, we may express the accelerating force by $a = \frac{2s}{t^2}$.

85. The following theorem is of still more extensive use in all dynamical disquisitions.

Most general measure of accelerating force.

Accelerating forces are proportional to the momentary increments of the squares of the velocities directly, and as the spaces along which they are uniformly acquired inversely.

Fig. 16.



Let A'B, A'C, and AD (fig. 16) be three lines, described in the same or equal times by the uniform action of accelerating forces; the motions along these lines will be uniformly accelerated, and the lines themselves will be proportional to the forces, and may be employed as their measures. On the greatest of them, AD, describe the semicircle ABCD, and apply the other two lines A'B, A'C as chords AB, AC. Draw EB, FC perpendicular to AD. Take any small portions B*b*, C*c* of AB and AC, and draw *be*, *cf* perpendicular to AD, and E*h* and F*k* parallel to AB and AC.

Then, because the triangles DAB and BAE are similar, we have $AD : AE = AD^2 : AB^2$. And because AD is to AB as the velocity generated at D is to the velocity generated at B (the times being equal), we have AD to AE as the square of the velocity at D to the square of the velocity at B; which we may express thus:

$$AD : AE = V^2, D : V^2, B.$$

For the same reasons we have also

$$AD : AF = V^2, D : V^2, C. \text{ Therefore}$$
$$AE : AF = V^2, B : V^2, C.$$

But because in any uniformly accelerated motion, the spaces are as the squares of the acquired velocities, we have also

$$AE : Ae = V^2, B : V^2 b, \text{ and}$$
$$AF : Af = V^2, C : V^2 c.$$

Therefore E*e* is to F*f* as the increment of the square of the velocity acquired in the motion along B*b* to the increment of the square of the velocity acquired along C*c*.

But by similarity of the triangles ABD and E*eh*, we have

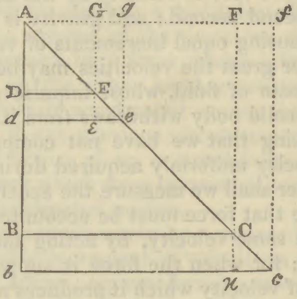
$$AB : AD = Ee : Eh; \text{ and in like manner,}$$
$$AD : AC = Fk : Ff. \text{ Therefore}$$
$$AB : AC = Ee \times Fk : Ff \times Eh.$$

Now AB and AC are proportional to the forces which accelerate the body along the lines A'B and A'C; E*e* and F*f* are proportional to the increments of the squares of the velocities acquired in the motions along the portions B*b* and C*c*; and E*h* and F*k* are equal to those portions respectively. The ratio of AB to AC is compounded of the direct ratio of E*e* to F*f*, and the inverse ratio of E*h* to F*k*. The proposition is therefore demonstrated.

The proportion may be expressed thus:

$AB : AC = \frac{Ee}{Eh} : \frac{Ff}{Fk}$, and may be expressed by the proportional equation $AB \doteqdot \frac{Ee}{Eh}$, or symbolically, $a \doteqdot \frac{d(v^2)}{ds}$.

Fig. 17.



REMARK.—Because the motion along any of these three lines is uniformly accelerated, the relation between spaces, times, and velocities, may be represented by means of the triangle ABC (fig. 17); where AB represents the time, BC the velocity, and ABC the space. If BC be taken equal to AB, the triangle is half of the square ABCF of the velocity BC; and the triangle ADE is half of the square ADEG of the velocity DE. Let D*d* and B*b* be two moments of time, equal or unequal. Then D*de*E and B*bc*C are half the increments of the squares of the velocities DE and BC, acquired during the moments D*d* and B*b*. It was demonstrated that the ratio of the area D*de*E to the area B*bc*C is compounded of the ratio of DE to BC, and the ultimate ratio of D*d* to B*b*. But D*d* and B*b* are respectively equal to ε*e* and κ*c*. Therefore D*de*E is to B*bc*C, in the ratio compounded of the ratio of DE to BC, and the ultimate ratio of ε*e* to κ*c*. If we represent DE and BC by V and v, then ε*e* and κ*c* must be represented by V' and v', the increments of V and v; and then the compound ratio will be the ratio of VV' to vv'; and if we take the ultimate ratio of the moments, and consequently the ultimate ratio of the increments of the velocities, we have the ratio of VdV to vdv. If therefore V^2 and v^2 represent the squares of the velocities, VdV and vdv will represent, not the increments of those squares, but half the increments of them.

We may now represent this proposition concerning accelerating forces by the proportional equation $a \doteqdot \frac{vdv}{ds}$; and we must consider this as equivalent with $a = \frac{V^2 - v^2}{2(S-s)}$; keeping always in mind that a, V, and v, relate to the same units of time and space, and that a is that number of units of the scale on which S and s are measured, which is run over in *one* unit of time.

This will be more clearly conceived by taking an example. Let us ascertain the accelerative power of gravity, supposing it to act uniformly on a body. Let the spaces be measured in feet and the time in seconds. It is a matter of observation, that when a body has fallen 64 feet, it has acquired a velocity of 64 feet per second; and that when it has fallen 144 feet, it has acquired the velocity of 96 feet per second. We want to determine what velocity gravity communicated to it by acting on it during one second. We have $V^2=9216$, and $v^2=4096$; and therefore $V^2-v^2=5120$. $S=144$, and $s=64$, and $S-s=80$, and $2(S-s)=160$. Now $a=\frac{5120}{160},=32$. Therefore gravity has generated the velocity 32 feet per second by acting uniformly during one second.

86. *The augmentation of the square of the velocity is proportional to the force and to the space jointly.* For, because $a=\frac{vdv}{ds}$, we have $ads=vdv$.

Thus we learn, that a given force, acting uniformly on a body along a given space, produces the same increment of the square of the velocity, whatever the previous velocity may have been. Also, in the same manner as we formerly found that the augmentation of the velocity was proportioned to the time during which the force has acted, so the augmentation of the square of the velocity is proportional to the space along which it has acted.

It is pretty plain, that all that we have said of the uniform action of an *accelerating* force may be affirmed of a *retarding* force, taking a diminution or decrement of velocity in place of an increment. A uniformly retarded motion is that in which the decrements of velocity in equal terms are equal, and the whole decrements are proportional to the whole times of action. Such a motion is the indication of a constant or invariable force acting in a direction opposite to that of the motion. We conceive this to be the case, when an arrow is shot perpendicularly upwards; its weight is conceived as a force continually pressing it perpendicularly downwards.

In such motions, however great the initial velocity may be, the body will come to rest; because a certain determined velocity will be taken from the body in each equal successive moment, and some multiple of this will exceed the initial velocity. Therefore the velocity will be extinguished before the end of a time that is the same multiple of the time in which the velocity was diminished by the quantity above mentioned. It is no less evident that the time in which any velocity will be extinguished by an opposing or retarding force, is equal to the time in which the same force would generate this velocity in the body previously at rest. Therefore,

87. (1.) The times in which different initial velocities will be extinguished by the same opposing force are proportional to the initial velocities.

88. (2.) The distances to which the body will go till the extinction of its velocity, are as the squares of the initial velocities.

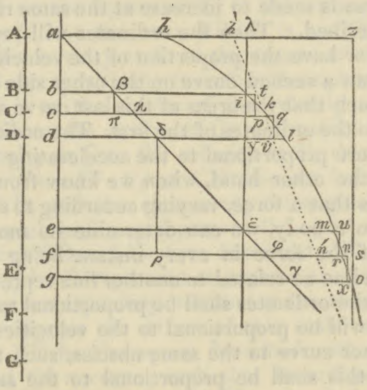
(3.) They are also as the squares of the times elapsed.

89. (4.) The distance to which a body, projected with any velocity, will go till its motion be extinguished by the uniform action of a retarding force, is one half of the space which it would describe uniformly during the same time with the initial velocity.

It very rarely happens that the force which accelerates the body acts uniformly, or with an unvaried intensity. The attraction of a magnet, for example, increases as the iron approaches it. The pressure of a spring diminishes as it unbends. The impulse of a stream of water or wind diminishes as the impelled surface retires from it by yielding. Therefore the effects of accelerating forces are very imperfectly explained, till we have shown what motions result from any given variation of force, and how to discover the variation of force from the observed motion. This last question is perhaps the most important in the study of mechanical nature. It is only thus that we learn what is usually called *the nature of a mechanical force.* This chiefly consists in the relation subsisting between the intensity of the force and the distance of the substance in which it resides. Thus the nature of that power which produces all the planetary motions, is considered as ascertained, when we have demonstrated that its pressure or intensity is inversely as the square of the distance from the body in which it is supposed to reside.

Acceleration expresses some relation of the velocity and time. This relation may be geometrically expressed in a variety of ways. In fig. 18 the uniform acceleration, or the unvaried relation between the velocity and the time, is very aptly expressed by the constant ratio of the ordinates and abscisses of the triangle *agγ*. The ratio of *dδ* to *ad* is the same with that of *eε* to *ae*, or that of *fφ* to *af*, &c.; or the ratio of the increment of velocity $\pi\varkappa$ to the increment of the time $\beta\pi$ or *bc*, or that of $\iota\varphi$ to $\varepsilon\iota$, &c. This ratio $\pi\varkappa : \beta\pi$ is equivalent to the symbol $\frac{dv}{dt}$.

Fig. 18.



But when the spaces described in a varied motion are represented by the areas bounded by a curve line *hko*, we no longer have that constant ratio of the increments of the ordinates and abscisses.

Their measures in such cases how obtained. Theorems of most extensive use.

90. Therefore, in order to obtain measures of the accelerating forces, or at least of their proportions, let the abscissa *aeg* (fig. 18) of the line *hko* again represent the time of a motion. But let the areas bounded by parallel ordinates now represent the velocities; that is, let the whole area increase during the time *ag* at the same rate with the velocities of the motion along the line AG. In this case the ordinates *bi*, *ck*, *dl*, &c. will be as the accelerations at the instants *b*, *c*, *d*, &c. or in the points B, C, D, &c.

This is demonstrated in the same way as the former proposition (No. 72). If the accelerating force be supposed constant during any two equal moments *bc* and *fg*, the rectangles *bcpt* and *fgxs* would express the increments of velocity uniformly acquired in equal times, and their bases *cp* and *fs* would have the ratio of the accelerations, or of the accelerating forces. But as the velocities expressed by the figure increase faster than the times during every moment, the force at the instant *c* is to the force at the instant *f* in a greater ratio than that of *cp* to *fs;* but, for similar reasons, it is in a less ratio than that of *cq* to *fr;* and therefore (as in the other proposition) the force at the instant *c* is to the force at the instant *f* as *ck* to *fu*.

91. *Cor.* Because *cp* is to *fs* in the ratio compounded of

Of Accelerating and Retarding Forces.

the direct ratio of the rectangle *cptb* to the rectangle *fsxg*, and the inverse ratio of the altitude *bc* to the altitude *fg*; and because these rectangles are proportional to the increments of velocity, and the ultimate ratio of the altitudes is the ultimate ratio of the moments or increments of the time, we must say that *the accelerating forces (that is, their intensities or pressures producing acceleration) are directly as the increments of velocity, and inversely as the increments of the times;* which proposition may be expressed in regard to two accelerations A and *a*, by this analogy:—

$$A : a = \frac{dV}{dT} : \frac{dv}{dt}.$$

Or by the proportional equation $a \doteqdot \frac{dv}{dt}$. Also $adt \doteqdot dv$, and $\int adt = v'$. And thus do these theorems extend even to the cases where there cannot be observed an immediate measure either of velocity or of acceleration, because neither the space nor the velocity increases uniformly.

The theorem $a \doteqdot \frac{dv}{dt}$ is employed when we would discover the variation in the intensity of some natural power.[1] We observe the motion, and represent it by a figure analogous to fig. 18, where the abscissa represents the times, and the area is made to increase at the same rate with the spaces described. Then the ordinates will represent the velocities, or have the proportion of the velocities. Then we may draw a second curve on the other side of the same abscissa, such that the areas of this last curve shall be proportional to the ordinates of the first. The ordinates of this last curve are proportional to the accelerating forces.

92. On the other hand, when we know from other circumstances that a force, varying according to some known law, acts on a body, we can determine its motion. The intensity of the force in every instant being known, we can draw a line so related to another line representing the time, that the ordinates shall be proportional to the forces. The areas will be proportional to the velocities. We can draw another curve to the same absciss, such that the ordinates of this shall be proportional to the areas of the other, that is, to the velocities of the motion. The areas of this second curve will be proportional to the spaces described.

All these theorems relate to *changes* of velocity; by which means they indicate *immediately* the operation of natural powers.

93. We must now observe, that all that has been said concerning the effects of accelerating forces continually varying, relates to *changes* of motion, independent of what the absolute motions may be. The areas of the line whose ordinates represent the velocities do not necessarily represent the spaces described, but the change made on the spaces described in the same time; not the motions, but the changes of motion. If, indeed, the body be supposed to be at rest when the forces begin to act, these areas represent the very spaces that are passed over, and the ordinates are the very velocities. In every case, however, the accelerations are the real increments of the velocities.

This circumstance gives a great extension to our theorems, and enables us to ascertain the disturbances of any species of regular motion, apart from the motions themselves, and thus avoid a complication which would frequently be inextricable in any other way. And this process, which is merely mathematical, is perfectly conformable to mechanical principles. It is in fact an application of the doctrine of the composition of motion; a doctrine rigidly demonstrated when we measure a mechanical force by the *change* of motion which it produces. Acceleration is the continual composition of a new motion with the motion already produced.

No fi chang veloc can b duced instar any a rating force.

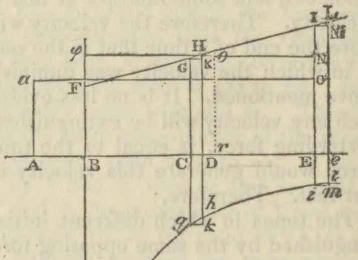
We may learn from this investigation of the value of an accelerating force, that no finite change of velocity is effected in an instant by the action of an accelerating force. When the fig. 18 is used for the scale of accelerations, and they are represented by the ordinates of the line *hko*, the increment of velocity is represented by an area, that is, by a slip of the whole area; which slip must have some altitude, or must occupy some portion of the abscissa which represents time. Some portion of time, however small it may be, must elapse before any measurable addition can be made to the velocity. The velocity must change *continually*. As no motion can be conceived as instantaneous, because this would be to conceive that in one instant the moving particle is in every point of its momentary path,—so no velocity can change, by a finite quantity, in one instant, because this would be to conceive that in that instant the particle had all the intervening velocities. The instant of change is at once the last instant of the preceding velocity, and the first of the succeeding, and therefore must belong to both. This cannot be conceived, or is absurd. As a body, in passing from one part of space to another, must pass in succession through all the intermediate places; so, in passing from one velocity to another, it must in succession have all the intermediate velocities. It must be *continually* accelerated—we must not say *gradually*—however small the steps.

But to return from this digression:

More venien manne consid ing th tion of forces, more f quentl coming into vi

94. The most frequent cases which come under examination do not show us the relation between the forces and times, but the relation between the forces and spaces. Thus, when a piece of iron is in the neighbourhood of a magnet, or a planet is considered in the neighbourhood of the sun, a force is acting on it in every point of its path, and we have discovered that the intensity of this force varies in a certain proportion. Thus, a spring varies in its pressure as it unbends; gunpowder presses less violently as it expands, &c. &c.

Fig. 19.



Our knowledge is generally confined to some such effect as this. We know, that while a body is moving along a line, ADE (fig 19), it is urged forward by a force, of which the intensity varies in the proportion of the ordinates BF, CG, DH, EI, &c. of the line FGHI.

To investigate the motion or change of motion produced by the action of this force, let CD be supposed a very small portion of the space *s*, which we may express by *s'*. Draw GK perpendicular to DH. Then, if we suppose that the

---

[1] See Barrow's *Lect. Geometr.* passim.

O ccele- ra g and R rding rces.

force acts with the unvaried intensity CG through the whole space CD, the rectangle CDKG will express half of the increment of the square of the velocity (No. 85). We may suppose that the force acts uniformly along the adjoining small space Dr with the intensity DH. The rectangle DHor will in like manner express another half increment of the square of the velocity. And in like manner we may obtain a succession of such increments. The aggregate or sum of them all will be half the difference between the square of the velocity at B and the square of the velocity at E.

If we employ f to express the indetermined or variable intensity of the accelerating force, and v to express the variable velocity, and v' its increment *uniformly* acquired, then the rectangle CDKG will be expressed by fs'. We have seen that this is equal to vv'. Therefore, in every case where we can tell the aggregate of all the quantities fs, it is plain that we will obtain half the difference between the squares of the velocities in B and E, on the supposition that the intensity of the force was constant along each little space, and varied by starts. Then, by increasing the number and diminishing the magnitude of those little portions of the space without end, it is evident that we terminate in the expression of the real state of the case, *i. e.* of a force varying continually; and that in this case the aggregate of these rectangles occupies the whole area AEIF, and is equivalent to the fluent of fds, or to the symbol $\int fds$, used to express this fluent, which is conceived an aggregate of small rectangles fs'. And we see that this area expresses half of the augmentation of the square of the velocity. Therefore,

st im- tant orem.

95. *If the abscissa* AE (fig. 19) *of a line* FGI *is the path along which a body is urged by an accelerating force, and if the ordinates* BF, CG, DH, *&c. are proportional to the forces acting in the points* B, C, D, *&c. the intercepted areas* BCGF, BEIF, *&c. are proportional to the augmentations of the square of the velocity.*[1]

Observe that the areas BCGF and DEIH are also proportional to the augmentations made on the squares of the velocities in B and in D.

Observe also, that it is indifferent what may have been the original velocity. The action of the forces represented by the ordinates make always the same addition to its square; and this addition is half the square of the velocity which those forces would generate in the body by impelling it from rest in the point A.

96. Lastly, on this head, observe, that we can state what constant or variable force will make the same augmentation of the square of the velocity by impelling the body uniformly along the same space BE, or along what space a given force must impel the body in order to produce the same increase of the square of its velocity. In the first case, we have only to make a rectangle BENφ, equal to the area BEIF, and then Bφ is the intensity of the constant force wanted. In the second case, in which the force EO is given, we must make the rectangle AαOE equal to the area BEIF, and AE is the space required.

nverse.

97. The converse of this proposition, viz. *if the areas are as the increments of the square of the velocity, the ordinates are as the forces*, is easily demonstrated in the same way; for if the elementary areas CDKG and EIMe represent increments of the squares of the velocity, the accelerating forces are in the ratio compounded of the direct ratio of these rectangles and the inverse ratio of their altitudes, because these altitudes are the increments of the space (No. 85). Now the base CG of the rectangle CDKG is to the base EI of the rectangle EIMe in the same compounded ratio; therefore the force in C is to the force in E as CG to EI.

Of Accelerating and Retarding Forces.

Scales of force, velocity, acceleration, time, &c.

98. The line hko (fig. 18) was called by Dr Barrow (who first introduced this extensive employment of motion into geometry) the SCALE *of velocities;* and the line FHL (fig. 19) was named by him the *scale of accelerations.* Hermann, in his *Phoronomia*, calls it the *scale of forces.* We shall retain this name, and we may call hko of fig. 18 the *scale* of accelerations, when the areas represent the velocities. Sir Isaac Newton added another scale of very great use, viz. a scale of times. It is constructed as follows.

99. Let ABE (fig. 19) be the line along which a body is accelerated, and let FHI be the scale of forces, that is, having its ordinates FB, HD, IE, &c. proportional to the forces acting at B, D, E, F, &c.; let fhi be another line so related to ABE, that Cg is to Ei in the inverse subduplicate ratio of the area BFGC to the area BFIE; or, to express it more generally, let the squares of the ordinates to the line fgi be inversely as the areas of the line FHI intercepted between these ordinates and the first ordinate drawn through B; then the times of the bodies moving from a state of rest in B are as the intercepted areas of the curve fgi.

For let CD and Ee be two very small portions of the space described in equal times. They will be ultimately as the velocities in C and E. The area FBCG is to the area FBEI as the square of Ei to the square of Cg (by construction); but the area FBCG is to FBEI as the square of the velocity at C to the square of the velocity at E (by the proposition); therefore the square of the velocity at C is to the square of the velocity at E as the square of Ei to the square of Cg; therefore Ei is to Cg as the velocity at C to the velocity at E, that is, as CD to Ee: but since Ei : Cg = CD : Ee, we have Ei × Ee = Cg × CD, and the elementary rectangles C$gk$D and Eime are equal, and may represent the equal moments of time in which CD and Ee were described. Thus the areas of the line fgl will represent or express the times of describing the corresponding portions of the abscissa.

We may express the nature of this scale more briefly thus. Let BE be the space described with any varied motion, and fgl a curve, such that its ordinates are inversely as the velocities in the different points of the abscissa, then the area will be as the times of describing the corresponding portions of the abscissa.

Example of the application of No 95.

100. In all the cases where our mathematical knowledge enables us to assign the values of the ordinates of the figure 19, we can obtain the law of action of the forces, or the nature of the force; and where we can assign the value of the areas from our knowledge of the proportions of the ordinates or forces, we can ascertain the velocities of the motion. We shall give an example or two, which will show the way in which we avail ourselves of the geometrical properties of figure in order to ascertain the effects of mechanical forces.

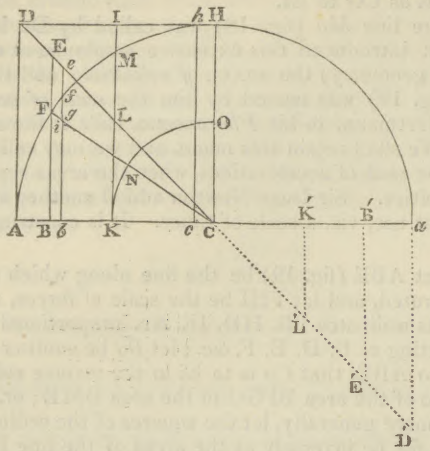
(1.) In fig. 19, let the accelerating force which impels the body along the line AB be constant, and let the body be previously at rest in B; the line which bounds the ordinates that represent the forces must be some line φHN parallel to AB. The area BDHφ is to the area BENφ as the square of the velocity at D to the square of the velocity at E. These areas, having equal bases DH and EN, are as their altitudes BD and BE; that is, the spaces described are as the squares of the acquired velocities. And we see that this characteristic mark of uniformly accelerated motion is included in this general proposition.

---

[1] Newton's *Principia*, i. 39.

Of Accelerating and Retarding Forces.

Fig. 20.



101. (2.) Let us suppose that the body is impelled from A (fig. 20), towards the point C, by a force proportional to its distance from that point. This force may be represented by the ordinates DA, EB, *eb*, &c. to the straight line DC. We may take any magnitude of these ordinates; that is, the line DC may make any angle with AC. It will simplify the investigation if we make the first force AD = AC. About C describe the circle AH*a*, cutting the ordinate EB in F; let *eb* be another ordinate, cutting the circle in *f* very near to F; draw CH perpendicular to AC, and make the arch H*h* = *f*F, and draw *hc* parallel to HC; join FC and DH, and draw F*g* perpendicular to *fb*. Let IML be another ordinate.

The area DABE is to the area DAKL as the square of the velocity at B to the square of the velocity at K. But DABE is the excess of the triangle ADC above the triangle EBC, or it is half of the excess of the square of CA or CF above the square of CB, that is, half the square of BF. In like manner, the area DAKL is equal to half the square of KM; but halves have the same ratio as the integers; therefore the square of BF is to the square of KM as the square of the velocity at B to the square of the velocity at K; therefore the velocity at B is to the velocity at K as BF is to KM. The velocities are proportional to the sines of the arches of the quadrant AFH described on AC.

Cor. 1. The final velocity with which the body arrives at C is to the velocity in any other point B as radius to the sine of the arch AF.

Cor. 2. The final velocity is to the velocity which the body would acquire by the uniform action of the initial force at A as 1 to $\sqrt{2}$; for the rectangle DACH expresses the square of the velocity acquired by the uniform action of the force DA; and this is double of the triangle DAC; therefore the squares of these velocities are as 1 and 2, and the velocities are as $\sqrt{1}$, and $\sqrt{2}$, or as 1 to $\sqrt{2}$.

102. *Cor.* 3. The time of describing AB is to the time of describing AC as the arch AF to the quadrant AFH.

For when the arch F*f* is diminished continually, it is plain that the triangle *fi*F is ultimately similar to CFB, by reason of the equal angles C*ib* (or CFB) and *fi*F, and the right angles CBF and *f*F*i*; therefore the triangles *fg*F and CBF are also similar. Moreover, B*b* is equal to F*g*, F*f* is equal to *h*H, which is ultimately equal to *c*C; therefore, since the triangles *fg*F and CFB are similar, we have F*g* : F*f* = FB : CF = FB : HC; therefore B*b* is to *c*C as FB to HC, that is, as the velocity at B to the velocity at C; therefore B*b* and *c*C are described in equal moments when indefinitely small; therefore equal portions F*f*, *h*H, of the quadrant correspond to equal moments of the accelerated motion along the radius AC; and the arches AF, FM, MH, &c. are proportional to the times of describing AB, BK, KH, &c.

Cor. 4. The time of describing AC with the unequally accelerated motion, is to the time of describing it uniformly with the final velocity as the quadrantal arch is to the radius of a circle; for if a point move in the quadrantal arch so as to be in F, *f*, M, H, &c. when the body is in B, *b*, K, C, it will be moving uniformly, because the arches are proportional to the times of describing those portions of AC; and it will be moving with the velocity with which the body arrives at C, because the arch *h*H is ultimately = C*c*. Now if two bodies move uniformly with this velocity, one in the arch AFH, and the other in the radius AC, the times will be proportional to the spaces uniformly described; but the time of describing AFH is equal to the time of the accelerated motion along AC, therefore the proposition is manifest.

103. *Cor.* 5. If the body proceed in the line C*a*, and be retarded in the same manner that it was accelerated along AC, the time of describing AC uniformly with the velocity which it acquires in C is to the time of describing AC*a* with the varied motion, as the diameter of a circle to the circumference; for because the momentary retardations at K′, B′, &c. are equal to the accelerations at K and B, &c. the time of describing AC*a* is the same with that of describing AH*a* uniformly with the greatest velocity; that is, to the time of describing AC uniformly as AH*a* to AC, or as the circumference of a circle to the diameter; therefore, &c. N. B. In this case of retarding forces it is convenient to represent them by ordinates K′L, B′E, *a*D′, lying on the other side of the axis AC*a*; and to consider the areas bounded by these ordinates as subtractive from the others. Thus the square of the velocity at K′ is expressed by the whole area DACK′L′C, the part C′K′L′ being negative in respect of the point DAC. This observation is general.

Cor. 6. The time of moving along KC, the half of AC, by the uniform action of the force at A, is to that of describing AC*a* by the varied action of the force directed to C, and proportional to the distance from it, as the diameter of a circle to the circumference; for when the body is uniformly impelled along KC by the constant force IK, the square of the velocity acquired at C is represented by half the rectangle IKCH, and therefore it is equal to the velocity which the variable force generates by impelling it along AC (by the way, an important observation). The body will describe AC uniformly with this velocity in the same time that it is uniformly accelerated along KC. Therefore by *Cor.* 5 the proposition is manifest.

Cor. 7. If two bodies describe AC and KC by the action of forces which are everywhere proportional to the distances from C, their final velocities will be proportional to the distances run over, and the times will be equal.

For the squares of the final velocities are proportiona to the triangle ADC, LKC, that is, to AC^2, KC^2, and therefore the velocities are as AC, KC. The times of describing AC and KC uniformly, with velocities proportional to AC and KC, must be equal; and these times are in the same ratio (viz. that of radius to $\frac{1}{4}$ of the circumference) to the times of describing AC and KC with the accelerated motion. Therefore, &c.

Thus, by availing ourselves of the properties of the circle, we have discovered all the properties or characters of a motion produced by a force always directed to a fixed point, and proportional to the distance from it. Some of these are remarkable, such as the last corollary; and they are all important, for there are innumerable cases where this law of action obtains in nature. It is nearly the law

Of ccele- rating and Rerding Fces.

of action of a bowstring, and of all elastic bodies, when their change of figure during their mutual action is moderate; and it has been by the help of this proposition first demonstrated in a particular case by Lord Brouncker and Mr Huygens, that we have been able to obtain precise measures of time, and consequently of actual motions, and consequently of any of the mechanical powers of nature. It is for this reason, as well as for the easy and perspicuous employment of the mathematical method of proceeding, that we have selected it.

Instead of giving any more particular cases, we may observe in general, that if the intensity of the force be proportional to any power whose index is $n-1$ of the distance, and if a be the distance from the fixed point at which the body begins to be accelerated, and x its distance from the point in any part of the motion, the velocity will be $\doteqdot\sqrt{a^n - x^n}$. This is very plain, because the increment CGHD of the area of fig. 19, which is also the increment of the square of the velocity, is $\doteqdot x^{n-1}dx$, and the area is $\doteqdot x^n$; and the whole area, corresponding to the distance a, is a^n. Therefore the portion of the area lying beyond the distance x is $a^n - x^n$. This is as the square of the velocity, and therefore the velocity is as the square root $\sqrt{a^n - x^n}$ of this quantity.

This proposition, $fds \doteqdot vdv$, or $f \doteqdot \frac{vdv}{ds}$, is the 39th of the first book of Newton's *Principia*, and is perhaps the most important in the whole doctrine of dynamics, whether employed for the investigation of forces or for the explanation of motions. It furnishes the most immediate data for both purposes, but more especially for the last. By its help Sir Isaac Newton was able to point out the numerous disturbances of the planetary motions, and to separate them from each other; thus unravelling, as it were, that most intricate motion in which all are blended together. He has given a most wonderful specimen of its application in his Lunar Theory.

We now are able to explain all the puzzling facts which were adduced by Leibnitz and his partisans in support of their measure of the forces of bodies in motion. We see why four springs, equally bent, communicate but a double velocity, and nine springs but a triple velocity; why a bullet moving twice as fast will penetrate an earthen rampart to a quadruple depth, &c. &c.

Cserva- t virium vrum.

This theorem also gives a most perspicuous explanation of the famous doctrine called *conservatio virium vivarum*. When perfectly elastic bodies act on each other, it is found that the sum of the masses multiplied by the squares of the velocities is always the same. This has been substituted, with great encomiums, by the German philosophers, in place of Descartes's principle, that the quantity of motion in the universe, estimated in one direction, remains always the same. They are obliged, however, to acknowledge, that in the actions of perfectly hard bodies, there is always a loss of *vis viva*, and therefore have denied the existence of such bodies. But there is the same loss in the mutual actions of all soft or ductile, or even imperfectly elastic, bodies; and they are miserably puzzled how to explain the fact; but both the *conservatio* and the *amissio* are necessary consequences of this theorem.

In the collision of elastic bodies, the whole change of motion is produced during the short time that the bodies are compressed, and while they regain their figure. When this is completed, the bodies are at the same distance from each other as when the mutual action began. Therefore the preceding body has been accelerated, and the following body has been retarded along equal spaces; and in every point of this space the accelerating and the retarding force has been equal. Consequently the same area of fig. 20 expresses the change made on the square of the velocity of both bodies. Therefore, if V and U are the velocities before collision, and v and u the velocities after collision, of the two bodies A and B, we must have $A \times \overline{V^2 - v^2} = B \times \overline{u^2 - U^2}$, and therefore $A \times V^2 + B \times U^2 = A \times v^2 + B \times u^2$.

Of Accelerating and Retarding Forces.

But in the other class of bodies, which do not completely regain their figure, but remain compressed, they are nearer to each other when their mutual action is ended than when it began. The foremost body has been accelerated along a shorter space than that along which the other has been retarded. The mutual forces have in every instant been equal and opposite. Therefore the area which expresses the diminution of the square of the velocity must exceed the area expressing the augmentation by a quantity that is always the same when the permanent compression is the same; that is, when the relative motion is the same. $A \times \overline{V^2 - v^2}$ must exceed $B \times \overline{u^2 - U^2}$, and $A \times V^2 + B \times U^2$ must exceed $A \times v^2 + B \times u^2$.

This same theorem is of the most extensive use in all practical questions in mechanic arts; and without it mechanics can go no farther than the mere statement of equilibrium.

History of No. 95 is curious.

Hermann, professor of mathematics at Pavia, one of the ornaments of the mathematical class of philosophers, has given a pretty demonstration of this valuable proposition, in the *Acta Eruditorum Lipsiæ* for 1709; and says, that having searched the writings of the mathematicians with great care, he found himself warranted to say, that Newton was the undoubted author, and boasts of his own as the first synthetical demonstration. The purpose of this assertion was not very apparent at the time; but long after, in 1746, when Hermann's papers, preserved in the town-house of Pavia, were examined, in order to determine a dispute between Maupertuis and Koenig about the claim to the discovery of *the principle of least action*, letters of Leibnitz's were found, requesting Hermann to search for any traces of this proposition in the writings of the mathematicians of Europe. Leibnitz was by this time the envious detractor from Newton's reputation, and could not but perceive that all his contorted arguments for his doctrine received a clear explanation by means of this proposition, in perfect conformity to the usual measure of moving forces. Newton had discovered this theorem long before the publication of the *Principia*, and even before the discovery of the chief proposition of that book in 1666; for in his Optical Lectures, the materials of which were in his possession in 1664, he makes frequent use of a proposition founded on this. (See No. 42.) We may here remark, that Hermann's demonstration is in every step the same with Dr Barrow's demonstration of it as a theorem merely geometrical, without speaking of moving forces (see *Lect. Geometr.* xi. p. 85, edit. 16), but giving it as an instance of the transformation of curves, which he calls *scales* of velocity, of time, of acceleration, &c. It is very true that Barrow in these mathematical lectures approached very near to both of Newton's discoveries, the fluxionary geometry, and the principles of dynamics; and the junto on the Continent, who were his continual detractors, charge him with impudent plagiarism from Dr Barrow, and even say that he has added nothing to the discoveries of his teacher. But surely Dr Barrow was the best judge of this matter; and, so far from resenting the use which Newton has made of what he had taught him, he was charmed with the genius of the *juvenis spectatissimus* his scholar, and of his own accord gave him his professorial chair, and ever after lived in the utmost harmony and friendship with him. Nay, it would even appear from some expressions in those very lectures, that Dr Barrow owed to young Newton the first thought of making such extensive use of motion in geometry. We recommend this work of Barrow's to the serious perusal of our readers, who wish to acquire clear notions of the science of motion, and an elegant taste in their mechanical disquisitions. After all the cultivation of this science by the commentators and followers of Newton, after the *Phoronomia* of Hermann, the *Mechanica* of Euler, the *Dynamique* of D'Alembert, and the *Mechanique Analytique* of De la Grange, which are undoubtedly works of transcendent merit and utility, the *Principia* of Newton will still remain the most pleasing, perspicuous, and elegant specimen of the application of mathematics to the science of *universal mechanics*, or what we call DYNAMICS.

The two fundamental theorems $fdt = dv$, and $fds = vdv$, enable us to solve every question of motion accelerated or retarded by the action of the mechanical powers of nature. But the employment of them may be greatly expedited and simplified by noticing two or three general cases which occur very frequently.

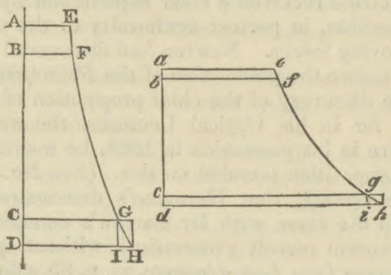
Similar instants and points, what.

104. *These may be called similar instants of time, and similar points of space which divide given portions of time, and of space in the same ratio.* Thus the middle is a similar instant of an hour or of a day, and is the similarly situated point of a foot or of a yard. The beginning of the 21st minute, and of the 9th hour, are similar instants of an hour and of a day. The beginning of the fifth inch, and of the second foot, are similar points of a foot and of a yard.

Similar actions, what.

105. *Forces may be said to act similarly when their intensities in similar instants of time, or in similar points of space, are in a constant ratio.* Thus in fig. 20, when one body is impelled towards C from A, and another from K, each with a force proportional to the distance of every point of its motion from C, these forces may be said to act similarly along the spaces AC and KC, or during the times represented by the quadrantal arches AFH, KNO. The following propositions on similar actions will be found very useful on many occasions; but we must premise a geometrical lemma.

Fig. 21.

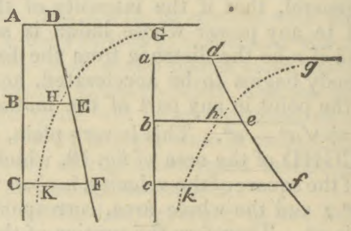


106. If there be two lines EFGH (fig. 21), *efgh*, so related to their abscisses AD, *ad*, that the ordinates BF, *bf*, drawn from similar points B and *b* of the abscisses, are in the constant ratio of AE to *ae*; then the area ADHE is to the area *adhe* as the rectangle of AD × AE to the rectangle *ad* × *ae*.

For, let each abscissa be divided into the same number of equal and very small parts, of which let CD and *cd* be one in each. Inscribe the rectangles CGID, *cgid*. Then because the number of parts in each axis is the same, the lengths of the portions CD and *cd* will be proportional to the whole abscisses AD and *ad*. And because C and *c* are similar points, CG is to *cg* as AE is to *ae*. Therefore $CD \times CG : cd \times cg = AD \times AE : ad \times ae$. This is true of each pair of corresponding rectangles, and therefore it is true of their sums. But when the number of these rectangles is increased, and their breadth diminished without end, it is evident that the ultimate ratio of the sum of all the rectangles, such as CDHG, to the sum of all the rectangles *cdhg*, is the same with that of the area ADHE to the area *adhe*, and the proposition is manifest.

107. *If two particles of matter are similarly impelled during given times, the changes of velocity are as the times and as the forces jointly.*

Fig. 22.



Let the times be represented by the straight lines ABC (fig. 22), and *abc*, and the forces by the ordinates AD, BE, CF, and *ad*, *be*, *cf*. Then if B and *b* are similar instants (suppose the middles) of the whole times, we have $BE : be = AD : ad$. Therefore, by the lemma, the area ACFD is to *acfd* as AC × AD to *ac* × *ad*. But these areas are proportional to the velocities (No. 72), and the proposition is demonstrated. For the same reason, the change of velocity during the time AB is to the change during *ab* as AB × AD to *ab* × *ad*.

Cor. 1. If the times and forces are reciprocally proportional, the changes of velocity are equal; and if the forces are inversely as the times, the changes of velocity are equal.

108. *If two particles be similarly urged along given spaces, the changes made on the squares of the velocities are as the forces and spaces jointly.*

For if AC (fig. 22) and *ac* are the spaces along which the particles are impelled, and the forces are as the ordinates AD and *ad*, the areas ACFD and *acfd* are as the changes on the squares of the velocities. But these areas are as AC × AD, and *ac* × *ad*. Therefore, &c.

Cor. 2. If the spaces are inversely as the forces, the changes of the squares of the velocities are equal; and if these are equal, the spaces are inversely as the forces.

Cor. 3. If the spaces along which the particles have been impelled from a previous state of rest, are directly as the forces, the velocities are also as the forces. For, because the changes of the squares of the velocities are as the spaces and forces jointly, they are in this case as the squares of the forces or of the spaces; but the changes of the squares of the velocities are in this case the whole squares of the velocities; therefore the squares of the velocities are as the squares of the forces, and the velocities are as the forces. N. B. This includes the motions represented in fig. 20.

109. *If two particles be similarly impelled along given spaces, from a state of rest, the squares of the times are proportional to the spaces directly, and to the forces inversely.*

Let ABC (fig. 22), *abc*, be the spaces described, and AD, *ad*, the accelerating forces at A and *a*. Let V, B express the velocity at B, and *v*, *b* the velocity at *b*.

Let GHK and *ghk* be curves whose ordinates are inversely as the velocities at the corresponding points of the abscissa. These curves are therefore exponents of the times (No. 99). Then, because the forces act similarly, we have, by the last theorem, $AC \times AD : ac \times ad = V^2, B : v^2, b, = hb^2 : HB^2$. Therefore $HB : hb = \sqrt{ac \times ad} : \sqrt{AC \times AD}$, and therefore in a con-

Of accelerating and Retarding Forces.

stant ratio. Call this the ratio of m to n. But since the ordinates of the lines GHK, *ghk*, are inversely as the velocities, the areas are as the times (No. 99); and since these ordinates are in the constant ratio of m to n, the areas are in the ratio of $\mathrm{AC} \times m$ to $ac \times n$. Therefore (calling the times of the motions T and t), we have

$$\mathrm{T} : t = m \times \mathrm{AC} : n \times ac; \text{ and therefore}$$
$$\mathrm{T}^2 : t^2 = m^2 \times \mathrm{AC}^2 : n^2 \times ac^2. \text{ But}$$
$$m^2 : n^2 = ac \times ad : \mathrm{AC} \times \mathrm{AD}. \text{ Therefore}$$
$$\mathrm{T}^2 : t^2 = ac \times ad \times \mathrm{AC}^2 : \mathrm{AC} \times \mathrm{AD} \times ac^2,$$
$$\text{or } \mathrm{T}^2 : t^2 = ad \times \mathrm{AC} : \mathrm{AD} \times ac.$$
$$\text{Or } \mathrm{T}^2 : t^2 = \frac{\mathrm{AC}}{\mathrm{AD}} : \frac{ac}{ad}.$$

The attentive reader will observe that these three propositions give a great extension to the theorems which were formerly deduced from the nature of uniformly accelerated motion, or of uniform action of the forces, and were afterwards demonstrated to obtain in the momentary action of forces any how variable.

The first of the three propositions, $\mathrm{V} : v = \mathrm{F} \times \mathrm{T} : f \times t$, is the extension of the theorem $fdt = dv$. The second, $\mathrm{V}^2 : v^2 = \mathrm{F} \times \mathrm{S} : f \times s$, is the extension of the theorem $fds = vdv$. And the third, $\mathrm{T}^2 : t^2 = \frac{\mathrm{S}}{\mathrm{F}} : \frac{s}{f}$, is the extension of $f = \frac{ds}{d(t^2)}$, or of $fd\,(t^2) = ds$. These theorems hold true of all *similar* actions; and, only for this reason, are true of uniformly accelerated motions, or uniform actions.

Aggregate of any equal accelerating forces.

There remains one thing more to be said concerning the action of accelerating forces. Their magnitude is ascertained by their effect. Therefore that is to be considered as a double force which produces a double quantity of motion. Therefore when a body A contains twice the number of equal atoms of matter, and acquires the same velocity from the action of the force F, that another body *a*, containing half the number of atoms, acquires from the action of a force *f*, we conceive F to be double of *f*. That this is a legitimate inference appears clearly from this, that we conceive the sensible weight of a body, or that pressure which it exerts on its supports, as the aggregate of the equal pressure of every atom accumulated perhaps on one point; as when the body hangs by a thread, and, by its intervention, pulls at some machine. Without inquiring in what manner or by what intervention this accumulation of pressure is brought about, we see clearly that it results from the equal accelerating force of gravity acting immediately on each atom. When this weight is thus employed to move another body by the intervention of the thread, which is attached to one point perhaps of that body, it puts the whole into motion, generating a certain velocity v in every atom, by acting uniformly during the time t. We conceive each atom to have sustained the action of an equal accelerating force whose measure is $\frac{v}{t}$. Without considering how this force is exerted on each atom, or by what it is immediately exerted, or how it is diffused through the body from the point to which the weight of the other body is applied by means of the thread; we still consider it as the aggregate of the action of gravity on each atom of that other body. Moreover, attending only to the motion produced by it, and perhaps not knowing the weight of the impelling body, we measure it, as a moving force, by considering it as the aggregate of the forces propagated to each atom of the impelled body, and measured by $\frac{v}{t}$. If we know that the impelled body contains the number m of atoms, the aggregate of forces is $m\frac{v}{t}$, or $\frac{mv}{t}$.

Of Deflecting Forces.

But since we measure forces by the quantity of motion which they produce, we must conceive, that when the same force is applied to a body which consists of n particles, and produces the velocity u, by acting uniformly during the same time t, the force $n\frac{u}{t}$ is equal to the force $m\frac{v}{t}$.

Moving force, motive force, vis motrix, as distinguished from accelerating force.

110. Sir Isaac Newton found it absolutely necessary, in the disquisitions of natural philosophy, to keep this circumstance of acceleration clear of all notions of quantity of matter, or other considerations, and to contemplate the affections of motion only. He therefore considered $\frac{v}{t}$ as the true original measure of accelerating force, and $m\frac{v}{t}$ as an aggregate. He therefore calls the aggregate a *vis motrix*, a *moving force*, measured by the *quantity of motion* that it generates. And he confines the term *accelerating force* to the quantity $\frac{v}{t}$ measured by the *acceleration* or *velocity* only. It would be convenient, therefore, also to confine the symbol f to $m\frac{v}{t}$, and to retain the symbol a for expressing the accelerating force $\frac{v}{t}$.

This appellation of *motive force* is perfectly just and simple; for we may conceive it as the same with the accelerating force which produces the velocity m times v in one particle, by acting on it uniformly during the time t. This motion of one particle having the velocity mv, is the same with that of m particles having each the velocity v.

If therefore a motive force f act on a body consisting of m particles, the accelerating force a is $= \frac{f}{m}\frac{v}{t}$.

Therefore the three last propositions concerning the similar, the uniform, or the momentary actions of *moving* forces, when expressed in the most general terms, are,

$$v' \doteqdot \frac{f}{mt'},$$
$$v^{2\prime} \doteqdot \frac{fs'}{m}, \text{ or } vdv = \frac{fds}{m},$$
$$t^2 \doteqdot \frac{ms'}{f}.$$

OF DEFLECTING FORCES.

Deflecting forces.

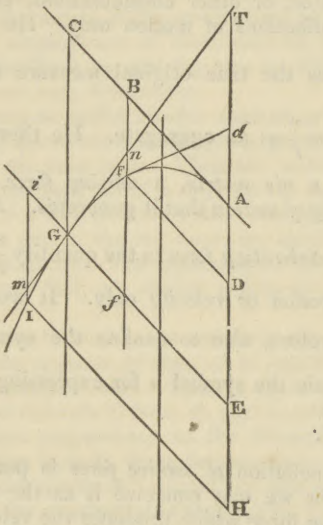
111. When we observe the direction of a body to change, we unavoidably infer the agency of a force which acts in a direction that does not coincide with that of the body's motion; and we may distinguish this circumstance by calling it a *deflecting force*. We have already shown how to estimate and measure this deflecting force, by considering it as competent to the production of that motion which, when compounded with the former motion, will produce the new motion (No. 44). Now, as all changes of motion are really compositions of motions or forces, it

is evident that we shall explain the action of deflecting forces when we show this composition.

Alteration of deflections are continual, and produce curvilineal motions.

We may almost venture to say *a priori*, that all deflections must be continual, or exhibit curvilineal motions: for as no finite velocity, or change of velocity, can be produced in an instant by the action of an accelerating force, no polygonal or angular deflection can be produced; because this is the composition of a finite velocity produced in an instant. Deflective motions are all produced by the composition of the former motion, having a finite velocity, with a transverse motion continually accelerated from a state of rest. Of this we can form a very distinct notion, by taking the simplest case of such accelerated motion, namely, a uniformly accelerated motion.

Fig. 23.



Example. Determination of the path,

112. Let a body be moving in the direction AC (fig. 23) with any constant velocity, and when it comes to A, let it be exposed to the action of an accelerating force, acting uniformly in any other direction AE. This alone would cause the body to describe AE with a uniformly accelerated motion, so that the spaces AD, AE, would be as the squares of the times in which they are described. Therefore, if AB be the space which it would have described uniformly in the time that it describes AD by the action of the accelerating force, and AC the space which it would have described uniformly while it describes AE by the action of the accelerating force, nothing more is wanted for ascertaining the real motion of the body but to compound the uniform motion in the direction AC with the uniformly accelerated motion in the direction AE. AD is to AE as the square of the time of describing AD to the square of the time of describing AE; that is, as the square of the time of describing AB to the square of the time of describing AC; that is, as AB^2 to AC^2 (by reason of the uniform motion in AC). This composition is performed by taking the simultaneous points B, D, and the simultaneous points C, E, and completing the parallelograms ABFD, ACGE. The body will be found in the points F and G in the instants in which it would have been found at B and C by the uniform motion, or in D and E by the accelerated motion. In the same manner may be found as many points of the real path as we please. It is plain that these points will be in a line AFG, so related to AE that $AD : AE = DF^2 : EG^2$; or so related to the original motion AC, that $AB^2 : AC^2 = BF : CG$, &c. This line is therefore a parabola, of which AE is a diameter, DF and EG are ordinates, and which touches AC in A.

Having thus ascertained the path of the body, we can also ascertain the motion in that path; that is, the velocity in any point of it. We know that the velocity in the point G is to the velocity of the uniform motion in the direction AC as the tangent TG is to the ordinate EG; because this is the ultimate ratio of the momentary increment of the arch AFG to the momentary increment of the ordinate EG. Thus is the velocity in every point of the curve determined. We have taken it for granted that the line of projection touches the path, and that the direction in every point is that of the tangent. To suppose that the curve, in any portion of it, coincides with the tangent, is to suppose that the body is not deflected, that is, is not acted on by a transverse accelerating force; and to suppose that the tangent makes a finite angle with any part of the path, is to suppose that the deflection is not continual, but by starts, both of which are contrary to the conditions of the case. No straight line can be drawn between the direction of the body and the succeeding portion of the path, otherwise we must again suppose that the deflection is subsultory, and the motion angular.

113. But while the investigation is so easy when the direction and intensity of the deflecting force in every point of the curve are known, the investigation of the deflecting force from the observed motion is by no means easy. The observed curvilineal motion always arises from a composition of a uniform motion in the tangent with some transverse motion; but the same curvilineal motion may be produced by compounding the uniform motion in the tangent with an infinity of transverse motions, and the law of action will be different in these transverse motions according as their directions differ. We must learn not only the intensity of the deflecting force, and the law of its variation, but also its direction in every point of the curve. It is not easy to find general rules for discovering the direction of the transverse force; most commonly this is indicated by extrinsic circumstances. The deflecting force is frequently observed to reside in or to accompany some other body. It may be presumed, therefore, that it acts in the direction of the line drawn to or from that body; yet even this is uncertain. The most general rule for this investigation is to observe the place of the body at several intervals of time before and after its passing through the point of the curve, where we are interested to find its precise direction. We then draw lines joining those places of the tangent where the body would have been by the uniform motion only. We shall perhaps observe these lines of junction keep in parallel positions: we may be assured that the direction of the transverse force is the same with that of any of these lines. This is the case in the example just now given of a parabolic motion; but when these lines change position they will change it gradually, and their position in the point of contact is that to which their positions on both sides of it gradually approximate.

But all this is destitute of the precision requisite in philosophical discussion. We are indebted to Sir Isaac Newton for a theorem which ascertains the direction of the transverse force with all exactness, in the cases in which we most of all wish to attain mathematical accuracy, and which not only opened the access to those discoveries which have immortalized his name, but also pointed out to him the path he was to follow, and even marked his first steps. It therefore merits a very particular treatment.

g force.

114. If a body describes a curve line ABCDEF (fig. 24) lying in one plane, and if there be a point S so situated in this plane that the line joining it with the body describes areas ASB, ASC, ASD, &c. proportional to the times in which the body describes the arches AB, AC, AD, &c. the force which deflects the body from rectilineal motion is continually directed to the fixed point S.

Let us first suppose that the body describes the polygon ABCDEF, &c. formed of the chords AB, BC, CD, DE, EF, &c. of this curve, and, for greater simplicity of argument, let us consider areas described in equal successive times; that is, let us suppose that the triangles ASB, BSC, CSD, &c. are equal, and described in equal times. Make B*c* = AB, and draw *c*S.

eas ∓ to
e times
licate
ntral
rces.

Had the motion AB suffered no change in the point B, the body would have described B*c* in the equal moment succeeding the first; but it describes BC. The body has therefore been deflected by an external force, and BC is the diagonal of a parallelogram (No. 45, 46), of which B*c* is one side, and *c*C is another. The deflecting force will be discovered, both in respect of direction and intensity, by completing the parallelogram B*c*C*b*. B*b* is the space which the deflecting force would have caused the body to describe in the time that it describes B*c* or BC. Because B*c* is equal to BA, the triangles BS*c*, BSA are equal. But, by the nature of the motion, BSA is equal to BSC; therefore the triangles BSC and BS*c* are equal. They are also on the same base BS; therefore they lie between the same parallels, and C*c* is parallel to SB. But *c*C is parallel to B*b;* therefore B*b* coincides with BS, and the deflecting force at B is directed toward S. By the same argument, the deflecting force at the angles D, E, F, &c. is directed to S.

Now, let the sides of the polygon be diminished, and their number increased without end. The demonstration remains the same, and continues, when the polygon finally coalesces with the curve, and the deflection is continual.

When areas are described proportional to the times, equal areas are described in equal times; and therefore the deflection is always directed to S. Q. E. D.

ces.

The point S may, with equal propriety of language, be called the *centre of deflection*, or *the centre of forces;* and forces which are thus continually directed to one fixed point may be distinguished from other deflecting forces by the name *central forces.*

Of Deflecting Forces.

Radius vector.

The line joining the centre of forces with the body, and which may be conceived as a stiff line carrying the body round, is usually named the *radius vector.*

Central forces produce areas proportional to the times.

115. The converse of this proposition, viz. that if the deflecting forces be always directed to S, the motion is performed in one plane, in which S is situated, and areas are described proportional to the times, is easily demonstrated by reversing the steps of this demonstration. The motion will be in the plane of the lines SB and B*c*, because the diagonal BC of the parallelogram of forces is in the plane of the sides. Areas are described proportional to the times; for C*c* being parallel to SB, the triangles SCB and S*c*B are equal; and therefore SCB and SAB are equal, &c. &c.

Velocity is inversely as the perpendicular from the centre.

116. *Cor.* 1. When a body describes areas round S proportional to the times, or when it is continually deflected toward S, or acted on by a transverse force directed to S, the velocities in the different points A and E of the curve are inversely proportional to the perpendiculars S*r* and S*t*, drawn from the centre of forces to the tangents in those points; that is, to the perpendiculars from the centre on the momentary directions of the motion: for since the triangles ASB, ESF are equal, their bases AB, EF are inversely as their altitudes S*r*, S*t;* but these bases being described in equal times, are as the velocities, and they ultimately coincide with the tangents at A and E.

117. *Cor.* 2. If Bα and Fε be drawn perpendicular to SA and SE, we have SA × Bα = SE × Fε, and SA : SE = Fε : Bα. For SA × Bα is double of the triangle BSA, and SE × Fε is double of the equal triangle SFE.

Angular velocity is inversely as the square of the distance from the centre of forces.

118. *Cor.* 3. The angular velocity round S, that is, the magnitude of the angle described in equal times by the radius vector, is inversely proportional to the square of the distance from S. For when the arches AB, EF are diminished continually, the perpendiculars Bα and Fε will ultimately coincide with arches described round S with the radii SB and SF. Now the magnitude of an angle is proportional to the length of the arch which measures it directly, and to the radius of the arch inversely. In any circle, an arch of two inches long measures twice as many degrees as an arch one inch long; and an arch one inch long contains twice as many degrees of a circle whose radius is twice as short. Therefore, ultimately, the angle ASB is to the angle ESF as Bα to Fε, and as SF to SB jointly; that is, as Bα × SF to Fε × SB. But Bα : Fε = SE : SA (Cor. 2); therefore ASB : ESF = SE × SF : SB × SA, = ultimately $SE^2 : SB^2$.

This corollary gives us an ostensible mark, in many very important cases, of the action of a deflecting force being always directed to a fixed point. We are often able to measure the angular motion when we cannot measure the real velocities.

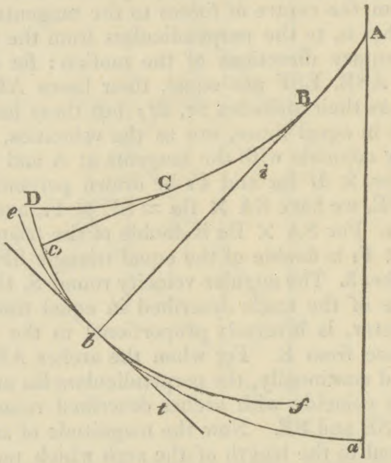
Intimate connection of dynamics and the higher geometry.

Having thus discovered the chief circumstances which enable us to ascertain the direction of the deflecting force, we proceed to investigate the quantity of this deflective determination in the different points of a curvilineal motion. This is a more difficult task. The momentary effect of the deflecting force is a small deviation from the tangent; and this deviation is made with an accelerated motion. The law of this acceleration regulates the curvature of the path, and is to be determined by it. We may be allowed to observe by the way, that it appears clearly, from the form in which Newton has presented all his dynamical theorems, that we are indebted to these problems for the immense improvement which he has made in geometry by his invention of fluxions. The purposes he had in view suggested to his penetrating mind the means for attaining them; and the connection between dynamics and geometry is so intimate, that the same theorems are in a manner common to both. This is particularly the case in all that relates to curvature. Or shall we say that the geometry of Dr Barrow suggested the dynamical theorems to Newton? We have seen how the curvature of a parabola is produced by a force acting uniformly. The *momentary* action of all finite forces may be considered as uniform, and therefore the curvature will be that of some portion of some parabola; but it will be difficult to determine the precise degree without some farther help. We are best acquainted with the properties of the circle, and will have the clearest notions of the curvature of other curves by comparing them with circles.

Measure of curvature.

The curvature of a circular arch of given length is so much greater as its radius is shorter, for it will contain so many more degrees in the same length; and therefore the change of direction of its extremities is so much greater. Curvatures may always be measured by the length of the arch directly, and the radius inversely.

Fig. 25.



Evolution and involution of curves.

119. Suppose a thread made fast at one end of a material curve ABCD (fig. 25), and applied to it in its whole length. Taking hold of its extremity D, unfold it gradually from the curve DCBA; the extremity D will describe another curved D*cba*. This geometrical operation is called the *evolution* of curves, and D*cba* is called the *evolute* of DCBA, which is called the *involute* of D*cba*. Perhaps this denomination has been given from the genesis of the area or surface contained by the two lines, which is folded up and unfolded somewhat like a fan. When the describing point is in *b*, the thread *b*B is undoubtedly the momentary radius of a circle *ebf*, whose centre is B, the point of the involute which it is just going to quit. The momentary motion of *b* is the same, whether it is describing an arch of the evolute passing through *b*, or an arch of a circle round the centre B. The same line *bt*, perpendicular to the thread *b*B, touches the circle *ebf* and the curve D*ba* in the point *b*. This circle *ebf* must lie within the curve D*ba* on the side of *b*B toward *a*, because on this side the momentary radius is continually increasing. For similar reasons, the circle *ebf* lies without the curve on the other side of *b*B. Therefore the circle *ebf* both touches and cuts the curve D*ba* in the point *b*. Moreover, because every portion of the curve between *b* and D is described with radii that are shorter than *b*B, it must be more incurvated than any portion of the circle *ebf*. For similar reasons, every portion of the curve between *b* and *a* must be less incurvated than this circle; therefore the circle has that precise degree of curvature that belongs to the curve in the point *b*; it is therefore called the *equicurve circle*, or the *circle of curvature*, and B is called the centre, and B*b* the *radius of curvature*. It is easy to perceive that no circle can be described which shall touch the curve in *b*, and come between it and the circle *ebf*; for its centre must be in some point *i* of the radius *b*B. If *ib* be less than B*b*, it must fall within the curve on both sides of *b*, and if *ib* is greater than B*b*, the circle must fall without the curve on both sides of B*b*. The circle *ebf* lies closer to the curve, has closer contact with it than any other, and has therefore got the whimsical name of *osculating circle;* and this sort of contact was called *osculation*.

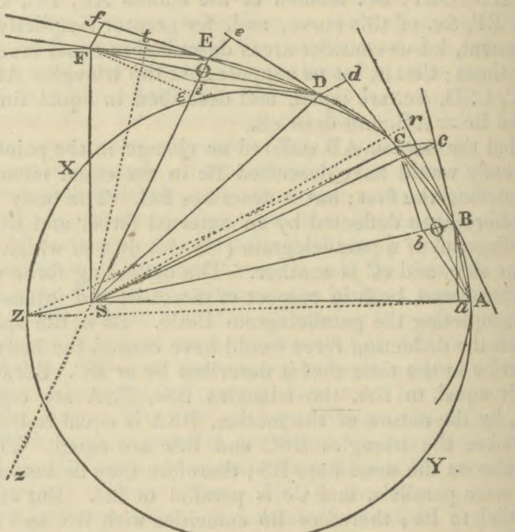
Circle of curvature. Equicurve circle.

This view of the genesis of curve lines is of particular use in dynamical discussions. It exhibits to the eye the perfect sameness of the momentary motion, and therefore of the momentary deflection, in the curve and in the equicurve circle, and leaves the mind without a doubt but that the forces which produce the one will produce the other. A great variety of curves may be described in this way. If perpendiculars be drawn to the curve D*ba* in every point, they will intersect each other, each its immediate neighbour, in the circumference of the curve DBA; and geometry teaches us how to find the curve DBA which shall produce the curve D*ba* by evolution. (See FLUXIONS.)

It is a matter worthy of remark, that the path of a body that is deflected from rectilineal motion by a *finite* force, varying according to any law whatever, may always be described by evolution. This includes almost every case of the action of deflecting forces; none being excepted but when, by the opposite action of different forces, the body is in equilibrio in one single point of its path.

Our task is now brought within a very narrow compass, namely, to measure the deflection in the arch of a circle.

Fig. 26.



Had the motion represented in fig. 26 been polygonal, it is plain that the deflecting force in the point B is to that in the point E as the diagonal B*b* of the parallelogram ABC*b* to the diagonal E*i* of the parallelogram DEF*i;* therefore let ABCZY be a circle passing through the points A, B, and C, and let the radius vector BS cut the circumference in Z; draw AZ, CZ, and the diagonal AC, which necessarily bisects and is bisected by the diagonal B*b*. The triangles *b*BC and CBZ are similar; for the angle C*b*B is equal to the alternate angle AB*b* or ABZ, which is equal to the angle ACZ, standing on the same chord AZ. And the angle CB*b*, or CBZ, is equal to CAZ, standing on the same chord CZ; therefore the remaining angle *b*CB is equal to the remaining angle

Ofeflect- in orces. AZC; therefore ZA is to AC as BC to B*b*, and B*b* $= \frac{AC \times BC}{AZ}$. In like manner E*i* $= \frac{DF \times EF}{Dz}$.

M sure of de cting for s. Now let the points A and C continually approach, and ultimately coalesce with B; it is evident that the circle ABCZY is ultimately the equicurve or coinciding circle at the point B, and that AS ultimately coalesces with and is equal to BS, and that AC × BC is ultimately 2BC²; therefore ultimately $Bb : Ei = \frac{2BC^2}{BZ} : \frac{2EF^2}{Ez}$, or $= \frac{BC^2}{\frac{1}{2}BZ} : \frac{EF^2}{\frac{1}{2}Ez}$.

Now BC and EF being described in equal times, are as the velocities: B*b* and E*i* are the measures of the velocities which the deflective forces at B and E would generate in the time that the body describes BC or EF, and are therefore the measures of those forces. *They are as the squares of the velocities directly, and inversely as those chords of the equicurve circles which have the directions of the deflection.*

Observe that B*b* or E*i* is the third proportional to half of the chord and the arch described; for $Bb : BC = BC : \frac{BZ}{2}$.

It is evident, that as the arches AB, BC, continually diminish, AC is ultimately parallel to the tangent B*r*, and BO is equal to the actual deflection from the tangent. The triangles BOC and AOZ are similar, and $BO = \frac{OC^2}{OZ}$, or ultimately $= \frac{BC^2}{BZ}$. We may measure the forces by the actual deflections, because they are the halves of the measures of the generated velocities; and we may say that

asure of ection. 120. *The actual momentary deflection from the tangent is a third proportional to the deflective chord of the equicurve circle and the arch described during the moment.*

ution. Either of these measures may be taken, but we must take care not to confound them. The first is the most proper, because the change produced on the body (which is the *immediate* effect and measure of the force) is the determination left inherent in it to move with a certain velocity. This is the measure also which we obtain by means of the differential or fluxionary calculus; but the other measure must be obtained when our immediate object is to mark the actual path of the body. The steps of this demonstration, which is Newton's, naturally terminate in the equicurve circle, and give at once the immediate measure of the deflecting force. At the same time the reader must perceive that this measure does not depend on the force being always directed to one centre; it is enough that the two sides of the polygon, in immediate succession, are described in equal times. This is necessary in order that ABC*b* may be a parallelogram, and that the diagonals AC and B*b* may mutually bisect each other.

Thus have we obtained a measure of deflecting force, and, in the most important cases, a method of discovering its direction. It only remains to point out the relation between the intensity of the force, the curvature of the path, and the velocity of the motion. These three circumstances have a necessary connection; for we see that the intensity is expressed by certain values of the other two in the formula $f \doteq \frac{\text{Arch}^2}{\frac{1}{2}\,\text{Chord}}$, or $f = \frac{2\,BC^2}{BZ}$. The deflective velocity B*b* is acquired in the time that the body describes BC; therefore the deflective velocity is to the velocity in the curve as B*b* to BC. The velocity B*b* is acquired by an accelerated motion along BO; for while, by progressive motion, the body describes BC, it deflects from the tangent through a space equal to the half of B*b*, because the momentary action of the deflecting force may be considered as uniform. The progressive velocity BC may be generated by the same force uniformly acting through a space greater than BC; call this space *x*. The spaces along which a body must be uniformly impelled in order to acquire different velocities are as the squares of those velocities; therefore $Bb^2 : BC^2 = Bo : x$; but $Bb : BC = BC : \frac{1}{2}BZ$; therefore $Bb^2 : BC^2 = Bb : \frac{1}{2}BZ$, and $Bb : \frac{1}{2}BZ = Bo : x$, and $Bb : Bo = \frac{1}{2}BZ : x$; but B*o* is $\frac{1}{2}$ of B*b*, therefore *x* is $\frac{1}{4}$ of BZ; that is,

Of Deflecting Forces.

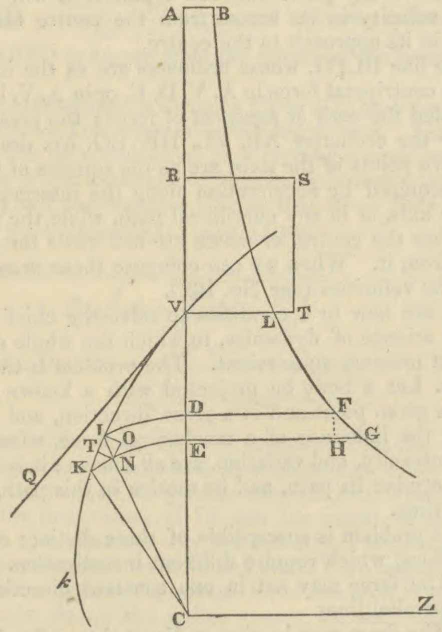
121. *The velocity in any point of a curvilineal path is that which the deflecting forces in that point would generate in the body by impelling it uniformly along one fourth part of the deflective chord of the equicurve circle.* If the velocity increase, the chord of the equicurve circle must increase; that is, the path becomes less incurvated. If the force be increased, the curvature will also increase, for the chord of curvature will be less.

There is another general observation to be made on the velocity of a curvilineal motion, which greatly assists us in our investigation.

Comparison of orbital motion with direct approach to the centre.

122. *If a body describes a curve by the action of a force always directed to a fixed point, and varying according to any proportion whatever of the distances from that point, and if another body, acted on by the same centripetal force, move toward the centre in a straight line, and if in any one case of equal distances from the centre of force the two bodies have equal velocities, they will have equal velocities in every other case of equal distances from the centre.*

Fig. 27.



Let one body be impelled from A (fig. 27) toward C along the straight line AVDEC, and let another be deflected along the curve line VIK*k*. About the centre C describe concentric arches ID, KE, very near to each other, and cutting the curve in I and K, and the line AC in D and E; draw IC, cutting KE in N, and draw NT perpendicular to the arch IK of the curve, and complete the parallelogram ITNO. Let the bodies be supposed to have equal velocities at I and at D.

Then, because the centripetal forces are supposed to be the same for both bodies when they are at equal distances, the accelerating forces at D and I may be represented by the equal lines DE and IN; but the force IN is not wholly employed in accelerating the body along the arch IK, but, acting transversely, it is partly employed in incurvating the path. It is equivalent to the two forces IO and IT, of which only IT accelerates the body. Now IKN is a right-angled triangle, as is also the triangle INT; and they are similar; therefore IN : IT = IK : IN, or DE : IT = IK : DE; that is, the force which accelerates the body along DE is to the force which accelerates the body along IK as the space IK is to the space DE; therefore (No. 86) the increment of the square of the velocity acquired along DE is equal to the increment of the square of the velocity acquired along IK. But the velocities at D and I were equal, and consequently their squares were equal; and these having received equal increments, therefore the squares of the velocities at E and K are equal, and the velocities themselves are equal. And since this is the case in all the corresponding points of the line AC and the curve VIK, the velocities at all equal distances from C will be equal.

It is evident that the conclusion will be the same, if the bodies, instead of being accelerated by approaching the centre in the straight line AC, and in the curve VIK, are moving in the opposite directions from E to A, or from I to V, and are therefore retarded by the centripetal force.

Retarded curvilineal motion always accompanied by recess from the centre.

123. *Cor.* Hence it follows, that if a body be projected from any point, such as V, of the curve, in a line tending straight from the centre, with the velocity which it had in that point of the curve, it would go to a distance VA, such, that if it were impelled along AV by the centripetal force, it would acquire its former velocity in the point V; also in any point between V and A it will have the same velocity in its recess from the centre that it has there in its approach to the centre.

The line BLFG, whose ordinates are as the intensities of the centripetal force in A, V, D, E, or in A, V, I, K, may be called the *scale* or *exponent* of force; the areas bounded by the ordinates AB, VL, DF, EG, &c. drawn from any two points of the axis, are as the squares of the velocity acquired by acceleration along the intercepted part of the axis, or in any curvilineal path, while the body approaches the centre, or which are lost while the body retires from it. When we can compute these areas we obtain the velocities (see No. 102).

We are now in a condition to solve the chief problem in the science of dynamics, to which the whole of it is in a great measure subservient. The problem is this:

Inverse problem of centripetal forces.

124. Let a body be projected with a known velocity from a given point and in a given direction, and let it be under the influence of a mechanical force, whose direction, intensity, and variation, are all known; it is required to determine its path, and its motion in this path, for any given time.

This problem is susceptible of three distinct classes of conditions, which require different investigation.

1. The force may act in one constant direction; that is, in parallel lines.

2. The force may be always directed to a fixed point.

3. It may be directed to a point which is continually changing its place.

1. When the force acts in parallel lines, the problem is solved by compounding the rectilineal accelerated motion which the force would produce in its own direction with the uniform motion which the projection alone would have produced. The motion must be curvilineal when the accelerating force is transverse, in any degree whatever, to the projectile motion; and the curvilineal path must be concave on that side to which the deflecting force tends, for the force is supposed to act incessantly. The place of the body will be had for any time, by finding where the body would have been at the end of that time by each force acting alone, and by completing the parallelogram. Thus, suppose a body projected along AB (fig. 23), while it is continually acted on by a force whose direction is AD. Let D and B be the places where the body would be at the end of a given time. Then the body will, at the end of that time, be in F, the opposite angle of the parallelogram ABFD. But it has not described the diagonal AF, because its motion has been curvilineal, as we shall find by determining its place at other instants of this time.

The velocity in any point F is found by first determining the velocity at D, and making D*d* to DF as the velocity at D to the velocity at B (that is, the velocity of projection, because the motion along AB is uniform). Then draw *d*F. Then AB is to *d*F as the constant velocity of projection to the velocity at F. We have seen already (No. 112–119) that *d*F is a tangent to the curve in F. Hence we may determine the velocity at F in another way. Having determined the form of the path in the way already described, by finding its different points, draw the tangent F*d*, cutting the line DA in *d*. Then the velocity at A is to that at F as AB to *d*F. Hence also we see that the velocities in every point of the curve are proportional to the portion of the tangents at those points which are intercepted between *any* two lines parallel to AD.

Either of these methods for ascertaining the velocity, in this case of parallel deflections, will in general be easier than the general method in No. 121, by the equicurve circle.

It was thus that Galileo discovered the parabolic motion of heavy bodies.

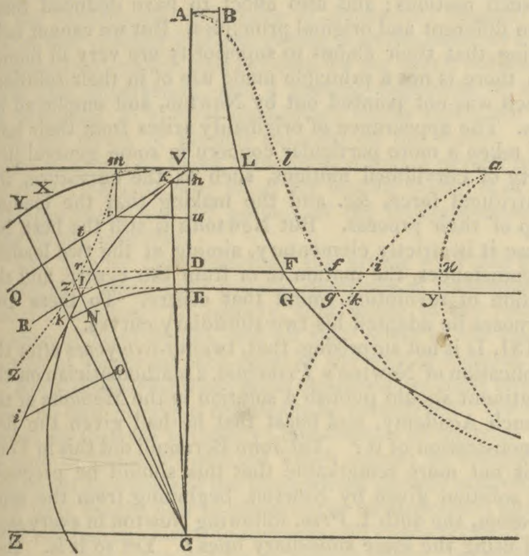
2. We must consider the motions of bodies affected by centripetal or centrifugal forces, always tending to one fixed point. This is the celebrated *inverse problem of centripetal forces*, and is the forty-second proposition of the first book of Newton's *Principia*. We shall give the solution after the manner of its illustrious author, because it is elementary in the purest sense of the word, keeping in view the two leading circumstances, and these only, namely, the motion of approach and recess from the centre, and the motion of revolution. By this judicious process, it becomes a pattern by which more refined, and, in some respects, better solutions should be modelled. At the same time we shall supply some steps of the investigation which his elegant conciseness has made him omit.

125. Let a body which tends to C (fig. 28) with a force proportional to the ordinates of the exponent BLFG, having the axis CA, be projected from V in the direction VQ, with the velocity which the centripetal force would generate in it by accelerating it along AV. It is required to determine the path or orbit VIKI of the body, and its place I in this orbit, at the end of the assigned time T.

Suppose the thing done, and that I is the place of the body. About the centre C, with the distances CV and CI, describe the circles YV and ID. Draw CIX to the circumference, and draw the ordinate DF of the exponent of forces, producing it toward x, and produce the ordinate VL toward a. Let Vt be the distance to which the body would go along the tangent VQ in the time T, and join tC. Let this be supposed done for every point of the curve. Let aik and axy be two curves so related to the curve VIK, that the ordinate DF cuts off an area V$ai$D equal to the orbital sector VCI, and an area V$ax$D equal to the circular sector VCX.

Then, because the velocity of projection is given, the distance V*t* is known, and the area of the triangle VC*t*. But this is equal to the area VCI, by the laws of central forces. (No. 115.) Therefore the area V*ai*D is given. Also, because the area VCI increases in the proportion of the time, the area V*ai*D increases at the same rate.

Fig 28.



Therefore, having these subsidiary curves *aik*, *axy*, the problem is solved as follows:

Draw an ordinate D*i*, cutting off an area V*ai*D proportional to the time, and describe a circle DIR. Then draw a line CX, cutting off a sector VCX, equal to the area V*ax*D cut off by the ordinate D*ix*. This line will cut the circle DR in the point I, which is the point of the orbit that was demanded.

But the chief difficulty of the problem consists in the description of the two subsidiary curves *aik* and *axy*, into which the lines VIK and VXY are transformed. We attain this construction by resolving the motion in the arch of the orbit into two motions, one of which is in the direction of the transverse force, or of the radius vector, and the other is in the direction of revolution, or perpendicular to the radius.

Let V*k* and IK be two very small arches described in equal moments, and therefore ultimately in the ratio of the velocities in V and I (No. 73). Describe the circle KE, cutting IC in N. Draw KC and *k*C, and *kn* perpendicular to VC.

The element ICK of the orbit is $= \frac{\mathrm{IC} \times \mathrm{KN}}{2}$, or to $\frac{1}{2}\mathrm{IC} \times \mathrm{KN}$. This is equal to the element D*ik*E of the area V*ai*D, or to D*i* × DE, or to D*i* × IN. Therefore $\mathrm{IN} : \mathrm{KN} = \frac{1}{2}\mathrm{IC} : \mathrm{D}i$, or $2\mathrm{IN} : \mathrm{KN} = \mathrm{IC} : \mathrm{D}i$, and $\mathrm{D}i = \frac{\mathrm{IC} \times \mathrm{KN}}{2\mathrm{IN}}$.

Now let A*lfgh* be the exponent of the velocities, that is (No. 86), let Vl^2 be to Df^2 as ABLV to ABFD, or V*l* : D*f* = $\sqrt{\mathrm{ABLV}} : \sqrt{\mathrm{ABFD}}$. Make V*v* and I*i* in the tangents respectively equal to V*l* and D*f*. Draw *vu* and *i*O perpendicular to VC and IC, and *vm* perpendicular to LV produced. Let *mrz* be an equilateral hyperbola, having VC, ZC, for its asymptotes, and cutting FD produced in *r*. Then the ordinates V*m*, D*r*, are inversely proportional to CV, CD, or V*m* : D*r* = CD : CV, = CI : CV. But because the momentary sectors VC*k* and ICK are equal, *kn* : KN = CI : CV. Therefore,

$$\mathrm{V}m : \mathrm{D}r = kn : \mathrm{KN};$$

$$\text{but } \mathrm{V}v : \mathrm{V}m = \mathrm{V}k : kn,$$

$$\text{and } \mathrm{I}i \text{ (or } \mathrm{D}f) : \mathrm{V}v = \mathrm{IK} : \mathrm{V}k,$$

$$\text{therefore } \mathrm{I}i : \mathrm{D}r = \mathrm{IK} : \mathrm{KN};$$

$$\text{but } \mathrm{I}i : i\mathrm{O} = \mathrm{IK} : \mathrm{KN}, \text{ by sim. triang.}$$

$$\text{therefore } \mathrm{D}r = i\mathrm{O}, \text{ and } i\mathrm{O} : \mathrm{V}m = \mathrm{VC} : \mathrm{CI}.$$

Also, by similarity of triangles, IO : *i*O = IN : KN, and 2IO : *i*O = 2IN : KN.

Now it was shown, that in order that the space D*ik*E may be equal to the space ICK, we must have

$$2\mathrm{IN} : \mathrm{KN} = \mathrm{IC} : \mathrm{D}i,$$

$$\text{or } 2\mathrm{IO} : i\mathrm{O} = \mathrm{IC} : \mathrm{D}i;$$

$$\text{but } i\mathrm{O} : \mathrm{V}m = \mathrm{VC} : \mathrm{IC},$$

$$\text{therefore } 2\mathrm{IO} : \mathrm{V}m = \mathrm{VC} : \mathrm{D}i,$$

$$\text{and } \mathrm{D}i = \frac{\mathrm{VC} \times \mathrm{V}m}{2\mathrm{IO}}.$$

Having obtained D*i*, we easily get D*x*; for the ultimate ratio of ICK to XCY is that of IC^2 to VC^2. Therefore make

$$\mathrm{IC}^2 : \mathrm{VC}^2 = \mathrm{D}i : \mathrm{D}x.$$

Thus are the points of the two subsidiary curves *aik*, *axy*, determined.

The rectangle VC × V*m* is a constant magnitude, and is given because VC is given, and V*m* is the given velocity V*l*, diminished in the ratio of radius to the sine of the given angle CVQ.

But the line 2IO is of variable magnitude; but it is also given by means of known quantities. IO^2 is $= \mathrm{I}i^2 - i\mathrm{O}^2$, $= \mathrm{D}f^2 - \mathrm{D}r^2$, and $\mathrm{IO} = \sqrt{\mathrm{D}f^2 - \mathrm{D}r^2}$. Moreover, $\mathrm{D}f^2 = \mathrm{ABFD}$, and $\mathrm{D}r^2 = \frac{\mathrm{VC}^2 \times \mathrm{V}m^2}{\mathrm{IC}^2}$. Therefore $2\mathrm{IO} = 2\sqrt{\mathrm{ABFD} - \frac{\mathrm{VC}^2 \times \mathrm{V}m^2}{\mathrm{IC}^2}}$, expressed in known quantities, because ABFD is known from the nature of the centripetal force.

Let the indeterminate distance CI or CD be $= x$, and let the ordinate DF, expressing the force, be *y*. Let VC be *a*, and V*m* be *c*, and let *ab* be a rectangle equal to the whole area of the exponent of force lying between the ordinate AB and the ordinate CZ, so that $ba - \int y dx$ may represent the indeterminate area ABFD.

$$\text{We have } \mathrm{D}i = \frac{ac}{2\sqrt{ab - \int y dx - \frac{a^2 c^2}{x^2}}}$$

$$\text{and } \mathrm{D}x = \frac{a^3 c}{2x^2\sqrt{ab - \int y dx - \frac{a^2 c^2}{x^2}}}.$$

Remark.—We have hitherto supposed that the velocity of projection is acquired by acceleration along AV. But this was merely for greater simplicity of argument, and that the final values of D*i* and D*x* might be easier conceived. In whatever way the velocity is acquired, it will still be true, that when in any point V we make V*l* to V*m* as the momentary increment V*k* of the arch is to the perpendicular *kn* on the radius vector, we shall have in every other point, such as I, the line D*f* to the line D*r* as the increment IK of the arch to KN. And in the final equation D*f* will still be expressed by $\sqrt{ab - \int y dx}$.

126. *Cor.* 1. The angle which the path of the projectile makes with the radius vector is determined by this solution; for I*i* is to *i*O as radius to the sine of this angle; which sine is therefore $= \frac{ac}{x\sqrt{ab - \int y dx}}$.

Apsides determined;

127. *Cor.* 2. When the magnitude $\frac{ac}{x}$ is equal to $\sqrt{ab - \int y dx}$, the path is perpendicular to the radius vec-

tor, and the body is at one of the apsides of its orbit, and begins to recede from the centre after having approached to it, or begins to approach after having receded.

and curvature.

128. *Cor.* 3. The curvature of the orbit VIK is also determined in every point; for the curvature of any line is inversely as the radius of the equicurve circle, and this is to the chord which passes through C as radius to the sine of the angle CI*i*. Because the velocity in any point I is $= \sqrt{\text{ABFD}}$, and is equal to what the centripetal force at I would produce, by impelling the body along one fourth of the deflective chord of the equicurve circle, we have this chord $= 4\,\frac{\text{ABFD}}{\text{DF}}$. Or we obtain it by taking a third proportional to the momentary deflection and the momentary arch of the curve, or by other processes of the higher geometry, all proceeding on the quantities furnished in this investigation.

Newton the inventor.

129. Such is the solution of this celebrated problem given by Sir Isaac Newton, who may justly be called the inventor of the science of which it is the chief result, as well as of the geometry by help of which it is prosecuted. For we cannot give this glory to Galileo; for his simple problem of the motion of bodies affected by uniform and parallel gravity, however just and elegant his solution may be, was peculiar; and the same must be said of Mr Huygens's doctrine of centrifugal forces. Besides, these theorems had been investigated by Newton several years before, *suâ mathesi facem preferente*, as corollaries which he could not pass unnoticed, from his general method. This is proved by letters from Huygens. Newton's investigation is extremely but elegantly concise, and is one of the best exertions of his sagacious mind.

History of this problem.

130. Whether we consider this problem as a piece of mere mathematical speculation, or attend to its consequences, which include the whole of the celestial motions in all their extent and complication, we must allow it to be highly interesting, and likely to have engaged much attention in the period of ardent inquiry which closed the last century. Accordingly, it was no sooner known, by the publication of the *Mathematical Principles of Natural Philosophy* in 1686, than it occupied the talents of the most eminent mathematicians; and many solutions were published, some of which differ considerably from Newton's, and some are more expeditious, and better fitted for computation. Of these, the most remarkable for originality and ingenuity are those of De Moivre, Hermann, Keill, and Stewart. The last differs most from the methods pursued by others. M'Laurin's propositions on this subject, and in that part of his fluxions which treats of curvature, are highly valuable, classing the chief affections of curvilineal motions geometrically, as they are suggested by the fluxionary method; and then showing, in a very instructive manner, the connection between these mathematical affections of motion and the powers of nature which produce them. This part of his excellent work is a fine example of the real nature of all inquiries in dynamics, showing that it differs from geometry little more than in the language, in which the word *force* is substituted for *acceleration*, *retardation*, or *deflection*. We recommend the careful perusal of these propositions to all who wish to have clear conceptions of the subject. Dr John Keill and Dr Horsley (bishop of Rochester) have given particular treatises on the motions of bodies deflected by centripetal forces inversely proportional to the cubes of the distances; induced by the singular motions which result from this law of action, and the multitude of beautiful propositions which they suggest to the mathematician. Newton, indeed, first perceived both of these peculiarities, and has begun this branch of the general problem. He first demonstrated the description of the logarithmic and hyperbolic spirals, and indicated a variety of curious recurring elliptical spirals, which would be described by means of this force, showing that they are all susceptible of accurate quadrature. Several of those authors affect to consider their solutions as more perfect than Newton's, and as more immediately indicating the remarkable properties of such motions; and also affect to have deduced them from different and original principles. But we cannot help saying that their claims to superiority are very ill founded; there is not a principle made use of in their solutions which was not pointed out by Newton, and employed by him. The appearance of originality arises from their having taken a more particular concern in some general property of curvilineal motions, such as the curvature, the centrifugal force, &c. and the making that the leading step of their process. But Newton's is still the best, because it is strictly elementary, aiming at the two leading circumstances, the motion to or from the centre, and the motion of revolution round that centre. To these two purposes he adapted his two subsidiary curves.

Singul boast John noulli.

131. Is it not surprising, that, twenty-five years after the publication of Newton's *Principia*, a mathematician on the Continent should publish a solution in the Memoirs of the French Academy, and boast that he had given the first demonstration of it? Yet John Bernoulli did this in 1710 Is it not more remarkable that this should be precisely the solution given by Newton, beginning from the same theorem, the 40th I. *Prin.* following Newton in every step, and using the same subsidiary lines? Yet so it is. Bernoulli actually reduces the whole to two functions, namely,

$$\frac{ac}{\sqrt{ab - \int \varphi dx - \frac{a^2c^2}{x^2}}} \text{ and } \frac{a^2c}{\sqrt{abx^4 - x^4\int \varphi dx - a^2c^2x^2}};$$

which last is plainly the same with Newton's

$$\frac{\text{Q} \times \text{CX}^2}{\text{A}^2\sqrt{\text{ABDF} - \text{Z}}};$$

because Newton's $\frac{\text{Q}}{\text{A}}$ is the same with $\frac{ac}{x}$, and Newton's $\text{A}^2\sqrt{\text{ABFD} - \text{Z}^2}$ is the same with

$$x^2\sqrt{ab - \int \varphi dx - \frac{a^2c^2}{x^2}},$$

which Bernoulli has changed into

$$\sqrt{abx^4 - x^4\int \varphi dx - a^2c^2x^2}.$$

Bernoulli's chief boast in this dissertation is, that *now* philosophers may be assured that the planets will always describe conic sections; a truth of which they had not as yet received any proof; because, says he, Newton's argument for it in the corollary of the 13th proposition is inconclusive, and because he had not been able to accommodate his demonstration of the 41st and 42d propositions to the particular case of the planetary gravitation. Newton's demonstration in the corollary of the 13th proposition is just founded on the principle on which the very demonstration of the 42d, adopted by Bernoulli, proceeds, and without which that demonstration is of no force; namely, that a body, in given circumstances of situation, velocity, direction, and centripetal force, can describe no other figure than what it really describes. Newton did not accommodate the demonstration of the 42d proposition to the planetary motions, because he had already demonstrated the nature of their orbits; but mentions the case of a force proportional to the reciprocal of the cubes of their distance, not as a deduction from the 42d, but because it *was not* a deduction from it, and admitted a very singular and beautiful investigation by methods totally and essentially different.

Co lusion.

132. It cannot be expected that, in the narrow limits prescribed to a work like ours, we can proceed to consider the various departments of this celebrated problem. We are only giving the outlines of the general doctrines of dynamics; and we have bestowed more time on those which are purely elementary than some readers may think they deserve. We were anxious to give just conceptions of the fundamental principles of dynamics; because we know that nothing else can entitle it to the name of a demonstrative science, and because we see much indistinctness and uncertainty, and a general vagueness or want of precision, in several elementary works which are put into the hands of persons entering on the study. This leads to errors of more consequence than a person is apt to think; because they affect our leading thoughts of mechanism itself, and our notions of the intimate nature of the visible universe.

U versal re ction is a v of the m erial w d.

133. But we must conclude the article with this great problem. Many very general doctrines of dynamics remain untouched; all, namely, that relate to the rotative motion of rigid bodies, and all that relate to the mutual action of bodics on each other in the way of impulse.

Notwithstanding these great omissions, we must observe that no new principle remains to be considered. We have given all that are necessary; and there is no question that occurs in the cases omitted which cannot be completely answered by means of the propositions already established. We have taught how to discover the existence and agency of a mechanical force, to measure and characterize it, and then to state what will be its various effects, according to the circumstances of the case.

134. Proceeding by these principles, men have discovered an universal fact, that every *action* of one body on another is accompanied by an equal *re-action* of that other on the first in the opposite direction; that is, to express it in the language of dynamics, "all the phenomena which make us infer that the body A possesses a force by which it changes the motion of the body B, show, at the same time, that B possesses a force by which it makes an equal and opposite alteration in the motion of A." This, however, is not a doctrine of abstract dynamics; it docs not flow from our idea of force; therefore it was not included in our list of the *laws of motion.* It is a part of the mechanical history of nature, just as the law of universal gravitation is; and it might be called the law of *universal re-action.* Sir Isaac Newton has, in our humble apprehension, deviated from his accustomed logical accuracy, when he admits, as a third *axiom* or law of motion, that re-action is always equal and contrary to action. It is a physical law, in as far as it is *observed* to obtain through the whole extent of the solar system. But Newton himself did not, in the subsequent part of his noble work, treat it as a logical axiom; that is, as a law of human thought with respect to motion; for he labours with much solicitude, and with equal sagacity, to prove, by *fact and observation,* that it really obtains through the whole extent of the solar system; and it is in this discovery that his chief claim to unequalled penetration and discernment appears.

pulsion lained t,

135. Availing ourselves of this fact, we, with very little trouble, state all the laws of impulsion. The body A, for example, moving to the westward at the rate of eight feet per minute, overtakes the double body B, moving at the rate of four feet per minute. What must be the consequence of their impenetrability, and of the equality and contrariety of action and re-action? Their motions must be such that both sustain equal and opposite changes. They must give, in some way or other, *this* indication of possessing equal and opposite forces. This will be the case if, when the changes are completed, A and B move on in contact at the rate of four feet per minute; for here A has produced in each half of B a change of motion two, and therefore a totality of change equal to four. This is the effect, the mark, the measure of the *impulsive* force of A; for it is the whole *impulsion.* B has produced in A a change of motion four, equal to the former, and in the opposite direction. This is the effect, mark, and measure of the *repulsive* force of A; for it is the whole *repulsion.* And this is all that we observe in the collision of two lumps of clay; and the observation is one of the facts on which the reality of the physical law of equal action and re-action is founded; and we can make no further inference from *this* fact.

Conclusion.

But the event might have been very different. A and B may be two magnets floating on corks on water, with their north poles fronting each other. We know, by other means, that they really possess forces by which they equally repel each other. The dynamical principles already established tell us also what must happen in this case. That both conditions of equal re-action and sensible repulsion may be fulfilled, A must come to rest, and B must move forward at the rate of four feet per minute. The same thing must happen in the meeting of perfectly elastic bodies, such as billiard balls. If elasticities are known to be imperfect in any degree, our dynamical principles will still state the effect of their collision in conformity to the law of equal reaction.

and rotation.

136. In like manner, all the motions of rotation are explained or predicted by means of the same principles of dynamics applied to the force of cohesion. This is considered as a moving force, because, when the attraction of a magnet acts on a bit of iron attached to one end of a long lath floating on water, the whole lath is moved, although the magnet does not act on it at all; some other force acts on it; it is its cohesion, which is therefore a moving force, and the subject of dynamical discussion.

137. And thus it appears that these subjects do not come necessarily, nor perhaps with scientific propriety, under the category of dynamics, but are parts of the mechanical history of nature. Yet, did a work like ours give room in this place, the study of mechanical nature might be considerably improved, by giving a system of such *general* doctrines as involve no other notions but those of force and its measures, and the hypothesis of equal re-action. Some very general, nay universal, consequences of this combination might be established, which would greatly assist the mechanician in the solution of difficult and complicated problems. Such is the proposition, that *the mutual actions of bodies depend on their relative motions only, and require no knowledge of their real motions.* This principle simplifies in a wonderful manner the most difficult and the most frequent cases of action which nature presents to our view; but at the same time gives a severe blow to human vanity, by forcing us to acknowledge that we know nothing of the real motion of any thing in the universe, and never shall know any thing of it, till our intellectual constitution, or our opportunities of observation, are completely changed.

138. M. d'Alembert had made this principle still more serviceable for extricating ourselves from the immense complication of actions that occurs in all the spontaneous phenomena of nature, by presenting it to us in a different form, which more distinctly expresses what may be called the *elements* of the actions of bodies on each other. His proposition is as follows (see his *Dynamique*, page 73):

D'Alembert's general principle of dynamics.

"In whatever manner a number of bodies change their motions, if we suppose that the motion which each body would have in the following moment, if it were perfectly free, is decomposed into two others, one of which is the motion which it really takes in consequence of their mutual actions, the other will be such, that if each body were impressed by this force alone (that is, by the force which would produce this motion), the whole system of bodies would be in equilibrio."

This is almost self-evident; for if these second constituent forces be not such as would put the system in equilibrio, the other constituent motions could not be those which the bodies really take by the mutual action, but would be changed by the first.

For example, let there be three bodies P, Q, R, and let the forces A, B, C, act on them, such as would give them the velocities p, q, r, in any directions whatever, producing the momenta, or quantities of motion, $P \times p$, $Q \times q$, $R \times r$, which we may call A, B, C, because they are the proper measures of the moving force. Let us moreover suppose, that, by striking each other, or by being any how connected with each other, they cannot take these motions, A, B, and C, but really take the motions a, b, and c. It is plain that we may conceive the motion A impressed on the body P, to be composed of the motion a, which it really takes, and of another motion α. In like manner, B may be resolved into b, which it takes, and another β; and C into c and $\varkappa$. The motions will be the same, whether we act on P with the force A, or with the two forces a and α; whether we act on Q with the force B, or with b and β; and on R with the force C, or with c and $\varkappa$. Now, by the supposition, the bodies actually take the motions a, b, and c; therefore the motions α, β, and $\varkappa$, must be such as will not derange the motions a, b, and c; that is to say, that if the bodies had only the motions α, β, and $\varkappa$, impressed on them, they would destroy each other, and the system would remain at rest.

M. d'Alembert has applied this proposition with great address and success to the very difficult questions that occur in the motions and actions of fluids, and many other most difficult problems, such as the precession of the equinoxes, &c. The cause of its utility is, that in most cases it is not difficult to find what forces will put a system in equilibrio; and, combining these with the known extraneous forces whose effects we are interested to discover, we obtain the motions which really follow the mutual action of the bodies.

This is not, properly speaking, a principle; it is a form in which a general fact may be conceived. In the same way the celebrated mathematician De la Grange observed, that a system of bodies, acting on each other in any way, is in equilibrio, if there be impressed on its parts forces in the inverse proportion of the velocities which each body takes in consequence of their action or connection; and he expresses this universal fact by a very simple formula; and, calling this also a principle, he solves every question with ease and neatness, by reducing it to the investigation of those velocities. In this way he has written a complete system of dynamics, to which he gives the title of *Méchanique Analytique*, full of the most ingenious and elegant solutions of very interesting and difficult problems; and all this without drawing a line or figure, but accomplishing the whole by algebraic operations.

But this is not teaching mechanical philosophy; it is merely employing the reader in algebraic operations, each of which he perfectly understands in its quality of an algebraic or arithmetical operation, and where he may have the fullest conviction of the justness of his procedure. But all this may be (and, in the hands of an expert algebraist, it generally is), without any notions, distinct or indistinct, of the things or the process of reasoning that are represented by the symbols made use of. (B. B. B.)

DYNANOMETER, an instrument for ascertaining the relative strength of men and animals.* Of an instrument of this kind, invented by Regnier, and of which a description is given in the *Journal de l'Ecole Polytéchnique*, tom. ii. the author thus speaks: "Some important knowledge might be acquired, had we the easy means of ascertaining, in a comparative manner, our relative strength at the different periods of life, and in different states of health. Buffon and Guéneau, who had some excellent ideas on this subject, requested me to endeavour to invent a portable machine, which, by an easy and simple mechanism, might conduct to a solution of this question, on which they were then engaged. These philosophers were acquainted with that invented by Graham, and improved by Dr Desaguliers, at London; but this machine, constructed of wooden work, was too bulky and heavy to be portable; and, besides, to make experiments on the different parts of the body, several machines were necessary, each suited to the part required to be tried. They were acquainted also with the dynanometer of citizen Leroy of the Academy of Sciences at Paris. It consisted of a metal tube ten or twelve inches in length, placed vertically on a foot like that of a candlestick, and containing in the inside a spiral spring, having above it a graduated shank terminating in a globe. This shank, together with the spring, sunk into the tube in proportion to the weight acting upon it, and thus pointed out, in degrees, the strength of the person who pressed on the ball with his hand.

"This instrument, though ingenious, did not appear sufficient, however, to Buffon and Guéneau; for they wished not merely to ascertain the muscular force of a finger or hand, but to estimate that of each limb separately, and of all the parts of the body. I shall not here give an account of the attempts I made to fulfil the wishes of these two philosophers, but only observe, that in the course of my experiments I had reason to be convinced that the construction of the instrument was not so easy as might have been expected. Besides the use which an enlightened naturalist may make of this machine, it may be possible to apply it to many other purposes. For example, it may be employed with advantage to determine the strength of draught cattle; and, above all, to try that of horses, and compare it with the strength of other animals. It may serve to make known how far the assistance of well-constructed wheels may favour the movement of a carriage, and what is its *vis inertiæ* in proportion to the load. We might appreciate by it, also, what resistance the slope of a mountain opposes to a carriage, and be able to judge whether a carriage is sufficiently loaded in proportion to the number of horses that are to be yoked to it. In the arts, it may be applied to machines of which we wish to ascertain the resistance, and when we are desirous to calculate the moving force that ought to be adapted to them. It may serve, also, as a Roman balance to weigh burdens. In short, nothing would be more easy than to convert it into an anemometer, to discover the absolute force of the wind, by fitting to it a frame of a determined size filled up with wax cloth; and it would not be impossible to ascertain by this machine the recoil of fire-arms, and consequently the strength of gunpowder.

"This dynanometer, in its form and size, has a near resemblance to a common graphometer. It consists of a spring twelve inches in length, bent into the form of an ellipsis; from the middle of which arises a semicircular piece of brass, having engraved upon it the different degrees that express a force of the power acting on the spring. The whole of this machine, which weighs only two pounds and a half, opposes, however, more resistance

Eadmerus.

than may be necessary to determine the action of the strongest and most robust horse."

DYNASTY, among ancient historians, signifies a race or succession of kings of the same family or line. Such were the dynasties of Egypt. The word is formed from the Greek δυναστεια, of δυνατεω, *to be powerful.*

DYSÆ, in *Mythology*, inferior goddesses among the Saxons, being the messengers of the great Odin, whose province it was to convey the souls of such as died in battle to his abode, called *Valhalla* or the hall of slaughter, where they were to drink, with him and their other gods, *cerevisia*, a kind of malt liquor, in the skulls of their enemies. The *Dysæ* conveyed those who died a natural death to *Hela*, the goddess of hell, where they were tormented with hunger, thirst, and every kind of evil.

DYSART, a royal burgh of Scotland, in the county of Fife, is situated on the coast of the Frith of Forth, about a mile to the eastward of Kirkaldy. It consists of three narrow streets, with a species of square in the centre. In the principal street there are a number of antique houses, the fronts of which are generally decorated with inscriptions and dates. Formerly this town enjoyed a considerable trade, and on this account was ennobled with the popular name of "Little Holland." The state of trade now, however, is far from corresponding with that ambitious title. The principal article manufactured is salt, which, together with coal, is exported in quantities. The weaving of checks, ticks, and similar fabrics, is also carried on, and affords employment to a number of the inhabitants. The harbour of the town is tolerably good. Dysart was erected into a royal burgh in the beginning of the sixteenth century, and is at present governed by two bailies, a treasurer, and twenty-two councillors. Besides the parish church, there is a congregation connected with the Relief body. The town possesses a news-room and a mechanics' institution. The population of the burgh and parish amounted in 1821 to 6529, and in 1831 to 7104.

DYSCRASY, among physicians, denotes an ill habit or state of the humours, as in the scurvy, jaundice, and other diseases.

DYSENTERY, in *Medicine*, a diarrhœa or flux, wherein the stools are mixed with blood, and the bowels miserably tormented with gripes. See MEDICINE.

DYSOREXY, among physicians, denotes a want of appetite, proceeding from a weakly stomach.

DYSPEPSY, a difficulty of digestion.

DYSPNŒA, a difficulty of breathing, usually called *asthma.*

DYVOUR, in *Scotch Law*, otherwise *Bare-man*, a person who, being involved in debt, and unable to pay the same, makes cession of his effects in favour of his creditors. The word is used in the same sense as BANKRUPT.

E.

E, the second vowel, and fifth letter of the alphabet. This letter is most probably derived from the old character in the ancient Hebrew and Phœnician alphabets, reversed by the Greeks to this position, E, not from the Hebrew ה, as some have supposed. From the same origin is also derived the Saxon *e*, which is the first letter in their alphabet that differs from the Latin one. It is formed by a narrower opening of the larynx than the letter A; but the other parts of the mouth are used nearly in the same manner as in that letter. E has a long and short sound in most languages. The short sound is audible in *bed, fret, den*, and other words ending in consonants; the long sound is produced by a final *e*, or an *e* at the end of words, as in *glebe, here, hire, scene, sphere, interfere, revere, sincere*, and the like, in most of which it sounds like *ee*. In some other cases, this letter, by coming after *i*, is long, as in *believe, chief, grief, reprieve;* and sometimes the long sound is expressed by *ee*, as in *bleed, beer, creed*, and so on. Sometimes the final *e* is silent, and only serves to lengthen the sound of the preceding vowel, as in *rag, rage, stag, stage, hug, huge.* The sound of *e*, however, is obscure in the following words: *oxen, heaven, bounden, fire, massacre, maugre*, and other words. The Greeks have their long and short *e*, which they call *epsilon* ε, and *êta* η. The French have several kinds of *e;* the Latins have likewise a long and short *e*. In some instances the latter also write *e* instead of *a*, as *dicem* for *dicam*; and this is no doubt the reason why *a* is so often changed into *e* in the preter-perfect tense, as *ago, egi; facio, feci*, and the like.

As a numeral, E stands for 250, according to the verse,

> E, quoque ducentos et quinquaginta tenebit.

In music it denotes the tone *e-la-me;* in the calendar it is the fifth of the dominical letters; and in sea charts it distinguishes all the easterly points. In ancient contractions and abbreviations E represents *Est, Ennius, Edilis;* EB, *Ejus Bona;* ED, *Ejus Domus;* EE, *Ejus Ætas;* EF, *Ejus Filius;* and so on.

EACHARD, JOHN, an English divine of great learning and wit in the seventeenth century, was bred at Cambridge, and was the author of *The Grounds and Occasions of the Contempt of the Clergy and Religion inquired into*, 1670. In 1675 he was chosen master of Catharine Hall upon the decease of Dr John Lightfoot; and the year following was created doctor in divinity by royal mandate. He died in 1697.

EACHARD, *Laurence*, an eminent English historian of the eighteenth century, was nearly related to Dr John Eachard. He was the son of a clergyman, who, by the death of his elder brother, became master of a good estate in Suffolk. He was educated in the university of Cambridge, entered into holy orders, and was presented to the living of Welton and Elkington in Lincolnshire, where he spent above twenty years of his life, and distinguished himself by his writings, especially his History of England, which was attacked by Dr Edmund Calamy and by Mr John Oldmixon. His *General Ecclesiastical History, from the Nativity of Christ to the first Establishment of Christianity by Human Laws under the Emperor Constantine the Great*, has passed through several editions. He was installed as archdeacon of Stowe and prebendary of Lincoln in 1712. He died in 1730.

EADMERUS, EADMER, or EDMER, an esteemed historian, was an Englishman by birth, but his parents, and the particular time and place of his nativity, are not known. He received a learned education, and early discovered a taste for history, by recording every remarkable event which came to his knowledge. Being a monk in the cathedral of Canterbury, he had the happiness to become the bosom friend and inseparable companion of two arch-

Eagle.

bishops of that see, St Anselm and his successor Ralph. To the former of these he was appointed spiritual director by the pope; and that prelate did nothing without his approbation. In the year 1120 he was sent for by King Alexander I. of Scotland, to be raised to the primacy of that kingdom; and having obtained leave of King Henry and the Archbishop of Canterbury, he departed for Scotland, where he was kindly received by the king, and on the third day after his arrival elected bishop of St Andrews; but on the day after his election a dispute unfortunately arose between the king and him, in a private conference about his consecration. Eadmerus having been a constant companion of two archbishops of Canterbury, was a violent stickler for the prerogatives of that see; and therefore told the king that he was determined to be consecrated by none but the Archbishop of Canterbury, whom he believed to be the primate of all Britain. Alexander, who was naturally a fierce prince, and supported the independence of his crown and kingdom with great spirit, was so much offended that he broke off the conference in a violent passion, declaring that the see of Canterbury had no pre-eminency over that of St Andrews. This breach between the king and the bishop-elect became daily wider, until at length Eadmerus, despairing of recovering the royal favour, sent his pastoral ring to the king; laid his pastoral staff upon the high altar, whence he had taken it; and abandoning his bishopric, returned to England. He was kindly received by the Archbishop and clergy of Canterbury, though they disapproved of his stiffness, and thought him too hasty in forsaking the honourable station to which he had been called. Nor was it long before Eadmerus became sensible of his error, and desirous of correcting it. With this view he wrote a long submissive letter to the king of Scotland, entreating his leave to return to the bishopric, and promising compliance with his royal pleasure in every thing respecting his consecration; which letter was accompanied by an epistle to the same purpose from the archbishop. These overtures, however, which were made in the year 1122, did not produce the desired effect. But Eadmerus is most worthy of the grateful remembrance of posterity for his historical works, particularly for his history of the affairs of England in his own time, from the year 1066 to the year 1122; a work in which he has inserted many original papers, and preserved many important facts which are nowhere else to be found. This work has been highly commended for its authenticity, as well as for regularity of composition and purity of style. It is indeed more free from legendary tales than any other work of this period; and it is impossible to peruse it with attention, without conceiving a favourable opinion of the learning, good sense, sincerity, and candour of its author.

EAGLE. See ORNITHOLOGY.

EAGLE, in *Heraldry*, is accounted one of the most noble bearings in armory, and, according to the learned in this science, ought to be given to none but such as greatly excel in the virtues of generosity and courage, or have rendered singular service to their sovereigns; in which case they may be allowed a whole eagle, or an eagle naissant, or only the head or such other parts as may be judged most agreeable to their exploits.

The eagle has been borne as an ensign or standard by several nations. The first who seem to have assumed the eagle were the Persians, according to the testimony of Xenophon; but subsequently it was adopted by the Romans, who, after a great variety of standards, at length fixed on the eagle, in the second year of the consulate of C. Marius, having till that period used indifferently wolves, leopards, and eagles, according to the humour of the commander. The Roman eagles, it must be observed, were not painted on a cloth or flag, but were figures in relief, formed of silver or gold, and borne on the tops of pikes; the wings being displayed, with frequently a thunderbolt in the talons. Under the eagle on the pike were piled bucklers, and sometimes crowns.

Constantine is said to have been the first who introduced the eagle with two heads, to intimate, that though the empire seemed divided, it had yet only one body. Others say that it was Charlemagne who resumed the eagle as the Roman ensign, and added to it a second head; but that opinion is destroyed by an eagle with two heads, observed by Lipsius on the column of Antoninus, as also by the eagle's having only one head on the seal of the golden bull of the Emperor Charles IV. The conjecture, therefore, of Menestrier appears more probable; namely, that the emperors of the East, when there were two on the throne at the same time, struck their coins with the impression of a cross with a double traverse, which each of them held in his hand, as being the symbols of the Christians; and that they did the like with the eagle in their ensigns, and instead of doubling, joined them together, representing them with two heads; a practice in which they were followed by the emperors of the West. But this conjecture of Menestrier is not confirmed by ancient coins, without which Papebroche inclines to think the use of the eagle with two heads to have been merely arbitrary, though he admits it to be probable that it was first introduced on occasion of there being two emperors on the same throne.

The eagle on medals is, according to Spanheim, a symbol of divinity and providence, and, according to all other antiquaries, of empire. The princes on whose medals it is most usually found are the Ptolemies, and the Seleucidæ of Syria. An eagle with the word *consecratio* expresses the apotheosis of an emperor.

EAGLE, in *Astronomy*, is a constellation of the northern hemisphere, having its right wing contiguous to the equinoctial. See AQUILA.

White EAGLE, is a Polish order of knighthood, instituted in 1325 by Vladislaus V. on marrying his son Casimir to a daughter of the grand duke of Lithuania. The knights of this order were distinguished by a gold chain which they wore on the stomach, and to which was suspended a silver eagle crowned.

Black EAGLE, a similar order instituted in 1701 by the elector of Brandenburg, on his being crowned king of Prussia. The knights of this order wore an orange-coloured ribbon, to which was suspended a black eagle.

EAGLE ISLAND, an island in the South Pacific Ocean, near the north-east coast of New Holland, between Lizard Island and Cape Flattery. Lat. 14. 32. S.

EAGLES, a name frequently found in the ancient histories of Ireland, and used to express a sort of base money which was current in that kingdom in the early part of the reign of Edward I. that is, about the year 1272. There were, besides the eagles, lionines, rosades, and many other coins of the same sort, named according to the figures they were impressed with.

The current coin of the kingdom at that time was a composition of copper and silver, in determinate proportions; but these were so much inferior to the standard proportion of that time, that they were not intrinsically worth half so much as the others. They were imported from France and other foreign countries. When Edward had been a few years established on the throne, he set up mints in Ireland for coining good money, and then decried the use of eagles, and other kinds of base coin, making it death, with confiscation of effects, to import any more of them into the kingdom.

EAGLET, a diminutive of eagle, properly signifying a young eagle. In heraldry, when there are several eagles on the same escutcheon, they are termed *eaglets*.

EALDERMAN, or Ealdorman, among the Saxons, was of the same import with earl among the Danes. The word was also used for an elder, senator, or statesman; and hence, at this day, we call those functionaries *aldermen* who are associates to the chief officer in the common council of a city or corporate town.

EALING, a town of the county of Middlesex, five miles and a half from London, divided into two parts, distinguished by the names of East and West Ealing. It is in the hundred of Ossulston, and the parish includes the town of Old Brentford. It contains a handsome modern church, and several chapels for separatists, with some elegant villas. The population amounted in 1801 to 5035, in 1811 to 5361, in 1821 to 6608, and in 1831 to 7783.

EAR. (See Anatomy.) The ear has its beauties, which a good painter ought by no means to disregard; and where it is well formed it would be an injury to the head were it hidden. Suetonius insists particularly on the beauty of Augustus's ears; and Ælian, describing the beauties of Aspasia, observes that she had short ears. Martial also ranks large ears amongst the number of deformities. Amongst the Athenians it was a mark of nobility to have the ears bored or perforated; but amongst the Hebrews and Romans this was a type of servitude.

Ear, in *Music*, denotes a kind of internal sense, by which we perceive and judge of harmony and musical sounds. In music we seem universally to acknowledge something like a sense distinct from the external one of hearing, and call it a *good ear;* and a similar distinction we should probably acknowledge in other affairs, if we had distinct names by which to denote these powers of perception. Thus a greater capacity of perceiving the beauties of painting, sculpture, and architecture, is called a *fine taste.*

EARING, in nautical language, is that part of the bolt rope which at the four corners of the sail is left open, in the shape of a ring. The two uppermost parts are put over the ends of the yard-arms, and so the sail is made fast to the yard; and into the lowermost earings the sheets and tacks are seized or bent at the clew.

EARL, a British title of nobility, next below a marquis, and above a viscount. The title is so ancient, that its origin cannot now be clearly traced out. It seems tolerably certain, however, that amongst the Saxons they were called *ealdormen*, elder men, a word of the same signification with *senior* or *senator* among the Romans; and also *schiremen*, because they had each of them the civil government of a civil division or shire. On the irruption of the Danes they changed their names to *eorels*, which, according to Camden, had the same signification in their language. In Latin they are called *comites*, a title first used in the empire, from being the king's attendants; *a societate nomen sumpserunt, reges enim tales sibi associant.* After the Norman conquest they were for some time called *counts*, from the French; but they did not long retain that name themselves, though their shires are thence denominated *counties* to this day. It is now become a mere title, the holders of which have nothing to do with the government of the county, that being now entirely devolved on the sheriff, the earl's deputy or *vicecomes.* In writs, commissions, and other formal instruments, the king, when he mentions any peer of the degree of an earl, usually styles him trusty and well-beloved cousin; an appellation as ancient as the reign of Henry IV., who being, either by his wife, his mother, or his sisters, actually related or allied to every earl in the kingdom, artfully and constantly acknowledged that connection in all his letters and other public acts; whence the usage descended to his successors, though the reason has long ago failed.

EARNEST (Arrhæ), money advanced in order to bind the parties to the performance of a verbal bargain. By the civil law, he who recedes from his bargain loses his earnest, and if the person who received the earnest give back, he must return the earnest double. But with us, the person who gives it is in strictness obliged to abide by his bargain; and in case he decline it, he is not discharged upon forfeiting his earnest, but may be sued for the whole money stipulated.

EARTH, amongst ancient philosophers, one of the four elements of which the whole system of nature was believed to be composed.

Earth, in *Astronomy* and *Geography*, one of the primary planets, being the terraqueous globe which we inhabit. (See the articles Figure of the Earth, and Geology.)

EARTHS, in *Chemistry*. These bodies will be found described in the article Chemistry, under the heads *Alkaline Bases* and *Earthy Bases.*

EASEL Pieces, among painters, such small pieces, whether portraits or landscapes, as are painted on the easel, or frame whereon the canvass is laid. They are thus denominated in order to distinguish them from larger pictures drawn on walls, ceilings, and the like.

EASING, in the sea language, signifies the slackening of a rope or the like. Thus, to ease the bow line, or sheet, is to let them go slacker; to ease the helm, is to let the ship go more large, more before the wind, or more larboard.

EASINGWOLD, a market-town in the north riding of the county of York, 208 miles from London and 11 from York. It is in the wapentake of Bulmer. It has a market on Friday, where much butter and bacon, cured in the neighbourhood, are disposed of for distant places. The population amounted in 1801 to 1467, in 1811 to 1576, in 1821 to 1912, and in 1831 to 2381.

EAST, one of the four cardinal points of the world, being that point of the horizon where the sun is seen to rise when in the equinoctial. The word *east* is Saxon. In Italy, and throughout the Mediterranean, the east wind is called the *levante;* in Greek, ανατολη and απηλιωτης, because it comes from the side of the rising sun, απ' ἡλιου, in Latin *Eurus.*

EASTBOURNE, a town on the coast of Sussex, in the hundred of that name, within the rape of Pavensey. It is 63 miles from London, and is one of those places which, from the prevalence of sea-bathing, has within the last fifty years been raised from a fishing village to be a large and populous town. It is situated in a chasm between two cliffs, through which runs a small stream. One of these, Beachy Head, is the loftiest headland on the English Channel. It consists of three distinct parts, each near half a mile from the other. The resident population amounted in 1801 to 1668, in 1811 to 1806, in 1821 to 2607, and in 1831 to 2726; but the visitors are said to be much more numerous during the bathing season.

EAST Island, a small island in the Eastern Seas, near the coast of Patawan. Long. 118. 36. E. Lat. 8. 40. N. Also a small island on the east coast of Borneo. Long. 109. 38. E. Lat. 2. 40. N. Likewise an island in the South Pacific Ocean, on the coast of New Zealand, near Cape East.

EASTER, a festival of the Christian church, observed in memory of our Saviour's resurrection. The Greeks call it *pasga*, the Latins *pascha*, from a Hebrew word signifying *passage*, applied to the Jewish feast of the passover. It is called *Easter* in English, from the goddess Eostre, who was worshipped by the Saxons with peculiar ceremonies in the month of April. The Asiatic churches kept their Easter upon the very same day on which the Jews observed their passover, and others on the first Sunday after the first full moon in the new year. This controversy was determined in the council of Nice, when it was ordained that Easter should be kept upon one and the same day, which should always be a Sunday, in all Christian churches in the world.

Easter Island, an island in the South Sea, lying in Long. 109. 46. W. Lat. 27. 5. N. See the article Polynesia.

EASTON, a post-town and burgh of Pennsylvania, and capital of the county of Northampton, United States. It is situated on the Delaware, at the junction of the Lehigh River and Canal, and also near the western end of the Morris Canal, which connects it with New York. It is regularly laid out, handsomely built, and possesses a considerable trade. In the vicinity of this place there are several valuable mills. The situation of the town is low, and it is surrounded by considerable eminences. Here there is a bridge across the Delaware, 570 feet in length. The population in 1820 amounted to 2370, and has since increased. It is distant 60 miles north of Philadelphia, and 73 west of New York.

EASTPORT, a post-town and sea-port of Maine, in the county of Washington, situated at the most eastern limit of the United States, on Morse Island, in Passamaquoddy Bay. It is a flourishing commercial place, and is very well situated for trade, having ample facilities for communication with the interior, by means of two rivers which flow into the bay. Its harbour is very capacious, and of safe entrance, and is considered as one of the best in the United States. About 1500 tons of shipping belong to it. The exports consist of lumber, and provisions of various kinds. The population in 1820 amounted to 1937. Long. 66. 56. W. Lat. 44. 54. N.

EAUZE, an ancient city of the department of Gers, in France, said to have been taken by the Saracens in 722. It is situated on the river Selise, was formerly called Elusa, and is the chief place in Aquitain. It now contains 3220 inhabitants. Long. 0. 3. W. Lat. 43. 56. N.

EAVES, in *Architecture*, the margin or edge of the roof of a house, being the lowest tiles, slates, or the like, which hang over the walls, in order to throw off water to a distance from the foundations.

Eaves-Droppers, are such persons as stand under the eaves or walls and windows of a house, by night or by day, to hearken after news, and carry it to others, and thereby cause strife and contention in the neighbourhood. They are called by the *Stat. of West.* i. c. 33, *evil members of the commonwealth.*

EBDOMARIUS, or Hebdomarius, in ecclesiastical writings, an officer formerly appointed weekly to superintend the performance of divine service in cathedrals, and prescribe the duties of each person attending in the choir, as to reading, singing, praying, and the like. For this purpose the hebdomary, at the beginning of his week, drew up in form a bill or writing of the respective persons, and their several offices, called *tabula*, and the persons there entered were styled *intabulati.*

EBDOME, Εβδομη, in *Antiquity*, a festival kept on the seventh of every lunar month, in honour of Apollo, to whom all seventh days were sacred, because one of them was his birth-day; and hence he was sometimes called *Ebdomagenes.*

EBERBACH, a bailiwick in the circle of the Neckar, in the duchy of Baden, in Germany, comprehending one city and nineteen villages, with 7890 inhabitants. The capital, of the same name, is situated on the Neckar, and has 2843 inhabitants.

EBERHARD, John Augustus, an eminent German theologian and philosopher, was born at Halberstadt, in Lower Saxony, on the 31st of August 1739. His father was the singing-master at the church of St Martin's in that town, and also teacher of the school of the same name; a man, it is said, of a lively disposition, and considerable literary attainments. Young Eberhard was educated partly at home and partly in the school above mentioned. In the seventh year of his age he repaired to the University of Halle, with the view of prosecuting his theological studies. Towards the end of the year 1759 he returned to his native town, and became tutor to the eldest son of the Baron Von der Horst, to whose family he attached himself for a number of years. In the year 1763 he was appointed con-rector of the school of St Martin's, and second preacher in the Hospital Church of the Holy Ghost; but he soon afterwards resigned these offices, and followed his patron to Berlin.

The advantages he enjoyed, in this family, of being introduced into the best company, tended to polish his manners, and to form, even at an early period, a style of writing which served as a model to many of his contemporaries. His residence at Berlin gave him an opportunity of extending his knowledge, and of cultivating the acquaintance of some of the most eminent literary characters in Germany. Amongst these were Nicholai and Mendelssohn, with whom he associated upon terms of intimate friendship.

In the year 1768 he accepted the situation of preacher or chaplain to the work-house at Berlin, along with that of preacher in the neighbouring fishing village of Stralow. The income from these livings was small; but his object was to continue at Berlin, and he had at the same time the promise of further preferment upon the first vacancy. He now applied, with renewed ardour, to the study of theology, philosophy, and history; and the first fruits of his talents and application soon appeared in his *New Apology of Socrates;* a work exhibiting such originality of thought and eloquence of style as at once established his character as a writer. This work was occasioned by an attack which was made on the sentiments contained in the fifteenth chapter of Marmontel's *Belisarius*, by one Peter Hofstede, a clergyman of Rotterdam, who, with a contemptible industry, raked up the vices of the most celebrated characters in the pagan world, and even went so far as to maintain that the most virtuous amongst the heathen were no fit objects of divine mercy. He seemed particularly desirous to blacken the character of Socrates; and from this circumstance Eberhard was induced to give to his work the title which we have mentioned above. The greater part of it is occupied with an investigation of some of those peculiar doctrines which have been admitted as dogmas of the Christian church, upon the authority of some of the early fathers; and an examination of those texts of Scripture upon which they are founded. The *Apology* itself, which constitutes but a small part of the book, is esteemed a masterpiece of clear, dignified, and persuasive eloquence. The whole work exhibits much reading and philosophical reflection; but the liberality of his reasoning gave great offence to many of the strictly orthodox divines of his time, and is believed to have obstructed his preferment in the church.

In the year 1774 he was appointed to the living of Charlottenburg; and he employed the leisure he had in this situation in publishing a second volume of his *Apology;* in which he not only endeavours to obviate some objections which were taken to the former part, but continues his inquiries into the doctrines of the Christian religion, religious toleration, and the proper rules for interpreting the Scriptures. Perceiving that his further promotion in the church would be attended with difficulty, he resolved, although reluctantly, to accept the situation of professor of philosophy at the University of Halle, which became vacant in 1778, by the death of G. F. Moier. But however excellent as a writer, and however just his ideas upon philosophical subjects, he does not appear to have been peculiarly qualified to excel as a teacher. He was highly esteemed, indeed, both by professors and students; but his lectures, although they attracted at first a considerable concourse, never acquired any degree of popularity. He continued, however, to lecture very regularly; and published several manuals for the use of his pupils.

On his arrival at Halle, the philosophical faculty presented him with a diploma as doctor in philosophy and master of arts. In 1786 he was admitted a member of the Berlin Academy of Sciences; and in 1805 the king of Prussia conferred upon him the honorary title of a privy councillor. In 1808 he obtained the degree of doctor in divinity, which was given him as a reward for his theological writings. He married in 1778, but had no children. He died on the 6th of January 1809, being then in the seventieth year of his age.

Eberhard's attainments in philosophy and literature were extensive and profound. He was master of the learned languages, spoke and wrote French with facility and correctness, and understood English, Italian, and Dutch. He had read a great deal, was thoroughly versed in the philosophical sciences, and possessed a just and discriminating taste for the fine arts. He was a great lover of music, and was himself a proficient in that science. His manners were mild and unassuming; and his amiable and cheerful disposition, no less than his talents and virtues, endeared him to a numerous circle of friends.

The following is a list of his works:

Neue Apologie des Socrates, &c. 2 vols. 8vo. The first volume was published in 1772, the second in 1778; both have been since republished.

Allgemeine Theorie des Denkens und Empfindens, &c. Berlin, 1776, 8vo. This essay obtained the prize assigned by the Royal Society of Berlin for that year. A new edition appeared in 1786.

Von dem Begriff der Philosophie und ihren Theilen, Berlin, 1778, 8vo. A short essay, in which he announced the plan of his lectures on being appointed to the professorship at Halle.

Lobschrift auf Herrn Johann Thunmann, Prof. der Weltweisheit und Beredsamkeit auf der Universität zu Halle. Halle, 1779, 8vo.

Amyntor, eine Geschichte in Briefen. Berlin, 1782, 8vo. This work was written with the view of counteracting the influence of those sceptical and Epicurean principles in religion and morals which were then so prevalent in France, and thence rapidly spreading amongst the higher ranks in Germany. It is composed with great elegance and perspicuity, and exhibits much philosophical reflection, and knowledge of the world. The story is simple, and seems to have been merely intended as a vehicle for the sentiments.

Ueber die Zeichen der Aufklärung einer nation, &c. Halle, 1783, 8vo. A lecture delivered at Halle, in presence of his Serene Highness the reigning Duke of Wurtemberg.

Theorie der Schönen Kunste und Wissenschaften, &c. Halle, 1783, 8vo. 3d ed. 1790.

Vermischte Schriften. Halle, 1784.

Neue vermischte Schriften. Ib. 1786.

Allgemeine Geschichte der Philosophie, &c. Halle, 1788, 8vo; 2d ed. with a continuation and chronological tables, 1796. Eberhard published also an abridgment of this work in 1794.

Versuch einer Allgemeinen-Deutschen Synonymik, &c. Halle and Leipsic, 1795–1802, 6 vols. 8vo. This is esteemed a classical work on the Synonymes of the German Language. An abridgment of it was published by the author in one large volume 8vo. Halle, 1802.

Handbuch der Aesthetik, &c. Halle, 1803–1805, 4 vols. 8vo.

Besides the works above mentioned, Eberhard contributed a number of small tracts and essays to various periodical and scientific publications, and translated several foreign works. He was also the editor of the *Philosophical Magazine*, Halle, 1788–1792, and of the *Philosophical Archives*, Halle, 1793–1795. These two periodical works, which are now little read, were instituted for the purpose of controverting the metaphysical principles of Kant, and of vindicating the doctrines of Leibnitz and Wolf.

Frederick Nicolai published a Memoir on the life and character of Eberhard, Berlin and Stettin, 1810, 8vo. See also K. H. Jördens, *Lexicon Deutscher Dichter und Prosaisten;* and *Biographie Universelle.*

EBERMANSTADT, a bailiwick of the circle of the Upper Maine, in the kingdom of Bavaria, extending over ninety-two square miles, containing one city, two market-towns, and thirty-three villages, with 9690 inhabitants. The chief place is the town of that name, situated on the river Wiesent, with 650 inhabitants.

EBERN, a bailiwick of the circle of the Lower Maine, in the kingdom of Bavaria, extending over seventy-one square miles. It contains one city, one market-town, and 11,400 inhabitants. It is watered by the river Baunach, has excellent pasture, and moderate corn land. The capital, of the same name, contains 207 houses, and 1100 inhabitants employed in making glass and porcelain wares.

EBERSBACH, a town of the circle of Lausatia, in the kingdom of Saxony. It contains 700 houses and 5400 inhabitants, who have more than 1500 looms at work making linen.

EBERSBERG, a bailiwick in the circle of the Isar, of the kingdom of Bavaria, extending over 240 square miles. It contains three market-towns, 148 villages, and 3436 houses, with 16,187 inhabitants. The chief town is of the same name, and contains 176 houses and 940 inhabitants.

EBERSDORF, a market-town of the principality of Reuss of the Branch. It contains the prince's castle, and 1270 inhabitants, of whom about 400 are industrious Hernhutters or Moravians. It is the capital of a bailiwick of the same name, which comprehends one other town and fourteen villages. There is a town of the same name in Austria, but very small, and known as the lodging of Bonaparte the night before the battle of Aspern.

EBESFALVA, a city of the Austrian kingdom of Hungary, in the province of Magyaren and circle of Kohelburg. It is well built, and contains an Arminian, a Greek, and a Calvinist church, with 4200 inhabitants, employed in manufactures and trade. Long. 13. 30. 16. E. Lat. 46. 11. 48. N.

EBHER, a town of Persia, in the province of Irak, situated on a river of the same name, in a fertile country. It contains 1000, or, as some say, 2500 houses, and has mosques, caravanserais, bazars, and other public edifices. It is thirty miles west of Casbin.

EBINGEN, a city of the kingdom of Bavaria, in the province of the Black Forest and circle of Bahlingen. It stands on the river Schmeica, and contains 4350 inhabitants, the most industrious manufacturers of woollen goods, hosiery, hats, and leather of any in that kingdom. Most of the goods made by them are disposed of at the fairs of Frankfort and of Zurzach. Long. 10. 58. E. Lat. 48. 13. 40. N.

EBION, the author of the heresy of the Ebionites, was a disciple of Cerinthus, and successor to that person. He improved upon the errors of his master, and added to them new absurdities of his own. He began his preaching in Judea; and he taught in Asia, and even at Rome. His tenets infected the isle of Cyprus. St John opposed both Cerinthus and Ebion in Asia; and it is thought that this apostle wrote his gospel in the year 97 in order to overthrow this heresy.

EBIONITES, ancient heretics, who appeared in the church in the first ages, and formed themselves into a sect in the second century, denying the divinity of Jesus Christ.

Origen conceives them to have been so called from the Hebrew word *ebion*, signifying *poor*, because, according to him, they were poor in sense, and wanted understanding. Eusebius, with a view to the same etymology, is of opinion they were so called from having poor thoughts of Jesus Christ, by taking him for a mere man. But it is more probable the Jews gave this appellation to the Christians in general out of contempt; because in the first ages there were few except poor people who embraced the Christian religion. This opinion Origen himself seems to incline to in his book against Celsus, where he says that they called those among the Jews who believed that Jesus was truly the expected Messiah, Ebionites. It might even be urged, with some probability, that the primitive Christians assumed the name themselves, in conformity with their profession; and it is certain that they valued themselves on being poor, in imitation of the apostles. Epiphanius, however, is of opinion that there had been a man named Ebion, the chief and founder of the sect of Ebionites, and contemporary with the Nazarenes and Cerinthians; and he gives a long account of the origin of the Ebionites, stating that they arose after the destruction of Jerusalem, when the first Christians, called Nazarenes, went out in order to live at Pella.

The Ebionites were little else than a branch of Nazarenes, only that they altered and corrupted in many things the purity of the faith as held by the first adherents of Christianity. For this reason Origen, in his answer to Celsus, distinguishes two kinds of Ebionites; one of whom believed that Jesus Christ was born of a virgin, and the other that he was born after the manner of other men. The first were orthodox in every thing, except that to the Christian doctrine they joined the ceremonies of the Jewish law, together with the traditions of the Pharisees. They differed from the Nazarenes, however, in several things, particularly as to the authority of the sacred writings; for the Nazarenes received all as Scripture that was contained in the Jewish canon, whereas the Ebionites rejected the prophets, holding the very names of David, Solomon, Isaiah, Jeremiah, and Ezekiel in abhorrence, and also the Epistles of St Paul, whom they treated with the utmost disrespect. They received nothing of the Old Testament except the Pentateuch; a circumstance which indicates that they were descended rather from the Samaritans than from the Jews. They agreed with the Nazarenes in using the Hebrew gospel of St Matthew, otherwise called the Gospel of the Twelve Apostles; but they had corrupted their copy in many places, and, particularly, had left out the genealogy of our Saviour, which was preserved entire in that of the Nazarenes, and even in those used by the Cerinthians.

Some, however, have made this gospel canonical, and of greater value than our present Greek gospel of St Matthew. The Nazarenes, whose sentiments as to the birth of our Saviour were the same with those of the Ebionites, built their error on this very genealogy.

Besides the Hebrew gospel of St Matthew, the Ebionites had adopted several other books, under the names of St James, St John, and the other apostles; they also made use of the travels of St Peter, which are supposed to have been written by St Clement, but altered them so that scarcely any truth was left in them; and in order the better to authorize their own practices, they even made that saint tell a number of falsehoods. (See St Epiphanius, who is very diffusive on the ancient heresy of the Ebionites, *Hær.* 30. But his account deserves little credit, as, by his own confession, he has confounded the other sects with the Ebionites, and has charged them with errors to which the first adherents of this sect were utter strangers.)

EBONY, a species of wood, exceedingly hard and heavy, susceptible of a very fine polish, and on that account used in mosaic and inlaid works, toys, and the like. There are different kinds of ebony, but the most usual amongst us are black, red, and green, and almost all of them the product of the island of Madagascar, where the natives call them indifferently *hazon mainthi*, or *black wood*. The island of Mauritius likewise furnishes part of the ebonies used in Europe. Authors and travellers give very different accounts of the tree which yields the black ebony. According to some of their descriptions, it would appear to be a sort of palm tree; but according to others, a cytisus. The most authentic of these is that of Falcourt, who resided many years in Madagascar as governor. He assures us that it grows very high and large, its bark being black, and its leaves resembling those of our myrtle, of a deep dusky green colour. Tavernier says that the islanders always take care to bury their trees when cut down, in order to make them blacker, and to prevent their splitting when wrought. Plumier mentions another black ebony tree, discovered by him at St Domingo, which he calls *spartium portulacæ foliis aculeatum ebeni materiæ*.

Pliny and Dioscorides state that the best ebony comes from Ethiopia, and the worst from India; but Theophrastus prefers that of India. Black ebony is much preferred to that of other colours. The best is a jet black, free of veins and rind, very massive, astringent, and of an acrid pungent taste. Its rind, infused in water, is said to purge pituita, and cure venereal disorders; and hence Matthiolus took guaiacum for a sort of ebony. It yields an agreeable perfume when laid on burning coals; when green it readily takes fire from the abundance of its fat. If rubbed against a stone it becomes brown. The Indians make statues to their gods and sceptres for their princes out of this wood. It was first brought to Rome by Pompey after he had subdued Mithridates. It is now much less used amongst us than anciently, since the discovery of so many ways of giving other hard woods a black colour.

As to the green ebony, besides Madagascar and the Mauritius, it grows likewise in the Antilles, and especially in the isle of Tobago. The tree which yields it is very bushy; its leaves are smooth, and of a fine green colour. Beneath its bark there is a white blea, about two inches thick; and all beneath this, to the very heart, is a deep green, approaching towards a black, though sometimes streaked with yellow veins. Its use is not confined to mosaic work; it is likewise employed in dyeing, as yielding a fine green tincture. As to red ebony, called also *grenadilla*, we know little more of it than the name.

EBRO, a river of Spain. It has its source in the province of Toro, about ten miles west of Reynosa, from out of the two springs of Fontibre, whence it runs south-east, divides Burgos and Soria from Alava and Navarre, passes through Aragon, becomes navigable near Logrono, and, after a course of 362 miles near Amposta, empties itself into the Gulf of Alfaques. Its tributary streams are the Tadorra, the Ega, the Queiles, the Alhama, the Xalon, the Gallega, the Guadalupe, and the Segre.

EBUDÆ, or HEBUDES, in *Ancient Geography*, islands off the west coast of Scotland, now called the *Western Isles*, also *Hebrides*.

ECALESIA, Εϰαλησια, in *Antiquity*, a festival held in honour of Jupiter, surnamed *Hecalus*, or *Hecalesius*, from *Hecale*, one of the boroughs in Attica.

ECASTOR, in *Antiquity*, an oath in which Castor was invoked. It was a custom for the men never to swear by Castor, nor the women by Pollux.

ECATÆA, Εϰαταια, in *Antiquity*, statues erected to the goddess Hecate, for whom the Athenians had a great veneration, believing that she was the overseer of their families, and that she protected their children.

ECATESIA, Εϰατησια, in *Antiquity*, an anniversary solemnity, observed by the Stratonicensians, in honour of Hecate. The Athenians likewise had a public entertainment or supper every new moon, in honour of the same goddess. The supper was provided at the charge of the more affluent; and it was no sooner brought to the accustomed place than the poor people carried all off, giving out that Hecate had devoured it. For the rest of the ceremonies observed on this occasion, see Potter, *Arch. Græc.* lib. ii. cap. 20.

ECATOMBÆON, Εϰατομϐαιων, in *Chronology*, the first month of the Athenian year. It consisted of thirty days, and began on the first new moon after the summer solstice, and consequently answered to the latter part of our June and beginning of July. The Bœotians called it *Hippodromus*, and the Macedonians *Lous*. The word is a derivation from the Greek ἡϰατομϐη, a *hecatomb*, because of the number of hecatombs sacrificed in it.

ECAVESSADE, in the manège, is a term used for a jerk of the cavesson.

ECBATANA, more properly written Agbatana, the chief city of Media, and the summer residence of its princes. Its foundation is ascribed by Herodotus to Dejoces, first king of Media, who reigned about 733 B. C.; but as this period of history is involved in much obscurity, we have some reason to doubt the correctness of his statement. The account of Diodorus, ii. 13, proves that it existed at a still earlier period, and belonged to that era in the Median history which preceded the reign of Semiramis. That princess, who is supposed to have lived about 1916 B. C., indulged her love of magnificence by the erection of a royal palace within its walls; and finding the city in great want of water, she constructed a splendid aqueduct, which furnished a plentiful supply of that first necessary of life. Pliny, vi. 14, would have us believe that Seleucus Nicator was the founder; but as this prince lived about 320 B. C. we cannot give credit to this statement, except he means that Seleucus became its second founder, after it had suffered from the calamities of war.

The citadel was remarkable for strength, and constructed in a very peculiar manner. Being situated upon a hill, it was surrounded by seven walls, in such a way that the bulwarks of the one wall rose high above those of the other, whilst each of them was distinguished by its own particular colour. The circumference of the outermost wall was equal to that of the city of Athens, or rather to 240 stadia, according to Diodorus; but this wonderful account ought to be received with some degree of hesitation.

Ecbatana was from the most ancient times the place of the royal residence, and seems in splendour and magnificence to have far exceeded all other cities. It was to it that Cyrus carried the captive Crœsus, 546 B. C. when he put an end to the Lydian empire; and in the later years of his life, when the infirmities of age made him more susceptible of the vicissitudes of the seasons, he used to retire for the summer months to its cool and delicious shades. (Xen. Cyrop. viii. 6.) Here Artaxerxes assembled his army to oppose the designs of his brother Cyrus (Diodorus xiv. 22); and when the fate of Persia was decided by the battle of Arbela, this was the spot chosen by Darius as the rallying point for his fugitive soldiers. (xvii. 64.) But no sooner did Alexander show his determination to attack it, than Darius ingloriously fled, and Ecbatana fell, with all its riches, into the hands of the Macedonian conqueror. (Arrian, 3, 19, 4.) The magnificence of its palace is particularly remarked by Polybius, who tells us that the wood was all of cedar or of cypress; the beams, the ceilings, and the pillars that supported the porticoes, were covered, some with plates of silver, and some with plates of gold. The tiles likewise were all of silver. It was of course plundered by the Macedonians; yet in the time of Antiochus, 209 B. C. he still found there pillars cased with gold, and a large quantity of silver tiles laid together in a heap. Amidst all the changes of empire in the East we find that Ecbatana continued to a very late period one of its principal cities. Vologeses held his court within its walls 64 A. D. (Tacit. *Ann.* xv. 31.)

The site of this ancient town seems unquestionably to have been near Hamadan in Al Djebal, though some are inclined to place it at Tebriz in Aderbidjon; and a late writer, Mr Williams, has even attempted to prove it to have been at Ispahan. This opinion he supports with great ability, but it is nothing else than a splendid paradox. The chief authorities adduced to prove its position are the following: It is situated at the foot of Mount Orontes, Polyb. x. 27; twelve stadia distant from it, Diodor. ii. 13; twelve long days' journey from the Caspian Gates, Arrian, iii. 20; 450 miles from Gaza, the capital of Atropatene, Plin. vi. 13; from Susa fifteen days' journey, Diodor. xvii. 110; and twenty from Persepolis, xix. 46.

The country round Hamadan at present abounds in gardens, vineyards, and pasturages; and though it is a gloomy abode during winter, on account of the cold, it is a delightful residence during the summer months. The tomb of Esther is still pointed out, and continues to be visited by Jewish pilgrims (Otter, *Voyage en Turquie*, vol. i. p. 182); and also the tomb of Avicenna. Abdool Kerim's *Travels from India to Mecca*, p. 97. See MOUNT ORONTES.

ECCHELLENSIS, ABRAHAM, a learned Maronite, whom the president Le Jai employed in the edition of his Polyglott Bible. Gabriel Sionita, his countryman, brought him to Paris in order to make him his fellow-labourer in publishing that Bible. But they quarrelled, upon which Gabriel complained to the parliament, and cruelly defamed his associate. This dispute made a great noise. The congregation *de Propaganda Fide* associated him in 1636 with those whom they had employed in making an Arabic translation of the Scriptures; they recalled him from Paris, and he laboured in that translation at Rome in the year 1652. Whilst he was professor of the oriental languages at Rome, he was selected by Duke Ferdinand II. to translate from Arabic into Latin the fifth, sixth, and seventh books of Apollonius's Conics; a task in which he was assisted by John Alphonso Borelli, who added commentaries to them. He died at Rome in 1644.

ECCLES, one of those large manufacturing towns which within a few years have risen from villages. It is 185 miles from London and four from Manchester, in the hundred of Salford, and county of Lancaster. The inhabitants are chiefly occupied in the several branches of the cotton manufacture; and amounted in 1801 to 6197, in 1811 to 12,300, in 1821 to 23,331, and in 1831 to 28,083.

ECCLESAL-BIERLOW, a large township of the parish of Sheffield, about three and a half miles from that town. The inhabitants are chiefly occupied in the various branches of the metal manufactures; and amounted in 1801 to 5362, in 1811 to 6569, in 1821 to 9113, and in 1831 to 14,279.

ECCLESFIELD, a large manufacturing parish of the west riding of Yorkshire, in the wapentake of Strafforth and Tickhill, 167 miles from London and five from Sheffield, with the trade of which place it is very much connected. The population amounted in 1801 to 5114, in 1811 to 5805, in 1821 to 7163, and in 1831 to 7911.

ECCLESHALL, a market-town of the county of Stafford, 148 miles from London. It is in the hundred of Pirehill, on the banks of the river Sow; is a well-built town, in a pleasant district; and was formerly the residence of the bishops of Lichfield. The chief part of the inhabitants are employed in manufactures. The market is held on Thursday. The population amounted in 1801 to 3487, in 1811 to 3901, in 1821 to 4227, and in 1831 to 4471.

ECCLESIASTES, a canonical book of the Old Testament, the design of which is to show the vanity of all sublunary things. It was composed by Solomon, who enumerates the several objects on which men place their happiness, and then shows the insufficiency of all worldly enjoyments. The Talmudists made King Hezekiah the author of this book; while Grotius ascribes it to Zorobabel, and others to Isaiah; but the generality of commentators believe it to be the product of Solomon's repentance, after having experienced all the follies and pleasures of life.

ECCLESIASTICAL, an appellation given to whatever belongs to the church. Thus we say ecclesiastical polity, jurisdiction, history, and so forth.

ECCLESIASTICUS, an apocryphal book, generally bound up with the Scriptures, and so called from its being read in the church, *ecclesia*, as a book of piety and instruction, but not of infallible authority. The author of this book was a Jew, called Jesus the son of Sirach. The Greeks call it the Wisdom of the Son of Sirach.

ECCLOO, a city in the province of West Flanders, which contains 6269 inhabitants. It is the capital of the circle of the same name, comprehending three cantons, with a population of 42,484 persons.

ECCOPROTICS, in *Medicine*, laxative or loosening remedies, which purge gently, by softening the humours and excrements, and fitting them for expulsion. The word is composed of the Greek particle εκ, and κοπρος, *fæces*.

ECDALA, or AKDALA, an ancient town and fortress of Bengal, in the district of Dacca, which is frequently mentioned in the histories of Bengal, but of which there are now scarcely any remains. In the year 1353 Ilyas Hajy, the second independent king of Bengal, took refuge here, and defended the place until the setting in of the rains, when the siege was raised. Long. 96. 45. E. Lat. 24. 4. N.

ECDICI, Εκδικοι, amongst the ancients, patrons of cities, who defended their rights, and took care of the public money. Their office resembled that of the modern syndics.

ECHALLANS, a bailiwick in the canton of Vaud, in Switzerland, containing 6954 inhabitants, whose capital is of the same name, and situated on the river Talent, containing 850 inhabitants.

ECHAPE, in the manège, a horse begotten between a stallion and a mare of different breeds and countries.

ECHAPER, in the manège, a gallicism used in the academies, implying to give a horse head, or to put him to full speed.

ECHINADES, a group of islands off the coast of Acarnania, at the mouth of the river Achelous. They are mentioned by Homer as having sent a detachment of troops to Troy under Meges. The chief island seems to have been Dulichium, which some of the ancients considered as only another name for Cephallenia; but Strabo strenuously maintained that it was the Dolicha of his period, at the mouth of the Achelous. It is curious that Herodotus (xi. 10), tells us that more than half of these islands had been joined in his time to the mainland by the depositions of the river, and Thucydides (xi. 102), enters into a learned disquisition to prove that they must all ere long be united to the shore. This observation of Thucydides had attracted the attention of the inquisitive Pausanias; and as he found that the prediction had not been verified, he was only able to account for it by supposing that the lands had ceased to be cultivated on its banks, and that thus it was no longer supplied with the same quantity of sediment as before. Strabo states that they were rugged and barren. "At present the Echinades belong to the inhabitants of Ithaca, and produce corn, oil, and a scanty pasture for sheep and goats. The name of the group is *Curzolari*." Dodwell's *Classical Tour*, v. p. 109. Gell states that several of these islands, now hills in the plain, appear to have ruins. *Itiner. of Greece*, p. 298.

ECHINATE, or ECHINATED, an appellation given to whatever is prickly, or resembling the hedgehog.

ECHINITES, the name by which authors call the fossil centronia, frequently found in chalk pits.

ECHINODERMATA, the first class of the fourth great division of the animal kingdom (see vol. iii. p. 179 of this work), commonly called Zoophytes, or radiated animals; it includes, among numerous other species, the star-fish, sea urchins, &c. We shall describe the animals of this class under the term ZOOPHYTES, to which the reader is referred.

ECHINUS. See ZOOPHYTES.

ECHO, a sound reflected or reverberated from a solid concave body, and so repeated to the ear. The word is formed from the Greek ηχος, *sound*, which comes from the verb ηχεω, *sono*.

The ancients being wholly unacquainted with the true cause of the echo, ascribed it to several which are sufficiently whimsical. But the moderns, who know sound to consist in a certain tremor or vibration in the sonorous body, communicated to the contiguous air, and by that means to the ear, give a more consistent account of echo. For a tremulous body, striking on another solid body, may evidently be repelled without destroying or diminishing its tremor; and consequently a sound may be redoubled by the resilition of the tremulous body, or air. But a simple reflection of the sonorous air is not enough to explain the echo; for then every plain surface of a solid hard body, as being fit to reflect a voice or sound, would redouble it, which we find does not hold. In order to produce an echo, therefore, it should seem that a kind of concameration or vaulting is necessary, in order to collect, and by collecting to heighten and increase, and afterwards reflect, the sound, as we find is the case in reflecting the rays of light, where a concave mirror is required. In effect, as often as a sound strikes perpendicularly on a wall, behind which is any thing of a vault or arch, or even another parallel wall, so often will it be reverberated in the same line, or other adjacent ones. For an echo to be heard, therefore, it is necessary that the ear should be in the line of reflection; for the person who made the sound to hear its echo, it is necessary that he should be perpendicular to the place which reflects it; and for a manifold or tautological echo, it is necessary that there should be a number of walls, and vaults or cavities, either placed behind or fronting each other. A single arch or concavity can scarcely ever stop and reflect all the sound; but if there be a convenient disposition behind it, part of the sound propagated thither, being collected and reflected as before, will return another echo; or if there be another concavity, opposed at a due distance to the former, the sound reflected from the one upon the other will be tossed back again by the latter.

Echoes may be produced in circumstances wholly different. For, first, a *plane* obstacle reflects back the sound in its due tone and loudness, allowance being made for the proportionable decrease of the sound, according to its distance; secondly, a *convex* obstacle reflects the sound somewhat smaller and somewhat quicker, though weaker, than otherwise it would be; and, thirdly, a *concave* obstacle echoes back the sound larger, slower, and also inverted, but never according to the order of words. Nor does it seem possible to contrive any single echo that shall invert the sound, and repeat backwards; because, in such a case, the word last spoken, that is, which last occurs to the obstacle, must be repelled first, which cannot be. For where in the mean time should the first words hang and be concealed; or how, after such a pause, could they be revived and animated again into motion? From the determinate concavity or arching of the reflecting bodies, it may happen that some of them shall only echo back one determinate note, and only from one place. Fourthly, the echoing body being removed farther off, it reflects more of the sound than when nearer, which is the reason why some echoes repeat but one syllable, some one word, and some many. Fifthly, echoing bodies may be so contrived and placed, that by reflecting the sound from one to the other, either directly and mutually, or obliquely and by succession, out of one sound, a multiple echo or many echoes shall arise. Add to this, that a multiple echo may be made, by so placing the echoing bodies at unequal distances, that they may reflect all one way, and not one on the other. By this means a manifold successive sound will be heard, one clap of the hands like many, one *ha* continued like laughter, one single word like many of the same tone and accent, and one viol like many of the same kind imitating each other. Lastly, echoing bodies may be so arranged that from any one given sound they shall produce many echoes different both as to tone and intention. By this means a musical room may be so contrived that one instrument playing therein shall not only seem as many of the same sort and size, but even as a concert of different ones; which is effected by placing certain echoing bodies so that any note placed shall be returned by them in thirds, fifths, and eighths.

Echo is also used for the place where the repetition of the sound is produced or heard.

Echoes are distinguished into different kinds. *Single echoes* are those which return the voice but once. Of these some are *tonical*, which only return a voice when modulated into some particular musical tone; and others, *polysyllabical*, which return many syllables, words, and sentences. *Multiple* or *tautological* echoes are those which return syllables and words the same oftentimes repeated.

In echoes, the place where the speaker stands is called the *centrum phonicum*, and the object or place that returns the voice the *centrum phonocampticum*.

At the sepulchre of Metella, wife of Crassus, there was an echo, which repeated what was said five times. Authors mention a tower at Cyzicus, where the echo repeated seven times. One of the finest echoes we read of is that mentioned by Barthius, in his notes on the *Thebais* of Statius (lib. vi. 30), which repeated the words uttered seventeen times; it was situated on the banks of the Naha, between Coblentz and Bingen. Barthius assures us that he had proved what he writes, and had counted seventeen repetitions.

Echo, in *Architecture*, a term applied to certain kinds of vaults and arches, most commonly of the elliptic and parabolic figures, used to redouble sounds, and produce artificial echoes.

Echo, in *Poetry*, a kind of composition in which the last words or syllables of each verse contain some meaning, which, being repeated apart, answers to some question or other matter contained in the verse. Thus, in the line of Virgil:

Crudelis mater magis, an puer improbus ille?
Improbus ille puer, crudelis tu quoque mater.

Echo, in fabulous history, a daughter of the Air and Tellus, who chiefly resided in the vicinity of the Cephisus. She was once an attendant of Juno's, and became the confidant of Jupiter's amours. Her loquacity, however, displeased Jupiter, and she was deprived of the power of speech by Juno, and only permitted to answer to the questions which were put to her. Pan had formerly been one of her admirers, but he never enjoyed her favours. Echo, after she had been punished by Juno, fell in love with Narcissus; but being despised by him, pined away, having nothing left but her disembodied voice.

ECHOMETER, among musicians, a kind of scale or rule, with several lines on it, serving to measure the duration and length of sounds, and to determine their intervals and ratios.

ECIJA, a city of Spain, in that division of Andalusia denominated the kingdom of Seville. It is situated on the right bank of the river Xenil, which is here crossed by a neat bridge of modern erection. The surrounding country suffers much from a scarcity of water; but when the summer happens to be rainy, it is abundantly productive in grain of every kind, and in wine, and feeds considerable herds of cattle. It was a considerable city when the Romans ruled the peninsula, and was then called Astigi. Many inscriptions of ancient date are found in the city and its vicinity. It contains six churches, sixteen monasteries, fifteen hospitals, 6000 houses, and 28,176 inhabitants. There are some tanneries here, and a trade in leather is carried on. Cotton is grown in the surrounding country. It is thirty miles from Cordoba. Long. 4. 34. 19. W. Lat. 37. 31. 51. N.

ECKIUS, or Echius, John, an eminent and learned controversialist, professor in the university at Ingolstadt, and remarkable for the opposition he gave to Luther, Melancthon, Carlostadius, and other leading Protestants in Germany, was born in Suabia in 1486. He wrote many polemical tracts; and amongst the rest a *Manual of Controversies*, printed in 1535, in which he discourses upon most of the heads contested between the Protestants and Roman Catholics. He also wrote a Commentary on Seligenstadt, 1536, *Homilies*, &c.; and died in 1543.

ECLECTICS (*eclectici*), a name given to some ancient philosophers, who, without attaching themselves to any particular sect, took whatever they judged good and solid from each; and hence their denomination. Laertius observes that they were also, for the same reason, denominated *analogetici*; but that they call themselves *philalethes*, or lovers of truth. The chief or founder of the eclectics was Potamon of Alexandria, who lived under Augustus and Tiberius, and who, weary of doubting of all things with the Sceptics and Pyrrhonists, formed the eclectic sect, called by Vossius the eclective.

Towards the close of the second century, a sect arose in the Christian church under the denomination of Eclectics, or modern Platonists, professing to make truth the only object of their inquiry, and to be ready to adopt from all the different systems and sects such tenets as they thought agreeable to it. However, they preferred Plato to the other philosophers, and looked upon his opinions concerning God, the human soul, and things invisible, as conformable to the spirit and genius of the Christian doctrine. One of the principal patrons of this system was Ammonius Saccas, who laid the foundation of that sect afterwards distinguished by the name of the New Platonists in the Alexandrian school.

Eclectics were also a certain sect of physicians among the ancients, of whom Archigenes, who lived under Trajan, was the chief, and selected from the opinions of all the other sects those which appeared to be best and most rational. Hence they are called *eclectics*, and their prescriptions *medicina eclectica*.

ECLIPSE, in *Astronomy*, the deprivation of the light of the sun, or of some heavenly body, by the interposition of another heavenly body between us and that body. See ASTRONOMY.

ECLIPSE ISLANDS, a cluster of small rocky barren islands in the South Pacific Ocean, near the south-west coast of New Holland.

ECLIPTIC, in *Astronomy*, a great circle of the sphere, supposed to be drawn through the middle of the zodiac, making an angle with the equinoctial of about 23° 30′, which is the sun's greatest declination; or, more strictly speaking, it is that path or way among the fixed stars, which the earth appears to describe to an eye placed in the sun. (See ASTRONOMY.) Some call it *via solis*, or the way of the sun, because the sun in his apparent annual motion never deviates from it, as all the other planets do more or less.

ECLIPTIC, in *Geography*, a great circle on the terrestrial globe, not only answering to, but falling within, the plane of the celestial ecliptic. See GEOGRAPHY.

ECLODE, a town of Hindustan, in the province of Malwah, belonging to the predatory chieftain Meer Khan. Long. 77. 55. E. Lat. 24. 5. N.

ECLOGUE, in *Poetry*, a kind of pastoral composition, in which shepherds are introduced conversing together. The word is formed from the Greek *εκλογη choice;* so that, according to the etymology, eclogue should be a select or choice piece; but custom has assigned to it a further signification, namely, a little elegant composition in a simple, natural style and manner.

Idyllion and eclogue, in their primary sense, are the same. Thus the *idyllia, ειδυλλια*, of Theocritus, are pieces written perfectly in the same vein with the *eclogæ* of Virgil. But custom has made a difference between them, and appropriated the name of *eclogue* to pieces in which shepherds are introduced speaking; and *idyllion* to those written, like the eclogue, in a simple, natural style, but without any pastoral interlocutors.

Of the Idyl, as the word is generally written, Germany in particular, amongst modern nations, has produced some highly finished specimens. England can boast of comparatively few eclogues so called. Those of Collins are esteemed the best.

ECONOMISTS.

IT is not generally known how much the science of politics, that master science, the late offspring of the improved reason of modern times, is indebted to the philosophers who are known to the world by the title of economists. They were, it is true, preceded in this country by Hobbes and by Locke, and in France by Montesquieu; but in analysing the frame of civil society, they added considerable lights to those which had been communicated by their predecessors; and they attempted to point out the mode of combining the various springs of social action in a more liberal and beneficent system than had yet been recommended to the world.

It is worthy of remark, that the merits of this sect, in the secondary department of *political economy*, have so much obscured their important speculations on the great questions respecting the best possible order capable of being given to society, that they are, in this country at least, wholly unknown, except in the character of political economists; though their political economy formed only a small and subordinate branch of their entire system; and, what is indeed extraordinary, we know not a book in the English language in which an account of that system is to be found.

This article is intended to contain, 1*st*, the history of the sect; 2*dly*, an account of their system; and, 3*dly*, some observations, pointing out the principal errors into which they have fallen.

I. M. de Gournay appears to have been the first man in France who had formed any systematic notions on the real principles of trade. It is true, indeed, that Fenelon had recommended, on the direct suggestion of good sense, detached from theory, the practice of freedom of trade. The Marquis d'Argenson was celebrated for the sound and important maxim, *Pas trop gouverner;* and the memorable advice of the merchants to the meddling Colbert was well known, *Laissez-nous faire.* Another of the more peculiar doctrines of the economists was expressed in the famous maxim of the great Duc de Sully, *Que le labourage et le pâturage sont les mammelles de l'état;* and Montesquieu had brightly but superficially run over several of the questions relative to trade.

For such lights as M. de Gournay did not derive from his own reflections, he seems to have been chiefly indebted to the writers of England; but there appears some reason to conclude that the best of these had not fallen in his way. We do not perceive, for example, any sign of acquaintance with the writings of Locke.

Jean-Claude-Maria Vincent, Seigneur de Gournay, was an extraordinary man for the age and country in which he was produced. He was born at St Malo, in the month of May 1712, the son of Claude Vincent, one of the most considerable merchants of the place. Destined to commerce by his parents, he was sent to Cadiz when scarcely seventeen years of age. His vigilant attention to business did not hinder him from finding time, well husbanded and diligently applied, not only for storing his mind with general knowledge, but for unravelling the combinations of commerce, and ascertaining its elementary principles. After he had raised himself to great eminence as a merchant, and to a high reputation for knowledge of the principles of commerce, the ministers of France conceived the design of turning his knowledge to advantage in the office of intendant of commerce, as they call it, to which he was raised in 1751.

No sooner was M. de Gournay invested with his office, than he began to wage war with the established system of regulations and restrictions, which the experience of twenty years of mercantile practice the most varied and the most extensive, discussions with the most intelligent merchants of Holland and of England, the perusal of the best writers on the subject, and the impartial application of his own philosophical thoughts, had all conspired to make him regard as a source, not of national advantage, but of continual vexation and hardship to individuals, and of poverty to the state. "He was astonished," says M. Turgot, "to find that a citizen could neither make nor sell a commodity, without having purchased a privilege, by getting himself made, at a great expense, a member of some corporation; that if he made a piece of cloth, for example, of any quantity and quality different from those commanded in certain regulations, instead of being allowed to sell it to those purchasers whom such quantity and quality suited the best, he should be condemned to see it cut in pieces, and to pay a fine heavy enough to reduce a whole family to beggary. He could not conceive how, in a country where the succession to titles, to estates, and even to the crown itself, rested upon custom, and where the application of even the punishment of death was rarely guided by any written definitions, the government should have thought proper to fix by written laws the length and breadth of each piece of cloth, and the number of threads which it ought to contain. He was not less astonished to see the government take in hand to regulate the supply of commodities; proscribe one sort of industry in order to make another flourish; shackle with peculiar restrictions the sale of the most necessary articles of subsistence; prohibit the storing of commodities, of which the quantity produced varies greatly from year to year, while the quantity required for consumption is pretty nearly the same; restrain the export and import of a commodity subject to the greatest fluctuation of price; and dream of insuring the plentiful supply of corn by rendering the condition of the labourer more uncertain and more wretched than that of any other part of the community." (*Œuvres* de M. Turgot, iii. 333.)

It may easily be imagined that M. de Gournay would find himself encountered by opposition the moment he endeavoured to introduce his beneficial views into practice. The grand instruments of this opposition were certain words and phrases, which have been used to screen misrule in every country in which the voice of reform has begun to be raised. "M. de Gournay," says Turgot, "was opposed, under the names of an 'innovator' and a 'theorist,' for endeavouring to develop the principles which experience had taught him, and which he found universally recognised by the most enlightened merchants of every part of the world among whom he had lived. The principles marked out for reprobation, under the title of the 'new system,' appeared to him to be exactly the principles of plain good sense. The whole of this system was founded upon the certain maxim, that, in general, each man is a better judge of his own interest, than another man to whom it is a matter of indifference. From this M. de Gournay concluded, that, when the interest of individuals is precisely the same with the general interest, the best thing to be done is, to leave every man at liberty to do what he likes. Now he held it as impossible, that in commerce, fairly left to itself, the interest of the individual should not coincide with the interest of the community." The proof which M. Turgot gives of the fundamental proposition, that the interest of the individual and of the community in a free commerce are the same, we need not repeat; because it can neither be rendered more clear nor more cogent than it is already in works with which every person is familiar, who is at all conversant with political science.

"From this principle M. de Gournay concluded, that the sole duties of government with regard to commerce are: 1. To render to all the branches of industry that precious liberty, of which the prejudices of barbarous times, the proneness of governments to lend themselves to the gratification of individual interests, and the pursuit of a mistaken good, have conspired to deprive them: 2. To facilitate the exercise of industry and ingenuity to every member of the community, exciting thereby the greatest competition among sellers, and ensuring the greatest perfection and cheapness of the commodities sold: 3. To admit the greatest competition among buyers, by opening to the seller every possible market; the sole means of encouraging reproduction, which hence derives its only reward: 4. To remove every obstacle by which the progress of industry is retarded, by depriving it of its natural reward."

It is to M. de Gournay, therefore, that Turgot ascribes the origin of political economy in France. "It is to the ardour," says he, "with which M. de Gournay endeavoured to direct to the study of commerce and of political economy, all the talent which he was able to discover, and to the facility with which he communicated the lights which he himself had acquired, that we ought to ascribe the happy fermentation which for some years has been excited on these important subjects; a fermentation which arose two or three years after M. de Gournay was intendant of commerce, and has since that time procured us several works calculated to wipe off from our nation that reproach of frivolity, which, by its indifference for the more useful studies, it had but too justly incurred."

Francis Quesnay was born in the village of Ecqueville in the year 1694. According to M. Dupont de Nemours, the editor and commentator of the works of Turgot, and a zealous economist, he was the son of a small proprietor, who cultivated his own little property; and he was eminently indebted to his mother for the fashion of his mind. Though he was educated as a physician, and rose to such eminence in his profession as to be first physician to the king, the early occupation of his mind on the business of agriculture had given the current of his thoughts a permanent direction; and when he was summoned to reflect on the sources of wealth, by the discussions probably to which the speculations of M. de Gournay had given birth, agriculture was the object on which his attention was more particularly fixed. He produced several works on different points of the science and practice of medicine; and it was only at a late period of life that his works on political economy appeared. His chief production on this subject, *Physiocratie, ou du Gouvernement le plus avantageux au genre humain*, was first published in 1768. Not only had the speculations which he broached, and which he propagated with much fervour and diligence, considerable success in the world, but he had the fortune to gain a considerable number of proselytes, who exerted themselves with an ardour for the diffusion of his doctrine, and with a devotion to the opinions of their master, which more resembled the enthusiasm of the votaries of a new religion, or that of the followers of some of the ancient philosophers, than the indifference with which new speculations in philosophy have on all other occasions been received in modern Europe; and which gave to the economists more of the character of a sect or a school, than has appeared to belong to those who have in recent times concurred in any other system of philosophical opinion.

There was, in truth, in the system of M. Quesnay and the other economists, many things well calculated to attract attention and excite enthusiasm. From a few simple principles, they deduced, as they imagined, by a chain of very close and imposing arguments, a system of changes which would easily be introduced, without the smallest interruption to the tranquillity and happiness of the existing generation, calculated to remove from society all the deformities by which it was overspread, and to communicate to the mass of human beings a fulness of happiness hitherto altogether unknown. At this point, therefore, we may close the historical part of this article; for the success of the great work of Dr Adam Smith, in a short time, superseded the *political economy* of the sect; and after the political economy was discredited, the rest of their doctrines met with little regard. The memory of them, however, is well worthy of being preserved; and this task we shall now, in as few words as possible, endeavour to perform.

II. The economists proceeded upon no Utopian plan, which supposes society to be composed of beings different from those with whom we are already acquainted. They took man as he is, a being having wants, and governed by the desire of avoiding pain and obtaining pleasure.

Man must have subsistence. Upon this ground they first took their stand. This being allowed, it followed, of course, that whatever was the best means of obtaining subsistence, would command the operations of men as soon as ever it was sufficiently known.

Of these means, the first and fundamental is the establishment of property. This they proved by convincing arguments. We cannot exist without consuming. The nature of man leads to a rapid multiplication of human beings, and the earth yields a spontaneous nourishment for only a few. To make food keep pace with population, labour must be employed upon the ground. Men would be born for no other purpose than that of destroying one another, if there were not means of increasing the quantity of food in proportion to those that were born. Labour, then, is one of the physical necessities of nature. But if labour be necessary, so is property, because, without property, there can be no labour.

The proof of this proposition is short and irresistible. Nobody would labour under an assurance that he would derive no advantage from his labour. Nobody would labour without a certain probability that he should enjoy the fruits of his labour. Now, this is property. The only question, then, which remains is, what is the degree of assurance with respect to the fruits of a man's labour; in other words, what are the laws of property which tend most to secure the benefits which human beings derive from their labour? This, said the economists, is the object and the end of our researches.

They proceeded in their inquiry by the following steps. As a means to this labour, on which every thing depends, a man must be free to use his natural faculties of labour —his muscular powers. This freedom they called *the property of his person.* As another means to the same end, he must be free to use exclusively, and to preserve, what he acquires by his labour. This they call his *moveable property.*

Here we see the origin of that to which men have assigned the names of *rights* and *duties.* The exclusive powers assigned to the man over his person, and over the fruits of his labour, are called his *rights.* To allow these exclusive powers, by abstaining from every act which would impair them, is called the *duties* of all other men. Here we see, also, that *rights* and *duties* are reciprocal; that they imply one another, that they are created together, and that the one cannot exist without the other. Destroy the *rights* of property in the man, you destroy, by the same act, the *duties* of other men to exclude themselves from what was called his property. Destroy, in the same manner, the *duties* of other men to exclude themselves from what was called his property, and you destroy, at the same time, his *right* to that exclusion. *Rights* and *duties* are, in fact, but different names given to the same thing, according as it is regarded under one or another of two points of view.

Another important concatenation is here also to be seen. *Rights* are advantages; things to be enjoyed. *Duties* are burthens, abstracted from things to be enjoyed. Why should men accept these burthens, submit to these duties? Why, but because they find their advantage in doing so. It is plain how they find their advantage in doing so, and there is, there can be, no other reason. Men submit to the *duties* of respecting other men's *rights,* that they may have *rights* themselves. It is good for them to have *rights;* there can be no rights without *duties.* It is better to have the *rights* submitting to the *duties,* than, by renouncing the *duties,* to have no *rights.* The *duties* are then the price which is paid for the *rights.* The *duties* which one man yields to other men, are the price which he pays for having *rights* of his own. *Duties,* then, are in themselves *evils;* and they never ought to exist, except when they are compensated by a greater good. Nobody ought to be subjected to a burthen, which is not, either to himself, or to the community in which he has clubbed his private interests, attended with a good sufficiently great to overbalance the evil which he is made to endure. *Utility,* then, is the exclusive foundation of *duty.*

Having laid this foundation, the economists proceed.

On the necessity of subsistence rests the necessity of property, and on the necessity of property rests the necessity of a certain inequality in the conditions of men. This inequality exists, because a good is obtained through it, which can in no other way be obtained; and that good the parent of every thing else to which the name of good is applied. "Those who complain of it," says Mercier de la Riviere, one of the chief expositors of the doctrines of the sect, "see not that it is a link in the chain by which the human species must drag from the abyss of non-production every thing which they enjoy. As soon as I have acquired the *exclusive* property of a thing, another man cannot have the property of it at the same time. The law of property is the same for all men; each man, however, acquires in proportion to his faculties of acquiring: but the measure of these is different in different men. And besides this fundamental law, there is, in the whirlpool of accidents, a continual succession of combinations, some more, some less fortunate, which increase the causes of that inequality of acquisition, without which the motives to acquisition cannot exist......................I admit, however," he in conclusion adds, "that in any given community, these differences in the possessions of different men may become the source of great disorders, and which augment again these same differences beyond their natural and necessary degree. But what follows from this? That men ought to establish an equality of conditions? Certainly not; for to that end, it would be necessary to destroy all property, and, by consequence, all society: it only follows that they should correct those disorders which make that which is an instrument of good become an instrument of evil; which alters in such a manner the distribution of things, that *force* places all the rights on one side and all the duties on the other."

We have seen that the necessity of labour to procure the means of life and the means of enjoyment, produced a necessity of *property personal* and *property moveable,* as the two sorts were named by the economists. The necessity of raising food, as well as the first material of most of the other articles of human enjoyment, by labour upon the *land,* produces a like necessity of creating a *property in the soil.* The proof of this proposition is not less short and convincing than that which regards the other species of property. To make the land yield a produce useful to man, it must be cleared of many incumbrances, and prepared with much labour and expense. No adequate return can be obtained for this labour to the man who would bestow it, without a perpetuity of possession. It is essential for the well-being of the species that the labour should be yielded, and in the greatest degree of perfection. It cannot be yielded perhaps at all, certainly in no tolerable degree of perfection, without that exclusive possession which constitutes property. Property in land is, therefore, essential to the well-being of the human species.

We see in this manner what are the *rights* and what are the *duties* which the supply of the first wants of human nature renders it necessary to constitute; but as all mankind are not disposed to respect *rights* and *duties,* it is necessary, in order to obtain the advantages which they are destined to produce, that measures should be taken to protect them.

The measures taken to protect them are generally comprehended under one name, that is, *government*. The protection of the rights, or, which means the same thing, the insuring of the duties, is the *end*, the government is the *means;* and the question is, what combination of means is best adapted to the purpose?

This assuredly is the most important question to which the human faculties can be directed; and the economists have never yet received the credit which is their due, for the ability and success with which they laboured to resolve it. No speculations can be conceived of more importance than those in which they engaged, nor has it yet become easy to throw upon them a greater portion of light.

The grand classes of means by the skilful combination of which they conceived that the end might be obtained, were either more direct or more indirect. The more indirect were liberty and evidence; the more direct were laws exactly adapted to the end, magistrates exactly adapted to the execution of these laws, and a supreme, or, as they called it, "*tutelary power*." We shall endeavour to communicate their leading ideas on each of these particulars.

1. *Liberty*. We have seen that the end which is aimed at through property, as a means, is the greatest possible abundance of the things adapted for human enjoyment, and that property is a means altogether indispensable for that end. It is now to be proved that liberty is absolutely necessary to enable property to answer the purpose of a means to that end, and that, without liberty, the existence of property is deprived of almost all its advantages. In fact, the right which a man has not the liberty to enjoy is not a right. The right of property in a man's person, in his moveables, in his land, is the right of enjoying; but the *right* of enjoying and the *liberty* of enjoying are the same thing. Liberty, therefore, cannot be hurt without damaging the right of property, and the right of property cannot be hurt without damaging liberty. "It is," says Mercier de la Rivière, "so inseparably connected with the right of property, that it is confounded with it, and that the one cannot exist without the other. Deprive a man," he cries, "of all the rights of property, and I defy you to find in him a vestige of liberty. On the other hand, suppose him deprived of every portion of liberty, and I defy you to show that he truly retains every right of property."

It is now pretty clear that liberty is necessary to produce that abundance of production which is the end aimed at by the constitution of all *rights* and *duties*. Man is excited to labour only in proportion as he is stimulated by the desire of enjoying; but the desire of enjoying can only be a motive of action in so far as it is not disjoined from the liberty of enjoying. You cannot have productions in abundance, without the greatest possible inducement to labour; you cannot have the greatest possible inducement to labour, without the greatest possible liberty of enjoyment. The chain of evidence is therefore complete.

"Let us not," say the economists, "seek in men beings which are not men. Nature has destined them to know only two springs of action, or moving powers; the appetite of pleasure and the aversion to pain. It is in the purpose of nature, therefore, that they should not be deprived of the liberty of enjoying, since, without that liberty, the first of those two powers would lose the whole of its force. *Desire of enjoying, liberty of enjoying;* these are the soul of the social movements, these are the fruitful seed of abundance, because that precious combination is the principle of all the efforts made by human beings to procure it."

2. *Evidence*. Property, and by consequence liberty and security of enjoying, being proved to constitute the essence of what they called the natural and essential order of society, it was seen to be in reality a chain of *physical* consequences, involving nothing arbitrary, nothing changeable; evident, on the other hand, simple, and resting on no other ground than that of being the most advantageous possible to the whole body of the community, and to every one of its members.

"The best possible order of society, however," they observed, "cannot be established where it is not sufficiently known; but for that very reason, that it is the best order, the establishment of it, as soon as it is known, must become the common ambition of men; it must then introduce itself by *necessity*, and, once established, it must by *necessity* continue for ever." These were bold promises, but the proof was correspondent. "The best possible order of society must introduce itself as soon as known, and preserve itself for ever as soon as introduced, because the appetite of pleasure, and the aversion to pain, the only moving powers within us, lead naturally and constantly toward the greatest possible augmentation of enjoyments; and the desire of enjoying implies by necessity that of the means by which enjoyment is procured. It is, then," said the economists, "impossible that men should know their best possible condition without a consequent union of all wills and all power to procure and to preserve it. Imagine not," they cried, "that for the establishment of this essential order it is necessary to change the nature of men, and divest them of their passions; their passions, on the other hand, become auxiliaries in this establishment, and, for the most complete success, it is only necessary to place them in a condition to see with *evidence* that it is in this order alone they can find the greatest possible sum of enjoyments and of happiness."

These philosophers made some admirable observations upon the nature of evidence, and the important purposes to which it is subservient. They made a distinction between those propositions which a man receives without evidence, and those which he only receives upon the strength of evidence. The first they denoted by the word *opinion*, the second they marked by the names of *knowledge* and *certainty*. "As error," they said, "is every thing which is not truth, in like manner, what is not *evidence* is only *opinion;* and whatsoever is only opinion is arbitrary, and liable to change. It is evident, therefore, that these opinions are not a sufficient foundation for the natural and essential order of societies. A solid edifice cannot be erected on a basis of sand; and that into which nothing arbitrary can enter, which is and must be unchangeable as the ends to which it is directed, can never be founded on a principle so arbitrary and various as opinion; opinion which, however just and true it may accidentally be, so long as it is not founded on evidence, is but opinion still, and liable every moment to be subverted and expelled by any other opinion, however extravagant and absurd."

Evidence is the knowledge, clearly attained and possessed by ourselves, of all that is necessary to see the truth or falsehood of an object of belief. This excludes all doubt, all uncertainty, every thing arbitrary, all exercise of will. A man can no more help believing that which he actually holds in his mind evidence sufficient to prove, than he can help seeing the object which is painted on his retina.

From this irresistible power of evidence the economists deduced the most important consequences. "Not only is it," they said, "the essential characteristic of evidence to stand the test of the most severe examination, but the most severe examination can have no other effect than that of displaying it to more advantage; that of giving to it a power more predominating and supreme; while, on the other hand, sufficient examination destroys prepossession and prejudice, and establishes in their place, either evidence, or at least suspension of judgment, where evidence on which to found a judgment is out of our reach."

On the first of these propositions, that "evidence can stand the test of the most severe examination," they said, "that all attempt at proof was surely unnecessary,—it was self-evident; and hence," they said, "was evidently deduced this most important consequence, 'that the liberty of examining, of criticising, and of contradicting evidence, is always and necessarily without inconvenience.'"

"That a sufficient examination destroys prepossession and prejudice," they regarded as a proposition equally indisputable; and from this it followed, as an irresistible consequence, "that the most unbounded liberty of examination and contradiction is of primary and essential importance; for no examination can be *sufficient* till all the reasons of doubt are exhausted."

"That a sufficient examination establishes evidence in the place of error in the case of all questions where evidence is within our reach," was a truth, they said, resting on the same immoveable basis; and from this it followed, as an evident consequence, "that liberty of inquiry will lead by necessity to the clear and public knowledge of what is the best possible order of human society; for on this subject evidence is undeniably within our reach."

"We may thus regard evidence as a sort of beneficent divinity, whose pleasure consists in spreading peace on earth. Never do you behold mathematicians at war with mathematicians on account of the truths which they have established on evidence; if they enter into a momentary dispute, it is only while they are yet in the avenue of inquiry, and have investigation solely in view; but as soon as evidence has pronounced either on the one side or the other, every man lays down his arms, and only thinks of enjoying in peace the good which is thus acquired in common."

"Pass now," say the economists, "from the evidence of *mathematical* to that of *social* truths; to the evidence of that order of human affairs in society which would produce to men the greatest possible amount of happiness. From the known effects of evidence in the first of these cases, try to conceive what would be the effects of it in the second; what would of *necessity* be the internal condition of a society governed by that evidence; what would of *necessity* be the political and respective situation of all nations if they were illuminated by its divine effulgence; consider if men, rallied under the standard of that evidence, would have any division among them; if any motive for war would be sufficiently powerful to make them sacrifice to it their best, and to themselves *evidently* best possible condition: penetrate still deeper, and see if the pictures which that medium presents to you do not excite in you sensations, or rather transports, which elevate you above yourself, and appear to indicate that, by means of evidence, we communicate with the divinity.

"But to increase your sensibility to the impressions which those pictures will make upon your understanding and your heart, place in opposition all the inconveniences which, in a state of ignorance, arise from the force of *opinion*.

"A certain thing is forbidden under the sanction of punishments capable of inspiring the greatest terror. What power can such prohibition and punishments have against an opinion which tends to despise them? None; we have too many examples to prove it.

"A man is placed by his birth in a situation in which he might effect the happiness of a great number of other men, if he made a beneficent use of his advantages; what is it the man performs when his *opinion* is wrong? He sacrifices his advantages to the disorder of his opinion, lives and dies unhappy.

"One man unarmed commands an hundred thousand with arms in their hands, of whom the weakest is stronger than he. What constitutes his power? Their opinion; they obey him in obeying it; they follow their leader because they have an opinion that they ought to follow him.

"Do you wish to see other effects which characterize the force of opinion? Consider the effects of honour; of that sort of enthusiasm which prefers toil and fatigue to repose, poverty and privation to riches, and death to life, on which it finds the secret of shedding a lustre.

"*Opinion*, of one sort or another, governs the world. Even when it is but a prejudice, an error, there is no power in the moral world comparable to its power. Fruitful in phantoms, it borrows all the colours of reality, in order to deceive. Source inexhaustible of good and of evil, it is through it alone that we see, by it alone that we will and we act. According as it borders upon truth or falsehood, it produces virtues or vices, the great man or the villain. No danger stops it; difficulties render it more intense; at one time it founds empires, at another destroys them.

"Every man is therefore a little kingdom upon the earth, governed despotically by opinion. He will burn the temple of Ephesus, if it is his opinion that he should burn it; in the midst of the flames he will brave his enemies, if his opinion is that he ought to brave them. Our physical powers themselves are so completely subordinate to the power of opinion, that, to have the command of our physical powers, it is necessary to begin by having the command of our opinion; but how is it possible to have the command of opinion, while it is the sport of ignorance, and its nature arbitrary? How is it possible to fix and to unite the opinions of men, but by the agency of evidence? Is it not visible that the Author of nature has appointed no other means for chaining our arbitrary will?

"We ought to look, therefore, upon ignorance as the necessary principle of all the evils which have afflicted society; and upon the knowledge, that is, the evidence of the best possible order of society, as the natural source of all the good which is destined for the inhabitants of the earth.

"But as all the physical forces in the world cannot render that evident which is not so, and as evidence can spring from nothing but *adequate examination*, from the necessity of that evidence clearly follows the *necessity of examination*, from the necessity of examination clearly follows the necessity of the *greatest possible liberty of contradiction*, and, in addition to that liberty, the existence of all those political institutions which are required to give to evidence its greatest possible *publicity*."

The *publicity of evidence* was a subject on which the economists dwelt with peculiar emphasis, and which they branched out into a number of the most important consequences. "The necessity of it," they said, "was apparent from this, that the proper order of society cannot be solidly established, but in proportion as it is sufficiently known. In any society, if some men only had knowledge and evidence of this order, while the multitude rested in other opinions, it would be impossible for this order to govern; it would in vain command; it would not be obeyed. This state would be that of a perpetual intestine war of one part of the nation with another. By *intestine war* they did not, however, mean," they said, "only that which is performed with arms in the hands, and by open force; they more peculiarly referred to those disguised and clandestine ravages and oppressions, exercised under forms of law; to those dark and predatory practices, which sacrifice all the victims which artifice is able to bring within their power; to all those disorders, in a word, which tend to make all particular interests enemies of one another, and thus to uphold, among the members of the same political body, an habitual war of clashing interests, the contending effects of which tear in sunder all the bonds of society. This situation is so much the more dreadful, in as much as, excepting the superior and governing force of evidence, there is no power in nature equal to that of opinion; as in its aberrations opinion is tremendous, and as no means exist by which we can make sure of retaining it always within proper limits, when it is once given up to its own inconstancy, and to seduction.

"From the *publicity*, which is an indispensable condition to possession of evidence respecting what is best in the social order, we are conducted to the necessity of *public instruction.* Though faith," said the economists, "be the gift of God, a peculiar grace, which cannot be the work of men alone; nevertheless it is held that the preaching of the gospel is peculiarly necessary to the propagation of the faith. Why, then, should not every one have the same opinion with regard to the publication of the social order, more especially as that publication has no need of being aided by grace and supernatural light? This order is instituted for men, and all men are born to live under it; it is then required by this order that men should know it, and accordingly they have all a sufficient portion of natural faculties, to be able to elevate themselves to that knowledge. For the same reasons that knowledge is required, instruction is required, by which alone certain kinds of knowledge can be attained."

The economists did not enter into details respecting establishments necessary for instruction. They, however, affirmed, that such establishments "constituted a part of the essential form of a society, and that they could hardly be too numerous, because instruction can never be too common." They affirmed, also, that "verbal instructions did not suffice; that it was necessary to have doctrinal books, suited to the purpose, and in every body's hand. This help," they said, "was so much the more important, as it was clear of all inconvenience, for error cannot stand in the presence of evidence; and contradiction is not less advantageous to evidence than it is fatal to error, which has nothing to fear so much as examination."

What they affirmed with respect to the necessity of those which they called doctrinal books, and of the liberty which ought to reign with regard to them, "was founded," they said, "upon the very nature of that order which is due to society, and of the evidence which belongs to it. That order," they observed, "is either perfectly and evidently known, or it is not. In the first case, its evidence and simplicity render the formation of heresies on the subject of it altogether impossible. In the second case, men cannot arrive at knowledge or evidence, but through the conflict of opinions. It is certain that an opinion can be established only upon the ruins of those which are opposed to it; it is further certain, that every opinion which is not founded upon evidence will be contradicted, until it is either destroyed, or recognized on evidence for a truth, in which case it ceases to be a bare opinion, and becomes an evident principle. And thus, in the pursuit of truths, capable of being established on evidence, the conflict of opinions leads, of necessity, to evidence, because it is by evidence alone it is capable of being terminated."

This doctrine is of such infinite importance, that we are willing to prolong it, by adding the illustration which the economists were accustomed to adduce. "If a man should be actuated by any motives to write a book endeavouring to persuade his countrymen that they might live without subsistence, that they ought to make commodities without the materials, that they multiply themselves by change of place, or any other extravagant opinion, it would be highly useless for the public authority to give itself any concern or labour to prevent such a book from making an impression upon the public mind; and, far from feeling any alarm, every body would rest securely upon the evidence of the contrary truths, assured that this evidence would always be sufficient for itself, and would quietly triumph over all the ridiculous efforts which would be made to oppose it.

"So absolutely necessary is it to leave to the whole body of society the greatest possible freedom of examination and contradiction; so absolutely necessary is it to abandon evidence to its own strength, that there is no other power which can supply its place; physical power, of what magnitude soever, can command actions alone, never opinions. The experience of every day affords to this truth the evidence of the senses. So little have our physical powers any influence over our opinions, that our opinions, on the contrary, exercise an uncontrollable dominion over our physical powers. Our physical powers are put in motion, and guided by our opinions alone. The common or social, called the *public force*, is formed by the union of the physical powers of many individuals. This supposes, necessarily and invariably, a correspondent union of evils; and this can never exist but in consequence of an union of opinions, good or bad. It is, therefore, to reverse the order of things, and take the effect for the cause, to desire to give the public force a power over opinion, while it is from the union of opinions that public force holds its own existence, and while, by consequence, it can have no stability but in proportion to that which reigns in the opinion on which it is founded, that is to say, in proportion as bare opinions, stripped of evidence, are replaced by opinions fixed and invariable, because founded upon evidence which cannot deceive."

3. *Laws.* Having established as incontrovertible truths, that property is necessary to the production of the means of human life and enjoyment, that the system of human rights and duties spring from it as natural consequences, and that the natural and essential order of societies is nothing in reality but the chain or connected order of these same rights and duties, the economists laid down the following definition: "That the essential form of a society is the continuation of all those social institutions which are necessary to consolidate the right of property, and secure to it all the liberty which essentially belongs to it."

Among these instrumental establishments, an important place is held by laws, of which they communicated the following very striking and original idea.

"A multitude of men assembled without acknowledging any respective rights, any reciprocal duties, would not form a society. That does not consist in the meeting of a number of men in a particular place. It may subsist among men very remote in respect of place, and not subsist among men very near in respect of place. *That which really constitutes the union, are the conditions of the union.* These conditions are the systems of rights and duties, in other words, the conventions entered into for their common interest by the members of the associated body. The laws, then, are precisely those conventions, by operation of which, the reciprocal rights and duties are established in such a manner that the members of the society are no longer permitted arbitrarily to depart from them.

"Of these conventions, some are of such a nature as cannot be defined very exactly, or at least cannot be enforced by artificial sanction, but must be left to the natural coercion of the approbation and disapprobation of mankind. Such are the common duties of morality; gratitude, veracity, charity, and the like. But the next class of these conventions are those which are capable of being defined exactly, and enforced by artificial sanctions; as, that murder shall not be committed, property shall not be stolen. This last class of conventions are those which are properly called *laws.*

" The first property necessary to give those laws their best possible *form* (for, in regard to their substance, it is always supposed that they are strictly conformed to that utility from which the whole system of rights and duties takes its origin) is, that they be definitive; to distinguish, by an incontrovertible line, what each of them does, from what it does not, comprehend. This is implied in the very notion of a law, which is to render something *positive,* which would otherwise be *arbitrary.*

" The second property necessary to give laws their best possible form is, that they be written. This is indeed implied in the first property; because no combination of ideas can be rendered *positive* and *unvarying,* of which the *expression* is not *positive* and *unvarying.* But nothing can render an expression positive and unvarying but a permanent sign; and, of permanent signs, none is equal to writing.

" The third property necessary to give to laws their best possible form is, that the reason of each be annexed to it. The distinction is very important between the *letter* of the law, and the *reason* of the law. The *letter* of the law is its textical composition; the *reason* of the law is the motive by which it was dictated. *The man who is guilty of murder shall receive a certain punishment.* This is the *letter* of the law. The *reason* is, that *if murder were common, and not restrained by adequate motives, the happiness of human beings, if not the species, would soon be destroyed.* Having thus acquired a knowledge of the reason of the law, I possess the *evidence* of its *utility.* And of this I should not have been possessed, had I seen in the law nothing more than the *letter.* Let us suppose two laws, which equally assign the punishment of death; the one for homicide, the other for walking at certain hours in the day. Is it not clear that they would be viewed with different eyes; that the one would appear to be just, the other tyrannical; that we should feel within ourselves a natural disposition to submit to the one, a disposition to avail ourselves of every thing which might serve as a means to deliver us from the hateful yoke of the other? This difference arises from the different judgment we form of the *reason* of these bad laws. The first carries with it the *evidence* of its *utility;* and that *evidence* overcomes and binds without resistance the understanding and the will. The other carries with it, instead of the evidence of utility, the evidence of nothing but a disproportional rigour, of a manifest evil, to which our understanding, and consequently our will, can never submit.

" It is not, therefore, in the *letter,* but in the *reason* of the laws, that we must seek for the first principle of a constant submission and obedience to the laws; for that principle can be nothing but the dominion exercised over our minds by the *evidence* of the justice of necessity, that is, the *utility* of the laws; now this evidence is not in the *letter* of the laws; to establish that submission, therefore, generally and invariably, two conditions are requisite; one is, that the reason of the laws contain conclusive *evidence* of their *utility,* commonly called their justice and necessity; the other is, that the publication of this evidence be so complete, in respect both of clearness and diffusion, as to lodge it in the mind of a majority of all classes of the people. Men, persuaded that their laws were bad laws, might indeed for a time be constrained to observe them; but such a submission, contrary as it is to nature, could not be durable, nor escape daily breaches on the part of those who regarded themselves as suffering by the injustice of the laws. *Submission to the laws is always, and necessarily, proportional to the idea which we hold of their justice and necessity;* that is, their indispensable use in procuring good and eschewing evil.

" If laws," said the economists, " are any thing but the results of the natural order of society, or of that system of duties and rights which are rightly founded upon the interest of all; if the legislature of any country sets up rights and duties of another sort, these new rights and duties are contrary to the first; and hence, of necessity, the laws which prescribe them are in a state of perpetual opposition with our understandings and wills." This contrariety they proved in the following manner: " All the rights which a reasonable being can desire are summed up in that of property; because from the right of property results the liberty of enjoying; a liberty which ought to have no bounds but those which are assigned to it by the similar rights of property belonging to other men. As the essential order of society thus determines the measure of liberty belonging to each of its members, and as that measure is the greatest which can be, without disturbing that essential order itself, it is impossible that any thing should be added to the liberty, that is, to the rights of one set of men, without taking from the liberty, and by consequence from the property, of other men; and this is an injustice and disorder, the tendency of which is destructive to the society."

It is destructive to the society, because it throws it into a state of violence. " My neighbour," says Mercier de la Rivière, " will be content that he is not allowed to reap or to injure my crop; but for the same reason he will not be content that I should be allowed to reap or to injure his. On the view of such an injury permitted in regard to any other man, he will take the alarm, his fears will be excited for himself, and this anxiety will be a state of torment, from which his reason will perpetually urge him to seek relief. A law which violates the principle of utility, is a law therefore resisted by that evidence which governs beyond control the human will. To make such a law, is to put the society into a state of violence, because it is to put the minds of men into a state hostile to one another, and more or less hostile to the laws.

4. *Magistrates.* By this term the economists understood judges, and, in a word, all the leading functionaries employed in giving execution to the laws. Agreeably to the doctrines already exhibited, they conceived that the first service of the magistrates is that of shedding the light of *evidence* upon the particular cases which have been too obscure for the parties. But as there are some minds with which you cannot be sure of being able in every case to bring evidence, as it were, in contact, the magistrate needs to be armed with a coercive power; and all that is necessary is, that he affords to the rest of the community *evidence* that in such cases the power has been used agreeably to the principle of general good.

From these premises, the chief consequence which they deduced was, that the legislative and judicial powers are never to be united in the same hand, without destroying among the people all certainty of the justice and necessity of their laws, that is, the very essence of the laws themselves.

" The essential form of positive laws," they said, " in that which makes them to be what they ought to be, is, that they consist of certain visible signs, which show, that in the institution of them, that order has been followed which is necessary, 1*st,* to ensure their justice and necessity, that is, their adaptation to the ends of obtaining good and avoiding evil; 2*dly,* to render their adaptation to those ends evident or certain to the individuals whom they concern. Now it is clear that these conditions could not be fulfilled if the legislative power was to engross the judicial functions. The legislator and judge being the same person, neither could the legislator find any resource against his own mistakes in the close review and experience of the judge; nor, on the other side, could the arbitrary will of the judge find any bridle or chain in the authority of the legislator; but the laws, however good in themselves, would be rendered evil by a variable and corrupt administration.

"If the legislator were judge also, his business would be to consummate and to crown all the mistakes which he incurred, or the abuses which he committed, in the formation of the laws. If the judge were legislator also, the laws existing only in conformity to his will, he would be under no necessity to consult the laws in passing his judgment, and would always ordain as law-maker, what he should have to determine as law-interpreter. Thus the *reason* of the positive laws would be found to consist in nothing but the will of the legislator, as he would be guided in making them by nothing but its arbitrary impulses; and, in the same manner, the *reason* of the judicial decisions would be found to consist in nothing but the mere will of the judge, whose independence would enable him to make them whatever he pleased. This double malady abundantly proves that those laws would be stript of the essential characteristics of law, the evidence of their justice and necessity, and an absolute exemption from every thing arbitrary."

The duties of the judge they deduced in the following order: As the laws are in themselves mute, and the magistrate is the organ through which they speak, he is particularly charged with the *guardianship* of the laws. It is of importance to know what is implied in the term guardianship of the laws. It relates either to the laws which *are* made, or to those which are *to be* made. The natural strength of the laws consists in the evidence of their goodness. Their weakness consists in the strength of the hands which dispose of the physical power. As the laws are mute in themselves, they cannot wield that evidence in which their strength consists. The magistrates, who are the mouth of the laws, ought therefore to wield it for them, and to resist the hands in which the physical power is deposited, when they attempt the infringement of the laws, with all the force which evidence can be made to exercise over the minds of the community.

The same principles demonstrate what are the duties incumbent on the depositaries of the judicial power with regard to laws *to be* made. As laws ought all to be founded on that concatenation of the causes of human good which the economists denominated "the primary and essential reason of all laws, the *evidence* of that primary and essential reason was," they said, "a deposit, so to speak, in the hands of the judicial instruments, of which they owed an account to the legislature, to the nation, and to God himself, of whose supreme will that evidence is the decisive token. It was their first duty, therefore, to have a perfect *knowledge* of that primary and essential reason." Their next duty was, on all occasions, as far as their utmost efforts could extend, to impart that evidence to the governing power, and to make it as clear as it can be made, what laws, not yet proposed, that evidence shows that the society requires.

The economists further affirmed, "that no man can, without rendering himself criminal towards earth and heaven, undertake to perform the office of judge, according to laws that are *evidently* unjust. He would in that case cease to be a minister of justice, in order to become a minister of iniquity. If any law, for example, ordained that a man should be condemned to the ultimate punishment, on the mere denunciation of another man, and without any inquiry into the truth of the allegation, is it not evident that such a law would be a law of murder? And is it not equally evident, that the barbarian who should pronounce a judgment agreeably to that law, would be the voluntary instrument of murder? It is necessary, however, either to go the full length of saying that a man can, without guilt, become the instrument of such a law, or allow that no minister of the law ought to lend his ministry to the execution of a law evidently unjust; for if he may for one such law, so he may for all, however atrocious; no outrage to humanity, no excess of evil, presents any limiting point."

5. The *tutelary authority*. "The union of wills to form that of individual powers; the union of individual powers to form a common or public force; the deposit of that force in the hands of a chief, by whose ministry it may command, and make itself obeyed,—these," said the economists, "are the component parts of the tutelary authority. The tutelary authority is nothing more than a physical force resulting from an union of wills; and, by necessary consequence, it is impossible for it to be either powerful or secure, unless the intuitive and determining force of evidence be the principle of that union.

"In one sense, it may be affirmed that the right of commanding belongs to evidence alone; for, in the order of nature, evidence is the only rule of conduct bestowed upon us by the Author of nature. But all men are not equally capable of seizing evidence; and even if they were, the interest of the moment often operates upon them with such vehemence, that the appetite of enjoyment will not, in a state of disorder, be restrained by the evidence of duty. Among human beings, therefore, it is necessary that the natural authority of evidence be armed with a physical force; and that the legislative power, though it commands in the name of evidence, have the disposal of the public force to ensure obedience to its injunctions."

From the analysis of what is necessary to constitute the tutelary authority, the key-stone, as it were, of the arch of human society, that which gives to the whole its binding force, and retains the parts in their order, the economists deduced a variety of most important conclusions, of which we can only present the more striking as a sample.

The first is, that the legislative and executive powers are essentially inseparable, and that all the fine-looking theories, which have solicited and obtained so much of the admiration of a superficial world about the virtues of their separation, are phantoms in the air, the mere visions of imagination. "To dictate laws is to command; and as our passions render it impossible that commands should be more than useless sounds without the physical power of making them obeyed, the right of prescribing laws can have no existence without the physical power of enforcing them. The depositary of the power is, therefore, and necessarily, the master of the right; and the executive power is always and certainly the legislative power. Let the enemies of this conclusion turn and torture the subject which way they please, they never can escape from it. Suppose, in order to form two powers, that the legislative right is confided to one organ, the public force to another, when opposition arises, which of the two is to be obeyed? As it is impossible that two contradictory commands can be obeyed at the same time, it must be absolutely decided which of the two is in preference to be obeyed. Now, this decision is, by the very fact, the destruction of the other power, and the establishment of that one. These two powers, therefore, unavoidably run into one; the legislative power necessarily becomes the executive power, or the executive becomes the legislative.

The second is, that the legislative never has, never can have, a right to make *bad* laws. A right to make bad laws, they said, is a contradiction in terms. A right supposes a *compact;* it is the offspring of an agreement, tacit or express; the idea of it can no more exist without that of a mutual convention, than a debt without the contract of debtor or creditor. The compact upon which all rights are founded is that of mutual advantage; it is the union of all wills, freely determined by a great interest, of which the *evidence* is visible to all. How can that union which only exists for the sake of a good continue to exist if it is seen to produce evil? The hope cannot be framed of maintaining it by force, because force is its effect; force can exist only subsequent to union, and in consequence of union. The horrid prerogative of being able to make bad laws supposes necessarily a state of ignorance, a state in which the vices of the laws are not illuminated by evidence; for it is impossible that a community should consent to uphold that which visibly hurts them. The power exists in this hateful situation, but the right as little there as anywhere else.

The economists come next to the important question, What is *the security for the right use of the legislative power?* On this subject their anxiety to secure to their opinions the benefit of publicity, and the favour of those in whose hands the governing powers were actually deposited, led them to use the veil of expressions too general, and into some positive mistakes. "The security," they said, "for the right use of the legislative power, is the interest of that same power, which can, in the general order alone, find its own best possible state. The irresistible force which evidence acquires by publicity is also that security. This evidence exists in its greatest force in the body of the magistrates, who cannot, without ceasing to be ministers of justice, lend their ministry to the execution of laws evidently unjust; or forbear, without being criminal, their utmost endeavours to make the *evidence* of that injustice as clear as possible both to the legislature and to the nation."

The grand question followed, *What are the hands in which the legislative power ought to be deposited?* Having demonstrated that the legislative and executive powers cannot by possibility exist in any but the same hands, and that they form together what they denominated the *tutelary authority*, they proceeded to inquire what was implied in the idea of authority. "Unite," said they, "upon one object a multitude of opinions and of wills; from that union will arise naturally and necessarily an union of physical forces for the accomplishment of those wills; and from the whole together will result an authority, or, in other words, *a right of commanding, founded upon a physical power of procuring obedience to what is thus commanded.* If these opinions and wills should disunite, and form, for example, two parties, the forces will for that reason be divided; there will be two forces, two authorities, and, by consequence, two societies. That two authorities cannot exist in the same society, they maintained by the following proof. Such authorities must be either equal or not equal. If equal, each of them taken separately is null. If unequal, the superior is the real and only authority. That, in the first case, each taken separately would be strictly and literally null, arose, they said, from the very nature of equality, which rendered it absolutely impossible that the one could do any thing without the other. Neither of them, therefore, could procure a single act of obedience, except by their union; but, at the very moment of their union, they cease to be two authorities, and form both together only one authority made out of the union of both. Unity is, then, a part of the very essence of authority; to divide it is to reduce it to an incapacity of acting, that is, to extinguish it; for authority is not authority but in so far as it can act to procure the execution of its will."

From the necessary unity of the tutelary authority it followed, they said, by necessary consequence, that the organ of that authority must be one man. That the physical force which is one of its component parts can be directed only by one will, is above the need of proof. But it is said that one will may be formed out of the union of several wills, and that the public force is not subject to the separate wills till the union takes place.

To this the economists made answer, that if the opposition of one will can suspend the effect of all the others, it reduces authority to inaction, and for that reason destroys it. The reason why physical force is necessary is, that you cannot count upon the union of all wills. If, to avoid this objection, you have recourse, they said, to plurality of suffrage, you build no longer on the basis of evidence. That which divides opinions is not yet evident. As nothing in government ought to be arbitrary, and every thing that is not arbitrary is founded on reasons, that is, *evidence*, there cannot be diversity of opinions on matters of government, except from the effect of ignorance, or of bad design on the part of the deliberants. But it cannot be determined by a few voices less or more, on which side the ground of evil lies. Experience shows that an accredited error may long unite partizans in much greater number than the truth by which it is opposed. The number of those who concur in an opinion cannot render that evident which is not evident; their opinion is only opinion still, which is of course subject to change; for nothing but evidence is unalterable. And with respect to bad design, as that results from particular interests, it can never be determined whether the number of those whom such interests command is the greatest or the least. On both accounts, then, plurality of suffrage is not security.

But the greatest evil, they said, of the mode of determining, by majority of votes, the question respecting the social order, was, that it set individual interest in opposition to public; in which case the public interests are sure to be sacrificed. "How great soever the differences among men, they have within them, nevertheless, two grand moving powers common to all, and which are the source of all their actions—the appetite of pleasure and the aversion to pain. To suppose that men can move in opposition to those powers, is to suppose that the cause can depend upon the effect. But the desire of enjoyment, and opinion by which it is modified, cannot act naturally and constantly in the direction of the public interest, when authority is divided among several persons who are liable to have interests opposite to one another. For it may be laid down as a truth which will not admit of contestation, that the public interest cannot be considered as generally safe when it is in opposition to the private interests of those who are entrusted with it. If one or more of the public administrators behold any great advantage to themselves in a sacrifice which has been made, or which may be made, of the public interest, we ask, said the economists, What can prevent the sacrifice from being made? Not the two springs of action which nature has placed within us to be the cause of all we do; for they are in this case put in opposition to the public interest. Not any other authority in opposition to that of the public administrator, since by the supposition they themselves engross the whole of the governing power."

The remaining evil which the economists ascribe to this expedient was, that it attached to the number of votes a despotical authority, which can safely and usefully belong to *evidence* alone. "Under this system it is not evidence," they said, "which governs; it is opinion, or the will of a certain number of men actuated by the same opinion.

The mischief apt to result cannot be estimated; it is without bounds. Suppose, in fact, that the vote of the majority is dictated by private interests, and that *evidence* is on the side of the minority, is it not monstrous that the former should command, and that the form of the government should lend to bad design a title to triumph over evidence itself? This excess of disorder is nevertheless inevitable under so defective a plan of government; and the nation remains absolutely without protection against the scourges with which, under private interest set in opposition to public, it may be lacerated, especially if these private interests are the interests of men who, by their riches or otherwise, are in possession of power.

"We forget not," they said, "that the mischievous tendency of private interest would find a counterpoise in the *knowledge of the nation.* It is very true, that in a nation really enlightened, a nation that had from *evidence* the knowledge of its own true interests, the body of rulers could not abuse their authority. But why? because the evidence of the abuse would in that case annihilate the authority. But the idea of a nation governed by plurality of suffrage, and by evidence at the same time, involves an absurdity. Again, a nation sufficiently instructed to know all the links in the chain of social good and evil, would never sanction a form of government which places the common interest in opposition to the private interests of those to whom it is entrusted. Besides, it would be ridiculous to suppose a nation sufficiently instructed to have the wills of all united under the evidence of what is best in the social order, and to suppose its rulers at the very same time so ignorant as to be divided on those subjects, and reduced for a ground of decision to plurality of suffrage.

"So long, on the other hand, as a nation is not thus instructed, the people properly so called, sunk in ignorance and prejudices, see no farther than the nearest objects by which they are surrounded; each canton thinks the interest of the state is all summed up in the interest of that canton; each profession in the interest of that profession; the knowledge of relations and dependencies is absolutely wanting. Such men cannot ascend from effects to causes, much less enumerate the links in the chain of causes and effects. It becomes, therefore, morally impossible for them to act by principle and by rule. Ever credulous, and prone to prepossession, they must be gained in order to be persuaded; the same artifices must be practised upon them which are used to seduce them. The resolutions of men, the sport of momentary impressions, must have all the inconstancy of these impressions. Divided into rich and poor, the rich look upon the poor as made for them, and upon every power which they wish to possess as naturally their due. The poor, justly discontented with the treatment they receive, and mistaking the cause, are tempted to envy the condition of the rich, and to regard as injustice the inequality of the partition which is made between them. It is evidently, therefore, unsafe to choose the body of administration exclusively from either of these two classes. Nor would much be gained if one half were chosen from the one and the other from the other. If the separate portions continued to be governed by the prejudices and views of the classes to which they belonged, they would do nothing but contend; and there is only one way in which they could receive a motive to cease,—*if collusion would enable them to serve their own private interests by sacrificing the interests with which they were entrusted.*"

The economists come then to their grand conclusion with respect to the artificial or physical security of the social order. To the question, what is the best form of government, they answered, the government of a single individual, uniting in his own person the whole of the legislative and executive powers; in other words, absolute. "All men," they said, "would confess that the best form of government was that which was so perfectly conformable to the natural and essential order of societies, that no abuse could result from it; that form, in short, which renders it impossible to make gain out of misrule—which subjects him who governs to the absolute necessity of having no greater interest than that of governing well." This advantage would be found, they affirmed, in the government of an hereditary sovereign, and it would be found in no other.

The reason was, that in no other could the interests of governor and governed be rendered absolutely the same. As the hereditary sovereign is the hereditary proprietor of the sovereignty, the interest of the sovereignty is his interest. The interest of the sovereignty means the most perfect possible state of the governing authority; that is, the most perfect possible assurance of obedience to its command. But obedience to command can only arise out of the union of wills. And there can be no perfect assurance of the union of wills to obey but from one cause; the evidence that what is commanded is for the benefit of those who are to obey. The interest of the hereditary sovereign, therefore, and the interest of the community, is one and the same.

With regard to the famous idea of the *balance* of a constitution, that fancied arrangement of things in which the power and will of one part of the instruments of government finds a counterpoise in the power and will of another; this pretended counterpoise the economists treated as a perfect chimera, a mere imposition of the imagination, a sort of day-dream.

The nation, they said, is either instructed or not instructed. Let us examine the supposition of the balance in both cases. If it is instructed, or, in other words, possesses the evidence of the causes of good and evil in society, there is no balance of forces; there is only one force, because force follows will, and here wills are united. They carry the development of this idea to a great length, to which our limits will not permit us to follow them.

If the nation is not instructed, or, in other words, does not possess the evidence of the causes of good and evil in society, the establishment of counter-forces is impracticable. To ignorance there can be only one salutary counteracting force, and that is evidence. The effect of ignorance in the sovereign is dreaded; and to remove the dread, another man's ignorance is provided. This is what people call making counter-forces. It must be confessed that they are not of the very best sort of materials. How could it ever be imagined that confidence for any thing stable could be laid on any thing so unaccountable as the results of ignorance?

Let us adopt this chimera for a moment, and ask if it be possible to assure ourselves that each force will be the same to-morrow which it appears to be to-day. It is evidently impossible; nay, what each appears to-day may be a *false* appearance; for, resting only on opinion, detached from evidence, it rests on what can never be exactly known.

The idea of a balance is the idea of two powers, one tending by its own force in one direction, another urging it by an equal force in an opposite direction. The effect is rest. To balance the power of the sovereign acting in one direction, you provide another power acting in an opposite direction. If the powers are equal, they destroy one another, and there is no action. If they are unequal, there are not two powers, but only one power; for the greater swallows up the less.

The theory of a constitutional balance is founded on a metaphor, a contrivance of language; and moral forces are supposed to be subject to the laws of material forces. Material forces acting on a body in different directions, make it assume a certain determinable duration between the two. But it has not been considered, that in physics the direction given does not depend upon the opinion of the things which act. In morals, on the other hand, the things which are depended upon for counteraction change their duration according to their opinion. A theory which supposes that to be uniform and constant which is known to be the reverse, is evidently absurd.

Suppose every thing which the theory needs to be supposed. Conceive an assembly, or assemblies, provided to counteract the sovereign, and so constituted, as to form the most perfect counteraction possible; that the sovereign can ordain nothing but with the consent of the assemblies, and the assemblies nothing but with the consent of the sovereign. In this case, it is not a government of one, but a government of many; each member of the assemblies shares in the sovereignty; they are so many partners, therefore, with a particular partner at their head. The question is, what are the interests of the partnership? Those of the nation or not? The interests of the partnership doubtless are, to make it as profitable to the members as possible; for it would be absurd to suppose them not governed by their private interests. Suppose, then, that there is originally a tendency to counteraction between the sovereign and the assemblies. It is very obvious that they will put an end to this counteraction, as far as they discover that the suspension of it is conducive to their private interests. This is a law of nature, and may be taken for granted. As far, then, as the serving of the private interests of the members is concerned, there is no balance of opposite forces; the forces combine instead of opposing, and so far the balance is lost. The loss of the balance to this extent may be a loss engrossing the whole of the protection to the common interest which it was expected to yield, or it may be a loss not extending so far. If it goes to the whole extent of that protection, there is to the purpose in question no balance at all. If it does not go to the whole extent, there will still be some balance, more or less. What then is the case? The case is, that the loss goes to the whole, and that the balance does not exist. The balance does not exist, as far as the private interests of those who share among them the governing powers are concerned. But it is only from the private interests of those who govern that the nation has any thing to fear; it is only against these interests that the balance is provided. As far, however, as these private interests are concerned, the balance does not exist. As far, therefore, as the balance is even *supposed* to be of any service, the balance is excluded by the law of nature. It follows as a corollary, that in a country where the people depend upon what is called *a balance* as the whole of their security for good government, they have no security at all.

Such is the analysis which the economists present of the causes of good and evil in human society, and of that order of things which best insures the presence of the one and the absence of the other. That part of their doctrine which alone is yet known to the mere English reader, their *Political Economy*, is introduced as only an auxiliary exposition. It is part of the development by which they endeavoured to prove the identity which they supposed between the interests of the sovereign and the interests of the people. But, as a very distinct account of this part of their system has been given by Dr Adam Smith and other writers, and as our object rather was the exhibition of those doctrines of the sect which nobody has yet presented to our countrymen in their own language, we shall content ourselves with only marking the place which their political economy held in their general system.

As the society has public expenses, it is necessary that it also have a public revenue. To reconcile the formation of a public revenue with the idea of social order, it ought to be formed, if possible, without infringing the property of individuals, for the sake of which the order of society itself is established. It ought, therefore, if possible, to be formed without diminishing the revenue of individuals. When the real origin of revenue, the source from which it all is drawn, is sufficiently understood, the mode of forming a revenue for the sovereign, without diminishing that of individuals, would be immediately apparent. *The source of all riches is the land; because the land alone, of all the sources of production, yields a produce greater than the cost of the production.* The surplus produce of the land, therefore, constitutes a fund, which is over and above the remuneration to the agents of production, and out of which the revenue of the sovereign may be taken, without diminishing the motive to production; that is, without retarding the natural progress of the state in wealth, population, and felicity.

To lay the foundation for this plan of a public revenue, it was necessary to prove that the land is the only source of production; and that manufactures and commerce, though they alter the form of things, never add any thing to the amount or value of production. In the development of these views, one of the most remarkable results at which the economists arrived was the necessity of perfect freedom to all the proceedings which lead to production; as giving to produce that form which is most agreeable to those who are to make use of it. Till the time of the economists, the necessity of holding those proceedings in chains, and binding them to the will of governments, was the universal doctrine of governments, and, to a great degree, of speculators themselves. The general principles of the economists respecting the *freedom* of property necessary to constitute the foundation of social order, led them to infer the evil of those abridgments of freedom; but they examined the inference in detail, and showed that the meddling officiousness of governments to compel industry to one thing, and exclude it from another, not only failed to effect any good purposes, but of necessity created obstructions of the greatest magnitude to production in general, and tended powerfully to keep down the wealth, population, and prosperity of the state. The light which they diffused on this subject, and which soon produced a grand effect on the minds of men, was a good, the magnitude of which is beyond calculation.

Another of their conclusions is, that the revenue of the sovereign, taken, as they said it ought to be, wholly from the net produce of the land, ought to be a fixed and unalterable proportion of that produce. The reason appeared to them conclusive. If the proportion was variable, and depended upon the will of the owners of the land, they might be induced to break upon the public revenue, and deprive the state of those benefits which the public revenue is necessary to produce. If it depended upon the sovereign, the property of the land might be detached from that of its produce; nobody would have a motive to become a proprietor in land, and all the advantages which depend on the existence of that property would be lost the production of subsistence would fail, and the community could not exist.

This proportion being once fixed, there is no longer any contrariety between the interest of the sovereign and the interest of any portion of his people; and the proprietors of land are as completely and securely exempt from contributing to the expense of the state, as any other class of the community. The sovereign derives no part of his revenue from the subject; and this deplorable source of the conflict of interests is wholly cut off. The proportion being settled for ever between the sovereign and the land-owners, that alone is the property of the landowner which is the proportion remaining to him. The rest is, with regard to him, as if it did not exist. The sovereign they denominated, therefore, *co-proprietor* of the land; and between him and the landowner, commonly so called, a perfect community of interests is fixed. It is the interest of the sovereign that the produce of the land should increase, because, with every increase in the produce of the land, his revenue increases. It is also the interest of the landowner that the produce of the land should increase, because it is from the same cause that his revenue increases. See the article POLITICAL ECONOMY.

III. In the remarks which we have to offer on the doctrines of this sect, we must content ourselves with a few general strictures on one or two leading points.

The most important slips which the economists made in tracing the laws of the social order, are found in their deductions respecting the *tutelary authority*. Many steps, nevertheless, in that doctrine they have established. That the legislative and executive power are essentially the same, and cannot be separated except in *appearance*, they seem to us to have placed beyond the reach of dispute. That no security for good government can be found in an organization of counter-forces, or a *balance* in the constitution, they have proved in a manner equally satisfactory. But we think they have not proved that a security for good government can ever be found in the personal interests of a sovereign who unites in himself the whole of the legislative and executive power. And we think they have not proved that this security, if it cannot be found in the interests of such a sovereign, can be found in nothing else.

1. That the economists do not reason correctly from their own principles, when they regard the interests of the sovereign as an adequate security for good government, may be made apparent, we should hope, by an argument of a very few steps.

In a perfect state of the social order, they say that the interest of the sovereign would be the same with that of the community; and the evidence of this identity would be so clear to the sovereign, that the effect of it would be irresistible on his mind. But in a perfect state of the social order, they say also, that the interest of *every* man would consist in the most exact conformity to all the rules of that order, and that the evidence of this truth would be so apparent as to be sure of its effect. In the only state, therefore, in which the interest of the individual entrusted with the tutelary authority could be relied on as a security, the tutelary authority itself would not be required; for in a state in which every man would, of his own accord, do what is best, an authority to compel him to do so would be worse than useless.

The moment when you suppose a tutelary authority to be necessary, the moment at which you suppose there is any man in the community who can regard his private interest as consisting in any degree in what is hurtful to the community, how can you be sure that the depositary of the legislative and executive powers will not be that man? It can be easily shown that no man is acted upon by stronger forces to impel him in that direction.

In order to prove that the legislative power cannot be exercised by the community at large, the economists declare expressly, "that if we study the nature of each man in particular, we shall find in general that he would if possible have nothing but rights on his own side, nothing but obligations on the side of other men. The legislative power can be exercised with safety only by those who possess in perfection the evidence of the justice and necessity of the original and pervading laws of social order. It cannot, therefore, be exercised in safety by a body of men, among whom unequal rights exist, and must exist; and who at the same time are all separately desirous that the inequality should be in their favour."

Admit this—admit that all men in general desire to have nothing but rights on their own side, obligations on the side of other men; to have the inequality all in their own favour; to possess advantages, in short, over their fellows in the community; and it is surely absurd to talk of security in the interest of the sovereign.

It is a part of their doctrine, that he who is entrusted with the legislative power cannot be entrusted with the judicial power; because in that case the same party, both legislators and judges, would destroy law, by the exercise of arbitrary will. This is a direct admission, or rather an unlimited affirmation, that the interest of the sovereign is not a security such as good government requires. Again, it is said by the economists, "that under a government conformable to the principles of order, the positive laws would be of a justice and necessity *publicly evident;* and that in order to apply these laws, the judges would unite two sorts of knowledge, both of its meaning and of its reason; and, secondly, a knowledge of the facts which constitute the case in which they are required to decide." No men, according to them, are more urgently called upon, none can be more reasonably expected to be in full possession of the evidence of that interest which every man has in the preservation of the social order. Yet so far are the economists from saying that the interest of these men, and the evidence they could possess of that interest, would be a sufficient security for the right administration of their trust, that they declare them liable to the greatest malversations, and that the ultimate security would lie in the sovereign, who would check them. It is surely matter of wonder how the economists could fail to perceive, that the very same motives which they rejected as security for the right use of authority in the judges, they trusted to as complete security in the sovereign; though likely to operate on the judges with greater force than upon him.

2. We think it may also be made apparent, that the economists do not reason correctly from their own principles, when they conclude, that if security for good government cannot be found in the interests of one man entrusted with the whole of the legislative and executive powers, it can be found in nothing else.

They expressly state, that "the first, the real depositary and general guardian of the laws, is the nation itself, at the head of which is the sovereign. Accurately speaking, the deposit and guardianship of the laws *can* belong to those alone who are armed with the superiority of the physical force, to procure to that deposit its necessary superiority. This being evident, it is the nation as a body which naturally and necessarily is the depositary and guardian of its own laws; because there is in the nation no power comparable to that which results from the combination of its powers." Again,

In contending that the legislative and executive powers must always be exercised by the same hands, they affirm that those powers could only be exercised by those who had in their hands the superiority of the physical force. Observe, now, the legitimate conclusion:

The people alone have the physical force necessary to constitute them guardians of the laws. The same force is necessary for the makers and the executors of the laws. No body, therefore, but the people ever can, accurately speaking, have either the legislative or the executive powers. In a state of ignorance they may be led by fraud to lend their powers to their own destruction. But it is a part also of the doctrine of the economists, that in a state of knowledge, in which they may be easily placed, it is not possible they should make any but a good use of their power.

"A nation," they said, "governed according to the natural and essential order of society, has *necessarily* the perfect evidence and knowledge of it, and therefore sees with certainty that it enjoys its best possible situation. This perception, of necessity, unites all the wills and all the forces in the nation for the support of that order, and, by consequence, for the creation and preservation of all the institutions which are best adapted to that support." The people, therefore, may be safely trusted.

In a nation governed badly, governed not according to "the natural and essential order," but according to what the economists call the "*political* order," "it is always," they said, "one part of the nation which governs the rest; the weaker which governs the stronger. In this case, too, the power of him who commands consists in nothing but the powers united of those who obey him. And this union of their forces supposes, of necessity, the union of their wills; which can be founded only upon the persuasion that this obedience procures them their best possible condition. The powers of the nation in this vicious order are less at the disposal of the sovereign than at the disposal of those who hire to him their agency, and, by consequence, sell to him the means of procuring obedience from the nation; his situation is therefore at bottom a real dependence; his situation is precarious, uncertain, changeable; he is put in chains, which he dares not attempt to break." In every situation, therefore, it is the will of the people, either of the whole of the people united, or of a part of the people united against the rest, which is in reality both the legislative and the executive power. Estimate, therefore, as high as you please, exaggerate to any excess, the inconvenience of being governed by the people, you have that inconvenience still; you are bound to it by the inexorable law of nature; it is not within the range of possibility that you should escape from it.

We have already seen that the economists declare that "every man wishes to have all the rights on his own side, all the duties on the side of other men; that every man likes inequality, in short, when the inequality is in his own power." From this they infer, that the community cannot safely govern; but from this it may with much more justness be retorted upon them, that nothing else can safely govern. The interest of the community, say the economists, is easily known; the evidence of it is within the reach of all descriptions of the people, and so cogent as to be irresistible. The union of wills, according to their doctrine, follows as a matter of course. Here, therefore, it should seem we have a much better security than can be found in the interest of any *individual*, sovereign or subordinate.

It is remarkable enough that the economists have wholly overlooked, in their criticism on the plans opposed to their own, *the representative system;* and yet it is pretty evident that it is by means of the representative system that the grand problem of government must finally be resolved. The speculations connected with this subject will, however, find a more fitting place under the article GOVERNMENT. (A. A. A.)

ECONOMY, POLITICAL. See POLITICAL ECONOMY.

ECSTACY. See EXTASY.

ECSTATICI, Εκστατικοι, from εξιστημι, *I am entranced,* in *Antiquity,* a kind of diviners who were cast into trances or ecstacies, in which they lay like dead men, or persons asleep, deprived of all sense and motion, but who, after some time, recovering their senses, gave strange relations of what they had seen or heard.

ECTHESIS, in *Ecclesiastical History,* a confession of faith, in the form of an edict, published in the year 639 by the Emperor Heraclius, with a view to allay the troubles occasioned by the Eutychian heresy in the eastern church. However, the same prince revoked it, on being informed that Pope Severinus had condemned it, as favouring the Monothelites; declaring at the same time that Sergius, patriarch of Constantinople, was its author.

ECTHLIPSIS, among Latin grammarians, a figure of prosody, by which the *m* at the end of a word, when the following word begins with a vowel, is elided, or cut off, together with the vowel preceding it, for the sake of the measure of the verse. Thus they read *mult' ille,* for *multum ille.*

EDAM, a small and woody island on the coast of Java, about two miles in circuit, whither criminals are banished. It is nine miles north-north-east from Batavia.

EDAMBAVANUM, a town in the north of India, province of the Carnatic, situated on the western shore of the bay of Bengal. Long. 75. 55. E. Lat. 10. 27. N.

EDDA, a system of the ancient Icelandic or Runic mythology, containing many curious particulars of the theology, philosophy, and manners of the northern nations of Europe; or of the Scandinavians who had migrated from Asia, and from whom our Saxon ancestors were descended. Mr Mallet apprehends that it was originally compiled, soon after the Pagan religion was abolished, as a course of poetical lectures, for the use of such young Icelanders as devoted themselves to the profession of scald or poet. It consists of two principal parts; the first containing a brief system of mythology, properly called the *Edda;* and the second being a kind of art of poetry, and called *Scalda* or *poetics.* The most ancient Edda was compiled by Soemund Sigfusson, surnamed the Learned, who was born in Iceland about the year 1057. This was abridged, and rendered more easy and intelligible, about one hundred and twenty years afterwards, by Snorro Sturleson, who was supreme judge of Iceland in the years 1215 and 1222; and it was published in the form of a dialogue. The latter added also the second part in the form of a dialogue, being a detail of different events transacted amongst the divinities. The only three pieces which are known to remain of the more ancient Edda of Soemund are, the Volupsa, the Havamaal, and the Runic chapter. The Volupsa, or prophecy of Vola, or Fola, appears to be the text on which the Edda is the comment. It contains, in two or three hundred lines, the whole system of mythology disclosed in the Edda, and may be compared to the Sibylline verses, on account of its laconic yet bold style, and its imagery and obscurity. It is professedly a revelation of the decrees of the father of nature, and the actions and operations of the gods. It describes the chaos, the formation of the world with its various inhabitants, the functions of the gods, their most signal adventures, their quarrels with Loke their great adversary, and the vengeance that ensued; and it concludes with a long description of the final state of the universe, its dissolution and conflagration, the battle of the inferior deities and the evil beings, the renovation of the world, the happy lot of the good, and the punishment of the wicked. The Havamaal, or Sublime Discourse, is attributed to the god Odin, or Woden, who is supposed to have given these precepts of wisdom to mankind; it is comprised in about a hundred and twenty stanzas, and resembles the book of Proverbs. Mr Mallet has given several extracts of this treatise on the Scandinavian ethics. The Runic chapter contains a short system of ancient magic, especially of the enchantments wrought by the operation of Runic characters, of which a specimen is also given. A manuscript copy of the Edda of Snorro is preserved in the library of the university of Upsal; the first part of it was published with a Swedish and Latin version by M. Goranson. The Latin version is printed as a supplement to Mallet's Northern Antiquities. The first edition of the Edda was published by Resenius, professor at Copenhagen, in the year 1665, in a large quarto volume, containing the text of the Edda, a Latin translation by an Icelandic priest, a Danish version, and various readings from different manuscripts. Mallet has also given an English translation of the first part, accompanied with remarks; from which we learn, that the Edda teaches the doctrine of the Supreme, called the Universal Father, and Odin, who lives for ever, governs all his kingdom, and directs the great things as well as the small; who formed the heaven, earth, and air; who made man, and gave him a spirit or soul, which will live after the body shall have mouldered away: then all the just shall dwell with him in a place called Gimle or Vingolf, the palace of friendship; but wicked men shall go to Hela, or death, and thence to Niflheim, or the abode of the wicked, which is below in the ninth world. It inculcates also the belief of several inferior gods and goddesses, the chief of whom is Frigga or Frea, that is, *lady*, meaning thereby the earth, who was the spouse of Odin or the Supreme God; and hence we may infer that, according to the opinion of these ancient philosophers, this Odin was the active principle or soul of the world, which uniting itself with matter, had thereby put it in a condition to produce the intelligences or inferior gods, and men, with all other creatures. The Edda likewise teaches the existence of an evil being called Loke, the calumniator of the gods, and the artificer of fraud, who surpasses all other beings in cunning and perfidy. It teaches the creation of all things out of an abyss or chaos; the final destruction of the world by fire; the absorption of the inferior divinities, both good and bad, into the bosom of the grand divinity, from whom all things proceeded, as emanations of his essence, and who will survive all things; and, lastly, the renovation of the earth in an improved state.

EDDREDSI, an island in the Red Sea, six miles from the coast of Arabia. Long. 41. 33. E. Lat. 17. 10. N.

EDEGHERRY, a town of Hindustan, in the Carnatic, 144 miles north-west from Madras. Long. 79. 42. E. Lat. 14. 51. N.

EDEN, the name of a country, with a garden, in which the progenitors of mankind were settled by God himself. The term denotes pleasure or delight. It would be endless to recount the several opinions which have been entertained concerning its situation, some of them very wild and extravagant. The garden was also called Paradise; a term of Persic original, denoting a garden. See PARADISE.

EDER, a town of Hindustan, possessed by independent chiefs, in the province of Gujerat, fifty-three miles north-north-east from Ahmedabad. Long. 73. 3. E. Lat. 23. 35. N.

EDESSA, also called ÆGÆ, a city of Macedonia, in the district of Emathia, twenty-eight miles west of Pella, which is celebrated in the ancient history of this kingdom as being the point from which the powerful family of the Temenidæ commenced their career of conquest, and from which they did not desist till they had subdued the whole of the neighbouring country. (Herodot. viii. 137, 138; Justin. vii. 1.) It continued long the royal residence; and even after it had ceased to be so, it still remained the burial place of the race of Temenus, and, as Diodorus says, the *hearth* of their empire. Here were interred Philip and Eurydice, king and queen of Macedonia; and it was intended that the body of Alexander, which was interred at Memphis in Egypt, should be placed in these vaults. (Diodor. xix. 52; Pausan. i. 6.) It was here that Philip was assassinated by Pausanias, at the marriage of his daughter Cleopatra with Alexander king of Epirus. (Diodor. xvi. 92.)

It is supposed to be the modern city of Vodina, on the river Vistritza, where Dr Clarke says there are sepulchres cut in the rock, which the superstitious inhabitants have never plundered, because they are afraid to go near them.

EDGWARE, a town of the county of Middlesex, partly in the parish of that name, and partly in the parish of Whitchurch or Little Stanmore, nine miles from London. Its chief importance is derived from being on the great road to St Albans and to Buckingham, a road constructed by the Romans, called the Watling Street. It formerly was remarkable for the splendid palace of the Duke of Chandos, which was one of the most highly finished and decorated of any of the noble edifices in England. This building has, however, been pulled down, and one of the wings converted into a dwelling for a family of respectability. The population of the parish amounted in 1801 to 412, in 1811 to 543, in 1821 to 551, and in 1831 to 591; but the parish does not include the western part of the town.

EDHILING, EDHILINGUS, an ancient appellation of the nobility among the Anglo-Saxons. Instead of *edhiling*, we sometimes meet with *atheling*, or *ætheling*; which appellation was likewise given to the king's son, and the presumptive heir of the crown.

EDICT, in matters of polity, an order or instrument, signed and sealed by a prince, to serve as a law to his subjects. We find frequent mention of the edicts of the prætor, or the ordinances of that officer, expounding the principles on which he was to administer the law.

EDINBURGH.

Situation.

EDINBURGH, a city, the capital of Scotland, and chief town of Mid-Lothian, or Edinburghshire, is situated within two miles of the south shore of the Frith of Forth, at the distance of about 392 miles north from London, in 55. 57. 20. north latitude, and 3. 10. 30. west longitude. The situation of this ancient city is exceedingly romantic. It occupies a congeries of hills and elevated grounds, rising gradually from the shore of the Forth, and attaining in some parts to a considerable height above the level of the sea. The central elevation, which has been compared to nothing so aptly as a wedge lying flat upon the ground, is terminated at its highest or western extremity by a mass of rock, seven acres in superficies at top, and about two hundred and fifty feet above the surrounding country; on which stands Edinburgh Castle, the nucleus of the city. From the castle, along the descending slope towards the east, and for a mile in length, the original, or, as it is now called, Old Town, was built in the shape of a spacious street. In latter times, the city, by means of bridges, was extended to the grounds on the south and north.

Origin and name.

The etymology of the name Edinburgh is obscurely but certainly found in the history of its origin. Subsequently to the year 449, or the era of Anglo-Saxon dominion in Lothian, the Castle became the occasional residence of the chiefs of the Northumbrian dynasty; and from Edwin, the potent king of the territory, the appellation *Edwin's burgh* was introduced. At a period coeval with or preceding the era of Edwin, the name applied to the fort was *Mai-din* in British, or *Magh-dun* in Gaelic, which may either signify the fortified mount in the plain, or the good fort; but when the English language came into use, some busy fancies conceived that *Mai-din* was the same as *Maiden*, and hence arose the title which it obtains in old writings, of *Castrum Puellarum*, the castle of maidens, and the fable that it had been the residence of the daughters of the British kings. The origin of Edinburgh can now with tolerable accuracy be traced to the beginning of the seventh century, or the era of Edwin, from which period it gradually though slowly increased in size. In the year 856 it is described as a considerable village; and, with the castle, it was often the object of contest in the wars which took place between its Anglo-Saxon possessors and the natives of Scotland. From the period of the cession of Lothian to the Scots, in 1020, the Castle continued to be the frequent residence of their monarchs; and here the widowed consort of Malcolm Ceanmore, the pious and worthy Margaret, died in the year 1093. In the reign of David I. the Castle continued a royal residence, and the town increased so much as to be considered one of the four chief burghs in the kingdom. Soon after his accession the munificent David founded the Abbey of Holyrood, on the plain at the eastern extremity of the rising ground on which Edinburgh was built. On the canons of this abbey he conferred the privilege of building a suburb westward from their church, along the ridge, in order to meet the burgh; and the new town thus reared by the monks received from them the name of *Canonsburgh*, or popularly *Canongate*, which title the eastern part of the old city still retains. For a considerable period after the reign of David, the houses of Edinburgh were all thatched with straw; but it nevertheless rose into importance, and in the twelfth century it was constituted a royal burgh by William I. surnamed the Lion.

The death of Alexander, king of Scotland, proved fatal to Edinburgh. In June 1291 the town and castle were surrendered to Edward I.; but in 1313 they were recovered by assault, under the conduct of Randolph earl of Moray, and the castle was destroyed. The English again took and repaired the castle under Edward III., who resided there and placed a strong garrison in it. In 1337 the castle, still in the custody of the English, was besieged by Sir Andrew Moray, the guardian of Scotland, though without success; and it was only by an ingenious stratagem, employed by Sir William Douglas, in 1361, that the fortress was secured by the Scottish patriots.

From the era of the murder of James I. at Perth, in 1436–37, the origin of Edinburgh as a national capital may be dated. Neither Perth nor Scone, Stirling nor Dunfermline, being able to secure royalty against the designs of the nobility, Edinburgh and its castle were therefore selected as the only places of safety for the royal household and the functionaries of government. The infant sovereign was crowned in the chapel of Holyrood, in which sat the first parliament of his reign. James II. was particularly attached to Edinburgh, and bestowed on it a variety of grants as to the holding of fairs and markets, the levying of customs, and also rights to property. Besides, in 1450, he conferred upon the city the pre-eminent privilege of erecting walls and bulwarks for its defence. Throughout the turbulent reign of James III. Edinburgh was the seat of the court and regular parliament; and this king conferred additional immunities upon the city, especially one assigning sites for certain markets, which to the present day partly continue in the places thus fixed upon. On account of the loyalty of the people in assisting him against Edward IV. he moreover granted the inhabitants a banner, with power to display the same in defence of their king, their country, and their own rights. This flag, which is still esteemed a sort of palladium of the city, is called from its colour the *Blue Blanket*, and remains in the custody of the convener of the trades. In 1497 Edinburgh being visited by a loathsome distemper, imported from abroad, the king by a proclamation ordered the magistracy to put out of the town all infected persons, who, in order to free the city, were transported by boats to the island of Inchkeith in the Frith of Forth, which thus served as a lazar-house for the time. James III., in his latter years, made Edinburgh Castle the repository of his treasure, valuable effects, and ordnance. In 1488, when this prince was murdered near Stirling, the whole fell into the hands of his rebellious subjects.

The first parliament of James IV. was held at Edinburgh; and in 1503, on the marriage of this prince with Margaret, the eldest daughter of Henry VII. of England, it was the scene of a gorgeous royal pageant, which is fully recounted by the historians of the time. In 1508 the king empowered the town to let the grounds of the Boroughmuir on the south; but the citizens were no sooner in possession of this grant, than they set about clearing the ground of its wood, and so many trees were cut down that they could not be disposed of; wherefore the magistrates enacted, that whosoever should buy as much as would form a new front to a house, might extend the same seven feet farther into the street. In consequence of this preposterous edict, Edinburgh was in a short time filled with houses of wood instead of stone, and the principal street was reduced fourteen feet in breadth. The year 1513 was the epoch of a dreadful plague, and also of the great national calamity, the defeat at Flodden. With James perished the magistrates and many of the burgesses; the privy council removed to Stirling for safety; the walls of the city were greatly extended to the south, and better fortified; and at the same time, 1514, the corporation of the burgh raised the civic military corps called the town guard, which remained in force till the year 1817.

Throughout the minority of James V. the capital was the constant scene of tumults, especially one between the Hamiltons or Arran's party, and the Douglasses or party of Angus, which is known in history by the name of *Clear the Causeway*. May 1532 is the era of the greatest event in the annals of the Scottish metropolis. This was the establishment of the College of Justice, or series of supreme courts and their functionaries. The city now became a place of resort from all parts of the kingdom; and the magistrates for the first time had the High Street repaired and paved, and gave orders to the citizens to light it. In 1538 the town was the scene of rejoicings, on the entrance into the city of James, with his wife Mary of Guise.

In 1544 the regency having refused to ally the young Queen Mary to the son of Henry VIII., an English fleet and army were sent to ravage Scotland; and in prosecution of this object the Earl of Hertford landed with a force near Leith, and set fire to the city in several places. In 1548 Edinburgh was garrisoned by French troops under D'Esse, who prevented the English from committing any further serious damage.

Disturbances consequent on the change of religion in Scotland broke out in 1556, at which time a concourse of people assembled to protect John Knox from the violence of the ecclesiastical judicatory. During the struggle which ensued in effecting the reformation, Edinburgh formed the chief position of the reformers, as Leith was of the French and Catholic party. By the assistance of a Protestant army sent by Queen Elizabeth, the reformers were finally triumphant, and the first assembly of the reformed kirk met at Edinburgh on the 15th of January 1560.

A new object of excitement soon appeared in the person of Mary, the young queen of Scots, who on the 9th of August 1561 arrived at Leith from France. On the 1st of September she made her public entry into the city. Darnley was proclaimed king at the market-cross in July 1565, and next morning was married to the queen in the chapel of Holyrood. In June following the queen was delivered of a son, afterwards James VI.; and in February 1567 Darnley was blown up by gunpowder in a house at the Kirk of the Field, on the site of which the college now stands. Mary's marriage with Bothwell occasioned fresh disturbances in Edinburgh; and during the period of the irregular warfare which ensued between the king's and queen's parties, the city suffered very severely. At length the young king himself entered upon public life, and on the 17th of October 1579 arrived in the metropolis with a cavalcade of two thousand horse, and held his first parliament in person. In the year following, the Earl of Morton was beheaded in Edinburgh, by an instrument called the *Maiden*, which he had himself introduced, and which is now preserved in the Museum of the Society of Antiquaries. The character of the city was about this period greatly improved by the erection of the college, which was commenced in 1581, and its first professor appointed in 1583. The infant institution was warmly patronized by King James, who, on the occasion of a temporary visit which he made to Scotland in 1617, desired that it should thenceforth be called King James' College. In 1585–86 the city was visited by the plague, and suffered severely from that affliction. In 1591 the city was alarmed by an attempt of the Earl of Bothwell to seize upon the person of the king in Holyrood Palace. The attempt, however, was defeated by the promptitude and vigour of the citizens. Bothwell himself escaped, but eight of his followers were taken and put to death on the following day. In 1596 the clergy and citizens united in tumultuary resistance to an attempt made by the king to control the language of the pulpit. Unable to subdue or restrain the insurrectionary spirit which he had excited, James withdrew from the town, and ordered all the public courts to be removed from it. A reconciliation, however, soon afterwards took place, and the offended monarch returned peaceably to his capital. In 1599 the first regular dramatists appeared in Edinburgh. They were from England, and there is some reason to suppose that the immortal Shakspeare was amongst the number.

Three years after this the regal dignity of Scotland became extinct, or rather merged in that of England. On the 24th of March 1603, James was called to the throne of the sister kingdom. Two days before his departure, he addressed the citizens in St Giles' Church, promising them a continuation of his countenance, and expressing the regret which he felt at leaving them. Amongst the marks of royal favour with which James visited Scotland after his accession to the throne of England, was his empowering the magistrates of Edinburgh, in 1609, to have a sword of state carried before them, and to wear gowns; this, it is believed, being the earliest appearance of magisterial robes in Scotland. In 1617 James paid a long-promised visit to his native country. He entered Edinburgh by the West Port, and was conducted through the city with great pomp, and every demonstration of rejoicing. On the 28th of June he convened his twenty-second parliament at Edinburgh. In this assembly there were several remarkable acts passed, and amongst these one for the restitution of archbishops, bishops, and chapters. Four years after this, namely, in 1621, an act of the estates and town council was passed for coping houses with lead, slates, or tiles, instead of thatch, which had hitherto been the covering commonly employed. In the same year water was introduced by pipes into the city; and three new bells were imported from Campvere in Holland, two for St Giles' Church, and one for the Netherbow Port.

Edinburgh seems to have enjoyed uninterrupted tranquillity during the remaining period of King James's reign. When he died, in 1625, the ministers of the city eulogised him as the "most religious and peaceable prince that ever was in this unworthy world." After the accession of Charles to the throne, which was proclaimed at the cross by the officers of state, a convention was held; and the town council, in consequence of certain ships of war being wanted, and forts for securing the coasts, not only agreed to advance the assessment when called upon, but also to contribute towards the maintenance of 10,000 men. Some time afterwards, a subsidy for four years having, at the king's desire, been granted by parliament, the inhabitants of Edinburgh generously advanced at once their quota, amounting to L.40,000 Scots. For these acts of kindness his majesty expressed his gratitude, by sending a sword and gown to be worn by the provost in the manner appointed by his father. Like his father, too, Charles resolved to visit his native country, and though prevented for some years from fulfilling his design, he at last accomplished it in 1633. He was received by the inhabitants with much pomp, and the celebrated Drummond of Hawthornden was appointed to address him on his arrival, which he did with all the characteristic poetical embellishment peculiar to the times. On the 18th of June, Charles was crowned in the Abbey Church of Holyrood, and on the 20th he assembled his first Scottish parliament in the Tolbooth. During his residence in the city on this occasion, Charles erected the bishopric of Edinburgh, a measure which was by no means popular, and gave rise throughout the country to a series of civil disturbances, the principal focus of which seems to have been Edinburgh. During the civil war in 1640, the magistrates fortified the town against the castle, and disciplined the citizens. The governor, on perceiving these demonstrations of hostility, fired upon the city; but being soon afterwards invested by General Leslie, he was compelled to surrender from want of provisions.

Charles visited the city a second time in 1641, and was received and entertained by the magistrates with the utmost deference and respect. A parliament met on the 15th of July, the result of whose proceedings was an entire change in the government, Charles retaining only the name of king, and the kingdom the appearance only of a monarchy. He agreed to an act of oblivion, by which his opponents were pardoned at the expense of his friends; and after a residence of four months in the northern metropolis, he returned to London, having entrusted his Scottish affairs to a committee of the estates. Two years after this, in the month of July, the Solemn League and Covenant for the extirpation of prelacy was signed in the High Church; and shortly afterwards the city raised and supported a regiment of twelve hundred men, to assist the English parliamentary forces against Charles, at a cost of L.60,000 Scottish money. For this and several other acts of hostility to the king, the town was in 1645 threatened with a visit from the Marquis of Montrose; but it was saved from this disaster by the presence of another. This was the plague, which committed great ravages amongst its population. It was, however, the last visit which this dreadful scourge paid to the metropolis. Shortly after this (such were the changes of these eventful times), the city borrowed L.40,000 Scots to raise troops for the national engagement in favour of Charles. This debt they afterwards refused to pay, on the plea that it was contracted in an unlawful cause. The impartial justice of Cromwell, however, subsequently compelled them in 1652 to refund the money. In May 1650 the Marquis of Montrose was conveyed a prisoner into Edinburgh. Three days afterwards he was brought to trial, condemned to death, and suffered on a gallows erected at the cross. Two months subsequently Charles II. was proclaimed on the same spot; and in the end of September following, the town was in the possession of Cromwell. On this occasion the magistrates fled to Stirling, then the head-quarters of the king's forces. The town was thus left without any other civic rulers than that of a body of thirty citizens, chosen by the inhabitants to discharge in part the functions of the magistracy, who absented themselves from the 2d of September to the 5th of December 1651. About this period the town council granted liberty to one Adam Woodcock to establish a stage-coach between Edinburgh and Leith; which is amongst the first notices of a public conveyance of the kind in Scotland, and on that account sufficiently remarkable.

On the 11th of May 1660, the magistrates sent the town-clerk to Charles, who was at Breda, expressing their concurrence in his meditated restoration, already agreed to by both houses of parliament in England, and their joy at the prospect of such an event. Their messenger "had a most gracious acceptance;" and, in the name of the burgh, presented "a poor myte of L.1000, which he did graciously accept, as though it had been a greater business." The feelings of delight which the arrival of the king in England excited in Edinburgh, were expressed in the customary mode of costly feasting, a sumptuous banquet having been served up by the town council at the cross. This attachment on the part of the citizens was ill requited by Charles, who, in settling the affairs of the kingdom, re-established episcopacy in Scotland, in opposition to the oath and obligation of honour by which he was bound. It is not surprising, therefore, that the Scottish people, so attached to presbyterianism, should have expressed their indignation at his conduct in the most open manner. But when the liberty of the press, and freedom in matters of religion, were in consequence also speedily infringed upon, the whole country rose in arms, particularly the western counties. The attempt, however, which was made upon the life of Archbishop Sharp in the streets of Edinburgh led that prelate to advise those milder measures which were soon afterwards adopted by government. In 1679, James, then duke of York, came to reside in Edinburgh, and took up his abode in the Palace of Holyrood, where he remained till May 1682. During this period he rendered himself extremely odious by his opposition to the Covenanters, and by his attempting the revival of the drama, and encouraging other amusements to which the people were exceedingly averse.

Two years after this, the magistrates set up for the first time a regular state carriage; and were so much pleased with the accommodation and conveniency of this novelty, that they ordered two coaches from London for their own especial use, with the addition of four horses. On the demise of Charles II. in 1685, the town council erected an equestrian statue to him in the Parliament Square, as a proof of their gratitude to and affection for that monarch. Soon after James' accession, the unfortunate Earl of Argyll was brought a prisoner into Edinburgh; and after being ignominiously paraded through the streets, his head was struck off by the Maiden, this being the last time, it is believed, that the instrument was employed. After a series of disturbances and tumultuary proceedings, occasioned by the attempts of James VII. to restore the Roman Catholic religion, a convention of estates was held at Edinburgh, in which it was declared that James had forfeited the crown; a resolution which was followed in March 1689 by an offer thereof to William and Mary.

The next epoch in the history of Edinburgh is formed by the celebrated Darien expedition in 1696. The intervening period is not without interest, but it exhibits no event of any importance in relation to the city. The occurrences during that time were wholly of a national character, and are therefore more properly to be looked for in the history of the kingdom. In the famous bubble alluded to, Edinburgh was deeply interested, and was full of the high anticipations which this speculation had diffused throughout Scotland. About L.400,000 sterling were subscribed in the country. Six ships of considerable force and burthen, and laden with various commodities, sailed from the Frith of Forth; and in 1699, when intelligence arrived of the settlement being formed, the rejoicings in Edinburgh were unbounded. On the other hand, the disappointment excited on learning in the following year of its failure, filled the streets for several days with tumult and riot; and the city altogether presented such a scene of lawless anarchy, that the commissioner and officers of state deemed it necessary, for their personal safety, to retire until the popular fury had somewhat abated.

In 1702 a similar commotion was excited, from an apprehension on the part of the populace that one Captain Green, and his accomplices, four in number, who had been condemned for piracy and murder on the high seas, were, through the connivance of the authorities, to be permitted to escape the consummation of their sentence. The Lord Chancellor, in passing from the privy council in his coach, was attacked at the Tron Church, the glasses were broken, and he himself was dragged from the carriage. He was rescued by some of his friends; but it was found necessary to sacrifice the seamen to the resentment of the populace. The following year was distinguished by its presenting the last exhibition of the ancient Scottish national pageant called the Riding of the Parliament. This parting show took place on the 6th of May 1703. In 1704 the inhabitants of Edinburgh were gratified by a ceremony quite in accordance with the spirit of the age. By an act of the privy council, a large quantity of vestments, beads, chalices, crucifixes, and other appurtenances of Catholic worship, were brought to the cross, and there publicly burnt before the eyes of a delighted populace.

The tumults to which the city had been so frequently subject were revived in 1707, on the occasion of the proposed union of the kingdoms. This, as is well known, was at first an exceedingly unpopular measure in Scotland; and the consequence was a series of the most violent and outrageous proceedings on the part of the mob, in order to intimidate those members of the Scottish parliament who were favourable to the obnoxious project. The deed, however, was finally accomplished, though not without great danger to the lives of its most active promoters. A small summer house in the Regent Murray's garden is still pointed out as the place where the last signatures were attached to the document which terminated the independence of Scotland as a separate kingdom.

In the civil war of 1715 Edinburgh was little further involved than from the circumstance of an unsuccessful attempt made by the Jacobites to surprise the Castle. About this period the provost received a regular salary of L.300 per annum in order to defray his expenses; and in 1718 the scheme which had for some time been framed of extending the pier and building docks at Leith was in part executed; the town's debts, which even then amounted to L.25,000, being thereby, in the space of five years, nearly doubled.

The next occurrence of any importance in the annals of the city, was the celebrated tumult designated the Porteous Mob, which took place in September 1736. The accounts of this remarkable affair are so numerous, so easily accessible, and withal in general so full, that it is deemed unnecessary to give more than a mere outline in this place. Porteous, whose name distinguishes the transaction, was captain of the city guard. At the execution of a criminal of the name of Wilson, whose fate had excited an extraordinary sympathy, Porteous, dreading a rescue by the mob, who suddenly became tumultuary, ordered the guard to fire on them. Six people were killed by the discharge, and eleven wounded. For this Porteous was tried and condemned to death; but he was afterwards reprieved by Queen Caroline, then regent. Resolved however that he should not thus escape the fate which they conceived he merited, the mob, on the evening of the day previous to that on which he was to have been executed, broke into the jail in which he was confined, and having dragged him out, led him to the Grassmarket, the usual place of execution at that period, and there hanged him by torch light on a dyer's pole.

On the 17th September 1745 Edinburgh was taken possession of by the rebels under Prince Charles Edward. A party of the Highlanders secured the Netherbow port, and thus made themselves masters of the city. The main body of the rebel army arrived shortly afterwards at the King's Park, headed by the Chevalier in person, who took up his residence in Holyrood, where he held open court, and was visited by great numbers of the inhabitants. The city remained on this occasion in the hands of the rebels till the 31st of October, when, finding it impossible to reduce the castle, they proceeded on their march towards England.

The public transactions of an historical nature which occurred in the metropolis after these events, are not, except in a few instances, such as to require a particular description. On the 2d of February 1779, an infuriated mob, under the influence of religious fanaticism, burnt one Roman Catholic chapel and plundered another. Twelve years later, on the outbreaking of the revolution in France, a considerable body of the inhabitants manifested their admiration of the new political principles which were then brought so prominently forward, by forming themselves into associations for supporting the cause of political regeneration. These societies, the members of which received the appellation of Friends of the People, at length drew down upon them the notice and vengeance of government. Several persons accused of having been concerned in spreading sedition, and engaged in treasonable practices, were arrested and brought to trial. One of them named Watt, was condemned and beheaded, whilst others were transported. Subsequently, during the war with France, the citizens showed great zeal in support of the government, by forming themselves into regiments of volunteers, consisting of yeomanry, artillery, and several corps of infantry. On the last night of the year 1812, being the season devoted to innocent festivity, the streets of Edinburgh were disgraced by a series of riots, outrages, and robberies, hitherto unparalleled. During almost the whole night, after eleven o'clock, a gang, principally composed of young men, armed with bludgeons and other weapons, infested some of the principal streets of the metropolis, and knocked down, robbed, and otherwise wantonly maltreated almost every person who had the misfortune to fall in their way. In the dreadful tumult and scuffles which ensued, one officer of police was killed and many persons dangerously wounded, some of whom died in consequence, whilst a great number received severe contusions. Several rioters were seized, and being brought to trial, three were condemned and hanged, whilst some others were transported. This fearful outbreaking of juvenile delinquency led to the adoption of several beneficial plans for the better instruction of the lower classes, the benefits of which still continue to be felt.

The most remarkable event in which Edinburgh was more particularly concerned since that period was the visit of George IV. to Scotland in 1822, when he spent upwards of a fortnight in the metropolis, inspecting its public institutions, and receiving the congratulations of his Scottish subjects. Being the first crowned head that had entered Edinburgh since Charles II. in the year 1650, his late majesty's visit caused the greatest excitement throughout the country, and produced such an influx of people from the surrounding counties, particularly from the west and north, as never before perhaps took place in Edinburgh. His majesty arrived in Leith Roads on the 14th of August, and landed on the 15th, on which occasion he made a grand progress from Leith through several of the streets of the New Town to the Palace of Holyrood, and thence drove to the Duke of Buccleuch's house at Dalkeith, where he resided during his stay in Scotland. On the 17th he held a levee in Holyrood Palace, and on the 19th received the addresses of the commission of the General Assembly of the Church of Scotland. Next day he held a drawing-room, and on the 22d he went in procession from Holyrood House to the Castle. On the 23d he reviewed a body of cavalry on Portobello Sands, and on the same evening attended a ball given in honour of the royal visit by the peers of Scotland. On the 24th his majesty presided at a banquet given by the civic authorities, and on this occasion conferred on Sir William Arbuthnot, then Lord Provost, the honour of baronetcy. On the 26th his majesty attended a ball given by the Caledonian Hunt; on the evening of the 27th he appeared at the theatre; and on the 29th, after a visit at Hopetoun House, he embarked at Port Edgar, near Queensferry, on his return to England.

In 1824 the city suffered from a series of conflagrations of a most destructive and appalling description. The first of these commenced on the 24th of June, when some of the private dwellings in the Parliament Square, with a part of the High Street, and several closes, were consumed. The second and the most extensive began on the evening of the 15th November, and continued for three days, destroying an immense number of houses, chiefly between the High Street and Cowgate, also several fronting the High Street at the Cross, another portion of the Parliament Square, and likewise the spire of the Tron church, which had accidentally caught fire from the flying brands.

In no part of the united kingdom was the passing of the reform bill more strenuously insisted upon, or received, when framed into a law, with more heartfelt demonstrations of joy, than it was by the citizens of Edinburgh. The first election of members of parliament under that act took place at the cross on the 21st of December 1832; and never, except perhaps during the visit of George IV. was such a multitude of people collected upon its streets.

Edinburgh is surrounded on all sides, excepting on the north, where the ground slopes gently towards the Frith of Forth, by lofty hills. On the east, in the immediate vicinity of the city, are the abrupt and rocky elevations of Arthur's Seat, Salisbury Crags, and the Calton Hill, the first of which rises to the height of 800 feet above the level of the sea. On the south are the Braid and Pentland Hills, and on the west the hill of Corstorphine. Salisbury Crags form a continued range of naked and perpendicular cliffs, which rise like a mural crown from the summit of the hill, and at a distance have a singularly wild and romantic appearance, the interest of which is heightened by the contrast of the splendid city over which they tower majestically. The town stands on high and uneven ground, being built on three eminences, which run parallel to one another from east to west. The most elevated of these, on which the city was originally built, is terminated abruptly on the west by a precipitous rock surmounted by the Castle, whilst to the east it gradually inclines to the plain from which rises the lofty elevation of Arthur's Seat. The valley to the north of this ridge, which was formerly filled with water, has been of late years drained, and is now laid out in public gardens. It still retains, however, its original name of the North Loch.

Rise and progress of the city.

Till the middle of the eighteenth century, Edinburgh continued to occupy little more than the same space of ground which it had covered in the reigns of James III. and James IV.; namely, the ridge between the Castle on the west and Holyrood House on the east, with the hollow called the Cowgate on the south, and part of the rising ground beyond. In a great proportion of this Old Town the buildings are crowded and irregular, and the houses in some parts rise to the unusual height of eleven stories. The principal, or High Street, which is somewhat more than a mile in length, and is in some parts ninety feet in breadth, occupies the centre of the ridge, and extends, under different designations, nearly in a straight line from the Castle on the western extremity to the Palace of Holyrood on the eastern. Both sides of the ridge occupied by this street are covered with buildings crowded together in the closest array, and descending from the High Street, chiefly in narrow lanes, or closes as they are termed, which are seldom broader than six feet, and which, consisting of high houses on either side, are inhabited by numerous families, with little regard either to health or cleanliness. A proposal in the reign of Charles II. to extend the town over the lands to the north, beyond the hollow called the North Loch, having been frustrated, nothing was done till 1751, when an old building having fallen, by which one person was killed, a strong feeling regarding the inconvenience and decayed condition of the houses began to be expressed. The first decided step towards extending the city was taken by Provost Drummond, on the 21st of October 1763, when he laid the foundation-stone of what is now styled the North Bridge, in order to connect the town with the properties on the north. This edifice consists of three great central arches, each seventy-two feet in width and sixty-eight in height, with small side arches, making the total length 310 feet. In 1767, whilst this work was proceeding, an act for extending the *royalty* was obtained; and a plan for the New Town being then formed by Mr Craig, architect, the foundation of the first house was laid on the 20th of October the same year. By this plan the chief streets of the New Town of Edinburgh were disposed in three parallel lines from east to west; that on the south side, formed like a terrace, and facing the Old Town, being called Princes Street; a similar street facing the north, called Queen Street; and the third, which was named George Street, running up the centre. An elegant square at the west end of George Street, styled Charlotte Square, corresponded to another at its eastern extremity, designated St Andrew Square. Between Princes Street and George Street a narrow street of inferior houses runs along the whole length, and a street of nearly the same appearance is situated between Queen Street and George Street. Seven cross streets, namely, St Andrew, St David, Hanover, Frederick, Castle, Charlotte, and Hope Streets, intersecting these parallel thoroughfares at right angles from south to north, completed the plan. Coeval with the erection of these splendid streets and squares, a lofty street was opened from the extremity of the North Bridge and Princes Street, towards Leith Walk, or main road to Leith, opening an excellent communication with that sea-port. The whole of the new edifices according to Mr Craig's plan were completed about the year 1815, but the greater part much earlier. Only one serious error was committed by the local authorities in connection with the building of the New Town. This was the formation of a huge mass of earth called the Earthen Mound, which was laid down in the valley of the North Loch, parallel to the North Bridge, and calculated to serve the purpose of a second bridge. It was begun about 1781, out of the accumulation of the rubbish from the excavations of the New Town, and has been recently completed. It is computed to contain upwards of two millions of cart loads, and now serves as a thoroughfare from Hanover Street to the upper part of the Old Town.

Such was the success attending the building of the New Town, that in time a second extension of the same nature was projected, still farther towards the north, beyond an open area in front of Queen Street. The design of this second town intimately resembled that of its predecessor, consisting of a terrace in front and rear, a large central street, with two intermediate narrow ones, and cross streets in continuation of those in the former New Town. This vast and splendid addition to Edinburgh was commenced in 1801, and was nearly finished in the year 1826. Its central street is entitled Great King Street, and, as in the case of George Street, it is terminated by large open areas: one of these, of an oblong form, is styled Drummond Place; whilst the other, of a circular shape, is called the Royal Circus. Since this portion of the New Town was completed, another extension, still farther towards the north, has been projected, and is now partially built; and between the new streets in this quarter and the sea, a distance of about a mile and a half, are now built a number of isolated villas and ranges of houses, of a similarly elegant style of architecture.

About the time when the second New Town approached its completion, a series of superb edifices began to be erected on its north-western confines, between Charlotte Square and the Water of Leith, on the property of the Earl of Moray. This magnificent part of Edinburgh was erected during the years 1823, 1824, and 1825. An open space called Moray Place forms the chief cluster of buildings, and is considered as the most superb part of the modern extension of the metropolis. To the westward of Charlotte Square and Princes Street another series of beautiful streets and crescents have been erected, chiefly on the lands of Coates. As it is by a road through these new streets that persons from the west of Scotland enter the town, the appearance of so many structures on a scale of uniform splendour almost unrivalled in Britain, seldom fails to excite feelings of delight and admiration. This quarter of the town has latterly been considerably improved by the erection of a magnificent bridge of four arches, stretching across the deep dell or ravine at the bottom of which flows the Water of Leith. This bridge was completed in 1832, and will henceforth serve as the principal entrance to Edinburgh from the north.

The extension of the New Town to the north and west absorbed public attention till about the year 1813, when the idea was started of opening an entrance from the east. The foundation-stone of a bridge to form a connection with the Calton Hill, styled Regent Bridge, was laid in September 1815, and the work was completed in 1819. The arch of this structure is fifty feet wide, by about the same in height. On the top of the ledges of the bridge are arches and ornamental pillars of the Corinthian order, which on either side are connected with the houses in the line of street formed at the same time. The street, or

Waterloo Place as it has been designated, is composed of very superb houses of four stories, and each is terminated at Princes Street by a pediment and pillars above the lower story. From Waterloo Place, the new road by which most of the vehicles and passengers from the east enter the city, proceeds by a sweep round the southern face of the Calton Hill. The entrance by this thoroughfare is not less commanding and beautiful than that by the west; and the semicircular range of houses forming the Royal and Regent Terraces, lately erected on the slope of the hill, have a very striking effect. From the northern and eastern base of the hill towards Leith, the rudiments of another New Town were simultaneously formed. At present (1833) only a few streets in this quarter have been completed, but these are on a scale not surpassed by many of the modern structures.

Some years prior to the foundation of the New Town, certain private proprietors began to build lines of houses, of a good style of architecture, on the grounds to the south of the Old Town, and in this way George Square, Argyle Square, and Brown Square were opened for the reception of the higher class of citizens. The erection of these and other edifices soon suggested the necessity of a proper communication between them and the High Street, on the plan of the North Bridge; and on the 1st of August 1785, the foundation-stone of a bridge crossing the Cowgate, styled the South Bridge, was laid, and the thoroughfare opened for passengers in March 1788. The South Bridge consists of twenty-two arches, all of which are concealed by the buildings along its sides, with the exception of one at the centre spanning the Cowgate. In later times the city has spread very considerably towards the south; and beyond the outskirts of the streets in this direction there have been erected towards Newington a variety of neat and beautiful villas, which form the residences generally of the more respectable mercantile classes. From the period of the erection of the South Bridge in the year 1788, no further improvements took place in this direction, till after the opening of the Union Canal. The formation of this canal, to serve as a water communication with Glasgow, by joining the Forth and Clyde Canal, took place in virtue of an act of parliament procured in 1817 by a joint-stock company. Its eastern termination is about half a mile south-west from the Castle. Here the place of shipment, called Port Hopetoun, has been greatly improved by the erection of various new streets, one of which communicates directly with the west end of Princes Street or the New Town. In order to form an equally direct line of communication with the Old Town, and, generally speaking, that the High Street might be more thrown open to an approach from the southern districts, an act of parliament was procured by the inhabitants in 1827, vesting powers in certain individuals called Commissioners of Improvements, to open two lines of approach to the Old Town, one proceeding from the neighbourhood of Port Hopetoun on the south-west, and the other from the district on the south, adjacent to George Square and the open grounds or Meadow Walks in its vicinity. Both lines were calculated to render the destruction of many houses on the Castle Hill and in the Lawnmarket absolutely necessary, as well as to require bridges of an expensive nature; and the outlay for the whole was ordained by the same and by a subsequent act of parliament to be defrayed by assessments upon the inhabitants. These improvements are now (1833) in progress, and when finished will do much to renovate the more ancient part of the capital, as well as to form useful thoroughfares through the town.

At the present day the city extends about two miles in length and the same in breadth, and presents, when viewed from the Calton Hill, one of the most extraordinary panoramic scenes which can be conceived. On the right are the splendid lines of streets of the New Town, constructed of white sandstone, gradually spread out with a moderate descent towards the flat ornamental grounds adjacent to the sea. In front we have the vista of Princes Street, nearly a mile in length; and on the opposite side of the ravine of the North Loch, now disposed as pleasure-grounds, the huge unbroken line of tall structures forming the Old Town, terminated by the towers of the Castle. Beyond and towards the south, the town is seen to spread out in lines of streets and detached houses, till arrested by the fields and inclosures towards the Braid Hills, or on the east by the precipitous heights called Arthur's Seat and Salisbury Crags. The view from the Calton Hill in a northerly direction is also remarkably fine, comprehending a prospect of the whole Frith of Forth, and the hills of Fifeshire on its opposite shore.

We now proceed to notice Edinburgh in detail, commencing with a description of its more remarkable public edifices.

Public buildings and institutions.

The Castle, as has already been stated, owes its origin as a regular place of defence to the Anglo-Saxon dynasty, near the end of the fifth century; but its fortifications appear to be of comparatively modern date. The rock on which the fortress is situated rises to a height of three hundred feet, and is precipitous on all sides except the east, on which it is connected with the town by an open glacis or esplanade. The surface of the rock measures about seven acres, and is surmounted by battlements, lofty barracks, and other buildings. Amongst the buildings crowning the summit is that erected by Queen Mary as a palace, in a small apartment on the ground floor of which that princess was delivered of her son, James VI., on the 19th of June 1566. In the same part of the edifice is situated the crown room, where the regalia of Scotland were lodged in 1707, and found in 1818, after being lost sight of for upwards of one hundred years. These regalia consist of a crown, sceptre, sword of state, and lord treasurer's rod; the former is supposed to be even more ancient than the time of Robert Bruce, though it has undergone several changes since that period; the sword was a present from Pope Julius II. to James IV. The arsenal or storehouse of the Castle is capable of containing 30,000 stand of arms, and the whole buildings about 2000 men. In March 1829 an addition was made to the curiosities of the castle by the restoration of an ancient piece of ordnance called Mons Meg, which had been removed from the fortress and carried into England in 1754. This immense cannon, for it is of an unusual size, was fabricated in the year 1498, and is curious from its structure, being formed of bars bound together with rings. It was employed at the siege of Norham Castle, but was rent in 1682, when firing a salute in honour of James duke of York.

The charter of foundation of the Abbey of Holyrood is dated 1128. It was largely endowed by the founder David I., and was considered as one of the wealthiest ecclesiastical establishments in Scotland. In 1544 it was sacked, and in part destroyed, by the Earl of Hertford when he invaded Scotland; and again in 1547. The chapel attached to it was desecrated and dismantled by the mob in 1688; and in 1768 the roof fell in, and thus left it in the ruined condition in which it now stands. Within this chapel were interred, amongst other illustrious remains, those of Queen Magdalen and Darnley. The royal palace is contiguous. It is not known at what time a palace was first erected on this spot. The more ancient parts of that which is now in existence were built by James V.; but it has since undergone many changes, and little if any of the original building remains. In the time of Cromwell it was burnt by the soldiers of that usurper, and was rebuilt after the Restoration by Charles II. The architect on this occasion was Sir William Bruce, and the builder who carried his designs into execution was Robert Mylne. The edifice is of a quadrangular figure, with an open court in the centre, surrounded with piazzas. Amongst the curiosities exhibited in the Palace of Holyrood is the chamber of Queen Mary, in which may still be seen, though in a decayed state, the bed of that unfortunate princess. In a hall or gallery a hundred and fifty feet in length, twenty-seven and a half in breadth, and eighteen in height, and which is adorned with the portraits of a hundred and six Scottish monarchs, takes place the election of representative peers for Scotland. The most remarkable circumstance connected with Holyrood House is its privilege of affording a sanctuary to debtors. The limit of this privileged territory is marked in the direction of the town by a strand or gutter at the foot of the Canongate, and at the distance of about a hundred yards from the palace. Altogether the sanctuary describes a circle of about five miles, including Salisbury Crags and Arthur's Seat. The immunities of the sanctuary have existed since the date of the monastery. Considerable improvements were made on the exterior walls of the palace during 1832, and some years previously, at the expense of his majesty.

Edinburgh is now chiefly distinguished as a capital by being the seat of the Scottish supreme courts or College of Justice, which, as has already been mentioned, was constituted in 1532 by James V. This body consists of persons intimately connected with the various supreme courts, and comprehends the judges or senators, the faculty of advocates, writers to the signet, solicitors in the supreme courts, advocates' first clerks, clerks to the judges, extractors, keepers of the different departments, and, in a general sense, may be said to include the principal professional gentlemen in Edinburgh. This influential body at one time possessed some valuable privileges, the chief of which now remaining are exemptions from certain local taxes, and non-liability to be sued before any inferior civil court of record.

The principal court connected with the College of Justice is the Court of Session, or supreme civil court. This judicature possesses all those peculiar powers exercised in England by the Courts of Chancery, King's Bench, Common Pleas, Admiralty, and others, being a court both of law and of equity. The constitution of the court, during its continuance of three hundred years, has undergone many alterations, and is now established upon an improved plan, introduced by an act of parliament passed in 1830. There are thirteen judges, who are separated into the first and second divisions. In the former there are six lords, and in the latter seven. The presiding judge in the first division is the Lord President, and in the second division the Lord Justice Clerk, a title which he derives from being co-ordinately the presiding judge of the High Court of Justiciary. The two divisions form distinct courts, which, excepting on particular occasions, have no connection with each other. Popularly, they are each denominated the Inner House, from their meetings being held in inner apartments leading from the Outer House, or hall of the Parliament House. From the first division are detached two judges with the title of Lords Ordinary, and from the second there are detached three. Before one or other of these ordinaries all causes are brought in the first instance; and, in case of dissatisfaction with their judgments, the suits can be removed by appeal into the Inner House, but always to that division before whose ordinary the case was primarily brought. The office of Lord Ordinary on the Bills, which is successively discharged by the judges, is of great importance in a national sense, as, besides other duties, it includes that of supreme civil magistrate of the kingdom. Cases may be removed by appeal from the Court of Session to the House of Lords. The court has a winter term of four, and a summer term of two months.

Agreeably to certain acts of parliament, a civil jurisdiction, with the title of Jury Court, was instituted in Scotland, and subsisted under various modifications, between the years 1816 and 1830, when it ceased as a separate court. By the act 1 William IV. cap. 69, passed 23d July 1830, the benefit of jury trial in civil causes was united with the ordinary jurisdiction of the Court of Session. In virtue of this act, the lords president of the two divisions respectively try by jury all issues arising out of causes in these divisions, and otherwise discharge all duties previously assigned to the Lord Chief Commissioner of the Jury Court. In certain circumstances, the ordinary lords of session may also discharge the same duties, and the Lord Chief Commissioner is still qualified to act as a judge in such causes. The juries who are impannelled under this branch of the jurisdiction of the Court of Session are twelve in number, as in England, and must be unanimous in their verdicts or findings.

Every alternate Wednesday during terms, the Teind Court of Scotland, instituted in 1707, is held in Edinburgh, in the apartment of one of the divisions. The judges of the Court of Session are, by commission, judges also in this. It is the peculiar duty of the Teind Court to regulate the stipends of the clergy of the established church of Scotland, and other secular matters touching ecclesiastical polity. Nine judges form a quorum.

The High Court of Justiciary was instituted in 1672. It is composed of a president, styled the Lord Justice Clerk, and five other judges, who are at the same time lords of session. This supreme criminal court sits every Monday during term, and in the vacations of the Court of Session, the commissioners of justiciary proceed, in small detachments, upon appointed circuits.

The Commissary or Consistorial Court, the duties of which comprehended pleas relative to declarators of marriage and legitimacy, to divorce, adherence, and the like, was in 1830 amalgamated with the Court of Session. The head consistorial court of Scotland was thus almost entirely abolished. A certain number of commissaries, however, yet remain, whose duty consists in granting confirmation of testaments of persons dying abroad and leaving personal property in Scotland. They have also a special jurisdiction in the county of Edinburgh, the same as sheriffs in other counties.

The Dean of Guild Court consists of the Dean of Guild, Old Dean of Guild, and six guild councillors. The powers of this court were formerly far more extensive than they are at present, having relation to causes between merchant and mariner, as well as to those between merchant and merchant. The institution, however, of the Admiralty Court, by the act 1681, cap. 16, superseded its interference with maritime affairs. Even yet, the functions of the individual who is at the head of it do not seem to be very distinctly defined; but he is independent of the burgh or bailie court. The Dean of Guild is chosen yearly, and with his council has power to regulate the buildings within burgh, agreeably to law. He alone is competent to grant authority, by his warrants, or jedges as they are called, for pulling down or erecting houses; and he gives directions as to keeping buildings and streets in proper repair. The provost and bailies have no power to review the decrees of the Dean of Guild, redress being only competent in the Court of Session, as in the case of judgments by the bailie court. For more specific information, see GUILD.

The Court of Exchequer is now abolished as a separate judicature, its functions being included in those of the Court of Session. The only remaining branch of the Scottish Exchequer establishment now consists of a variety of officers for conducting the business connected with the different descriptions of revenue drawn from the country, which pass through this channel. Amongst these is an officer of the crown, with the title of King's Remembrancer for Scotland, whose duty it is to secure all fines payable to the king, all treasure found, and property falling to the crown as *ultimus hæres.*

The Lyon Court is now nearly extinct. The duties of the Lord Lyon, so named from the circumstance of the lion forming the armorial bearing of the kings of Scotland, are performed by two deputies. These duties consist in the ordering of proclamations, conferring armorial bearings, and superintending the management of state ceremonials and processions. He has besides a control over a large body of messengers at arms, and other officials, amongst whom are six heralds, and the same number of pursuivants. The fees payable at the lyon office for patents of arms are, for arms without supporters L.52. 10s., and with supporters L.84; but if the patent be granted as a *favour,* the price is L.115. 10s. The Lord Lyon receives a share of the fees to the amount of L.700 a year. Altogether his office is worth about L.1300 annually. It is enjoyed by the Earl of Kinnoull.

The Faculty of Advocates is an association of barristers entitled to plead before the supreme or any other courts of record. It consists at present of four hundred and thirty members, who are presided over by a Dean. All candidates for admission into this society must undergo an examination on the Roman and Scotch law, and every member on entering pays a fee of nearly L.300, one half of which goes to support the library belonging to the Faculty. The appointment of judges of the Court of Session, and the thirty-three sheriffships of Scotland, together with several other government offices and dignities, are filled up exclusively from this body. The Faculty, however, possesses no charter of incorporation.

The Society of Writers to the Signet is also an unincorporated body, consisting at present of nearly seven hundred members, qualified to conduct causes before the supreme courts, and possessing the sole right of passing papers or warrants under the signet or seal of his majesty, from which circumstance their professional name is derived. The principal and most lucrative branch of their professional employment is that of conveyancing. In order to promote the study of this important department of legal practice, they, many years ago, founded a lectureship, which was, in 1825, erected into a professorship in the University. In order to gain admission into this Society, an apprenticeship of five years is necessary. At entering into his indentures, the apprentice must show that he has attended a university for two years; and, during the course of his apprenticeship, he must attend the law classes in the University. A thorough examination on the principles of the law of Scotland, and the practice of conveyancing, takes place previously to admission into the Society. Its affairs are administered at stated meetings. It possesses an extensive and very valuable library; and most of the members are associated in supporting a fund for widows, which, by act of parliament, must amount to L.20,000 for every hundred members.

The Solicitors before the Supreme Courts form a body of attorneys incorporated in 1797. Its members amount to between one and two hundred. With the exception of the power of passing papers under the seal of his majesty, their privileges are nearly the same with those of the Writers to the Signet. They have also office-bearers, a hall of meeting, and a library.

Of the class of practitioners denominated Advocates' First Clerks, there are not a great number. They are entitled to act as attorneys in the Supreme Courts on undergoing the usual examinations, and paying certain fees. Every advocate has the privilege of appointing a clerk.

The edifice which has been appropriated since the Union as the place of meeting of the supreme courts, is the old Parliament House of Scotland, situated in the centre of the Old Town, and separated from the High Street by the cathedral of St Giles. This structure was erected between the years 1632 and 1640, at an expense of L.11,600 sterling to the civic corporation. In recent times, however, with the exception of the great hall, it has been almost totally renewed. It stands on the southern and western sides of the inclosure called the Parliament Square, a place formerly surrounded with the shops of tradesmen, but entirely remodelled since the destructive fires of 1824, and now exhibiting on the south and west sides splendid erections in the Grecian style of architecture, with piazzas underneath. These improvements, which extend over the front of the old parliament-house, or present court-house, have been executed chiefly by government, at a great expense. The entrance to the courts is at the south-west angle of the square; the great hall is 122 feet by 49, and has a lofty roof of carved oak, arched and disposed in the same style as that of Westminster Hall. In this hall or outer house generally sit two of the Lords Ordinary, and the floor during session is the daily resort of all persons connected with the courts. On a pedestal near the south end of the hall is a statue in white marble, of the late Lord Viscount Melville, executed in 1818 by Chantrey.

Adjoining the Parliament House are certain spacious apartments fitted up as libraries for the Faculty of Advocates and the Writers to the Signet. The Library of the former body was founded in 1682, at the instance of Sir George Mackenzie, then Dean of Faculty. The collection is now the largest and most valuable in Scotland, and is in every sense one of the noblest national libraries. By an act of parliament passed in the reign of Queen Anne, it is entitled to a copy of every work printed in Britain; and, with the sums annually disbursed in the purchase of useful and rare books, it is rapidly increasing. The library is under the charge of six curators, a librarian, and assistants. At present the collection is on the eve of removal to a large new building erected for its reception on the west side of the Parliament House, and facing the new approach from the south.

The Library of the Society of Writers to the Signet occupies a splendid modern erection of two stories, in the Grecian style of architecture, extending westward from the north-west corner of the Parliament House, and having a front to the Lawnmarket. This edifice contains two large and beautiful apartments, decorated in front of the book-presses with rows of columns, which produce a fine effect. These noble apartments have cost the society L.25,000. The library, like that of the Advocates, is under the charge of curators, a librarian, and assistants.

The Scottish Supreme Courts possess accommodations for their records, and the functionaries connected therewith, in a building styled the General Register House of Scotland, one of the most remarkable national edifices in the metropolis. It stands at the eastern extremity of Princes Street, fronting the thoroughfare of the North Bridge. The foundation was laid on the 17th of June 1776, and L.1200 were given by George III. out of the money arising from the sale of the forfeited estates, to assist in its erection. It was fully completed in 1822, at a very great expense, which has been defrayed by government. The building, which was planned by Mr Robert Adam, forms a square, with a quadrangular court in the centre, containing a circular edifice or dome fifty feet in diameter, which joins the sides of the court, leaving spaces at the angles for the admission of light. Viewed from the street, it presents a compact building of 200 feet in length, by a breadth of 120. Each of the corners is surmounted by a small turret, and the central tower is crowned with a dome. The interior consists principally of small fire-proof chambers, in which are deposited state papers, copies or records of all the title-deeds of property, and of all legal contracts, mortgages, &c.; also records of all suits at law from an early period.

The Post-Office establishment for Scotland is conducted in Edinburgh, and occupies a handsome new edifice of four stories in Waterloo Place. The duties of this well-regulated establishment are executed by a numerous body of individuals, amongst whom are a secretary, cashier, clerks, and letter-carriers. The produce of the Scottish posts is now upwards of L.207,000 annually, and the expense of management about L.55,000.

The Stamp Office for Scotland is also situated in Waterloo Place, a short way westward of the Post-Office, to which it bears a very considerable resemblance in point of architectural design. This establishment, which is under the superintendence of a comptroller, is subject to the Board of Stamps in London.

In looking along the noble line of Princes Street, the eye is arrested by a structure of modern date, occupying a situation at the northern extremity of the Earthen Mound, or that end adjoining the New Town. This edifice, which fronts the opening of Hanover Street, is entitled the Royal Institution Buildings, and is appropriated for the accommodation of a variety of institutions. It was founded in the year 1823, on a substructure of piles and cross bearers, rendered necessary by the nature of the ground, which consists of forced earth. The building is from a Grecian model, executed by Mr Playfair, and has a range of Doric columns on each side, and another range surmounted with a pediment in front. Owing to the opposition of the Princes Street proprietors, the structure is not sufficiently elevated. The interior accommodations consist of one large central hall for exhibitions, and an upper and lower range of smaller apartments on each side. Additions are at present making to the building by an extension in the direction of the Mound, which will very much improve its appearance. The Royal Institution, under whose auspices this edifice was founded, was incorporated by royal charter in the year 1827, for the purpose of encouraging the fine arts in Scotland. The primary object of the institution is the annual exhibition of pictures of modern artists, and the purchase of those which are deemed of sufficient merit to entitle them to a place in a regular gallery of paintings. The institution also occasionally offers exhibitions of paintings by the old masters. A separate establishment was founded in Edinburgh in 1826, by a body of artists, with similar objects in view, entitled the Scottish Academy of Painting, Sculpture, and Architecture, which has now also regular exhibitions.

The Royal Society of Edinburgh was incorporated by royal charter in 1783, for the purpose of encouraging philosophical inquiry, and discussing matters connected with nature and art. Its meetings, which are very numerously attended, take place twice a month during winter and spring, and it has published twelve volumes of transactions. It is governed by a president, several vice-presidents, and twelve counsellors. It possesses very splendid apartments, an extensive library, and a small museum, in the Royal Institution Buildings.

The Society of Antiquaries of Scotland originated in 1780, and was incorporated by letters under the great seal in 1783. The society is governed by a president, three vice-presidents, and a council of nine members, with a treasurer, two curators, a general secretary, and a secretary for foreign correspondence. The king is patron. The fee of admission is three guineas, and two guineas annually, or a life premium of twenty guineas. Its meetings are held every alternate Monday during winter and spring. The society possesses a museum, in which there is a considerable collection of antiquities, principally Scottish. Its apartments are situated in the Royal Institution Buildings.

The Board of Trustees, which was instituted for encouraging trade and manufactures in Scotland, was erected by letters patent in the year 1727. On its erection it was endowed with the sum of L.3800, and an annuity of L.2000 from government. It has since then received various accessions of revenue, chiefly from the forfeited estates, which now amounts altogether to L.7961. 13s. 8d. annually. The management of this capital is vested in twenty-eight trustees, consisting of peers, judges of the supreme courts, the lord advocate, bankers, and gentlemen of property, all of whom give their services gratis. Vacancies are filled up by the crown; five members form a quorum; and meetings are held periodically throughout the year. The chief object of this institution has hitherto been the encouragement of the manufacture of particular kinds of linen and woollen cloths; but it now extends its patronage to other branches, and pays, besides, L.500 per annum to the Royal Institution of Scotland for the Encouragement of the Fine Arts. It has an academy for instruction in drawing, and possesses a noble gallery of casts from the ancient sculptures. It has apartments in the Royal Institution Buildings.

The Highland Society of Scotland originated in the year 1784. In 1787 it was incorporated by royal charter, and assisted by a grant of L.3000 from the forfeited estates. In 1789 it received a further and annual grant of L.800 from the treasury. Its members exceed seventeen hundred, and are admitted by ballot at public meetings, each paying a life subscription of L.12. 12s. or an annual fee of L.1. 3s. 6d. The society is under the management of a president, four vice-presidents, a treasurer and secretary, two deputy-secretaries and collectors, and a body of thirty ordinary and ten extraordinary directors. The object of this institution was originally confined to improving the condition of the Highlands; but its patronage is now extended over the whole kingdom, and embraces every species of improvement in agriculture, management of cattle, and general country produce. It annually awards premiums in money and medals to the amount of L.1200, for the best specimens of live stock, shows of which are every season made in some particular district. The society has a handsome hall, model-room, and other apartments in Albyn Place, at the west end of Queen Street.

The Caledonian Horticultural Society, the object of which is the promotion of improvement in the cultivation of the best kinds of fruits, flowers, kitchen vegetables, and the like, was established in the year 1809. It is supported by the sale of shares of twenty guineas in value, or annual fees of two guineas. Its affairs are managed by a president, four vice-presidents, a secretary, a treasurer, an auditor, an artist, a council of twelve, a committee of prizes, and a garden committee. The society has an excellent experimental garden in the grounds of Inverleith.

The object of the Society of Arts, instituted in 1821, is to encourage the invention of machines calculated to improve manufactures, the discovery of chemical preparations of utility in the arts, and the exposition of facts tending to improve the natural products of the soil. The king is patron. The society has honorary, associate, and ordinary members. The latter pay L.1. 1s. annually, or a life premium of L.10. 10s. It distributes about L.80 every year in premiums for models, essays, and the like.

Nelson's Monument occupies the summit of a rocky eminence on the Calton Hill, and is one of the most prominent, though at the same time most unsightly objects in Edinburgh. It was begun by subscription soon after the death of Lord Nelson, whose actions it was intended to commemorate, but it was not finished till 1815. It consists of a lofty circular turret, with a stair inside, and is battlemented on the top. Round the base is a low structure in the same style of architecture, divided into apartments.

The National Monument occupies a prominent situation on the Calton Hill. It was begun by a body of subscribers in 1822, and was intended to be an exact model of the Parthenon at Athens. Its object was to commemorate those Scotchmen who had fallen in the different engagements by sea and land during the wars consequent on the French revolution; but it has been arrested in its progress for want of funds, and only twelve massive pillars of exquisite workmanship have as yet been completed.

A monument of a singularly elegant description, designed by Mr Playfair, and which is a reproduction, with some variations, of the choragic monument of Lysicrates, was erected in 1830–31 on a prominent situation on the Calton Hill. It is commemorative of the late Mr Dugald Stewart, professor of moral philosophy in the university of Edinburgh. A monumental erection, commemorative of Professor Playfair, is also placed on the Calton Hill, at the corner of the enclosure of the Royal Observatory; and more recently another to the memory of Robert Burns has been raised on an isolated eminence fronting the new High School. David Hume's Monument, within the old Calton Hill burying-ground, is also conspicuous.

Lord Melville's Monument, an elegant fluted column, in the centre of St Andrew Square, was finished in 1828. It was raised by subscriptions chiefly among gentlemen connected with the royal navy. On the summit is a colossal figure of the above nobleman, cut in freestone. This beautiful column rises to the height of 136 feet, is modelled after Trajan's pillar at Rome, and forms altogether a very prominent and striking object.

In George Street, at the crossing of Hanover Street, stands a pedestal, surmounted with a figure in bronze of George IV., erected in 1832, in commemoration of the visit of his majesty to Scotland in 1822. A similar pedestal and figure of Mr Pitt were erected in George Street, at the crossing of Frederick Street, in 1833. Both statues are by Chantrey.

During the reign of episcopacy in Scotland, Edinburgh was the seat of a bishop. It is now the place of meeting of the General Assembly of the church, and the seat of a synod and presbytery. Ecclesiastically, the ancient and extended royalty comprehend thirteen parochial divisions, eight of which have one clergyman each, and five are double or collegiate charges. That portion of the town which is not within these divisions belongs either to the parish of Canongate, or to that of St Cuthbert's. Originally the city consisted of only one parish, of which the ancient church of St Giles was the place of public worship. This venerable fabric, which occupies a prominent situation in the centre of the Old Town, on the south side of the High Street, is of unknown origin and date. It has been presumed, however, that a church existed on its site as early as the year 854; but the first certain intelligence regarding it occurs in 1359, when a charter was granted by David II. bestowing some land on a chaplain who officiated at one of its altars. The building, previously to certain alterations which were made upon it, was cruciform, and of Gothic architecture, but rather substantial than elegant. From the centre of the whole there rises a square tower, the top of which is encircled with open figured stone work, whilst from each corner of the tower springs an arch, and the four meeting together produce the appearance of an imperial crown. These arches are highly ornamented with small pinnacles, and from the apex rises an equally ornamented short spire. This elegant object is prominent above the whole of the town; and being 161 feet in height, it may be seen at a great distance. After the Reformation, the church was divided by internal walls into separate places of worship. By these and other subsequent alterations, the choir or eastern division formed the High Church; the one occupying the centre of the building, was styled the Old Church; another entering from the south-west corner, the Tolbooth Church; and one at the north-west corner was named the New North Church. Between the years 1829–33 this extensive edifice was remodelled, and greatly improved in external appearance, by an entire casing of new walls. It now forms two churches; and contains also a spacious hall intended as a place of meeting for the General Assembly. The design of the remodelled church does great credit to its architect, Mr William Burn.

Trinity College Church, which is next in point of antiquity to St Giles, is situated on the low ground east from the North Bridge. It was founded in 1462, by Mary of Gueldres, widow of James II.; and in 1502 James IV. invested it with some additional revenues. At the period of the Reformation it shared the fate of the other ecclesiastical establishments of the kingdom. Its revenues were in 1567 given to Sir Simon Preston, provost of Edinburgh, who again presented them to the town council as a common fund. In 1587 the magistrates restored an hospital which had formerly belonged to the establishment, and which still exists. The body of its royal foundress lies interred in an aisle on the north side of the church, and within its walls are likewise the remains of many persons celebrated in Scottish history.

The Old Grayfriars Church was built in 1612, but it was not constituted a parish church till 1722. Previously to this, in May 1718, its spire was blown up by gunpowder, which had been lodged in it by the town authorities for security. The New Grayfriars Church was built in 1721. Both of these buildings, which are separated only by a wall, were erected on what was formerly the garden ground of the monastery of Grayfriars, in the south part of the town, and which, on the demolition of the friary in 1559, was conferred by Queen Mary on the town, to be used as a public cemetery. The Old Grayfriars Church is remarkable for being the place where the National Covenant was begun to be signed in 1638, and for having had the historian of Charles V. as its minister.

The Tron Church, which stands in the High Street, was begun in the year 1627, and opened for public worship in 1647. Its appellation is acquired from the circumstance of a tron or weighing beam having formerly stood upon the spot. Its steeple, formed of wood and covered with lead, was destroyed during the great fires of 1824, but has since been replaced by an elegant stone spire of 160 feet in height.

Lady Yester's Church was founded in 1647, by Dame Margaret Ker, Lady Yester. This pious lady gave the magistrates fifteen thousand merks for the erection of the building, and made a bequest of a thousand merks per annum for the stipend of a minister. The original edifice having become ruinous, it was rebuilt in 1803. It is situated in Infirmary Street, and has no spire.

St Andrew's Church was erected in the year 1781. The body of the building is of an oval form, with an exceedingly handsome spire in front, partly resting on four Corinthian pillars, and rising to a height of 168 feet.

St George's Church, which is situated on the west side of Charlotte Square, was founded in the year 1811, and opened in 1814. It is a huge square fabric, in a plain Grecian style, and is capable of accommodating about 1600 persons. From the centre rises a tower surmounted with a dome, 150 feet in height, somewhat in imitation of St Paul's. The building cost L.33,000.

St Mary's Church stands in Bellevue Crescent, and was opened in the year 1824. It is of an oblong figure, with a front of considerable elegance, consisting of a portico with a range of pillars of the Corinthian order, supporting a pediment, from which rises a spire.

St Stephen's Church, situated at the northern extremity of St Vincent Street, was opened in 1828, and cost L.25,000. It is ornamented with a square tower of solid proportions, 162½ feet in height, terminated at the top with a balustrade. The church can accommodate 1600 persons.

The foregoing churches are all under the patronage of the civic corporation. The clergy, eighteen in number, are supported by an assessment, called annuity-tax, levied within the ancient and extended royalty on all houses and shops, with the exception of the dwelling-houses of the members of the college of justice. The following table, drawn up from official documents, exhibits the nature and amount of the funds belonging to the church establishment. It is for the year 1830.

Assessment, or annuity-tax.........	L.8581	0	0
Seat rents of the churches............	7240	0	0
Impost, a small assessment............	1329	0	0
Proportion of shore-dues at Leith...	3616	0	0
Dues or customs of the pack, Leith,	21	0	0
Proportion of ale and beer duty......	137	17	8
Lady Yester's bequest.................	13	17	9
Dues at Port-Hopetoun..............	24	8	0
	L.20,963	3	5

Exclusively of the seat-rents, which are appropriated to ordinary purposes, the foregoing sums, when properly collected, afford a stipend to each minister averaging L.611.

St Cuthbert's Church is situated in the low ground between the western extremity of Princes Street and the castle. There formerly stood on the same spot an ancient edifice, one of the earliest places of Christian worship in this part of Scotland. The modern church is a large plain building, with a spire at the western extremity; it is of date 1789, and stands in the midst of an extensive burying-ground. In modern times it has been popularly named the West Kirk, from its situation to the west of the metropolis. The populous parish of St Cuthbert's has likewise at present (1833) five chapels of ease, one of which, in Clerk Street, erected in 1823, is a handsome building.

The church of the parish and subordinate burgh of Canongate is of date 1688, and was erected at an expense of L.24,000 sterling. It is situated in the midst of a burying-ground, on the north side of the Canongate, but having no spire, it is not conspicuous as a place of worship.

Lady Glenorchy's Chapel, a simple square edifice, situated near the College Church, was founded and endowed by the pious lady whose name it bears, in the year 1772, and was opened in 1776. It is under the government of the established ecclesiastical courts.

The Gaelic Chapel, the only one in Edinburgh in which the service is conducted in the Celtic tongue, is situated in North College Street. It was erected in the year 1815, and is under the jurisdiction of the established church courts.

There are five chapels in Edinburgh belonging to the communion of the Scottish Episcopal church, to which a considerable number of the higher classes are attached. The most elegant of these perhaps is St John's, situated at the west end of Princes Street. This edifice was founded in 1816, and finished in two years, at an expense of L.15,000. It is of the florid Gothic style, from a design by Mr Burn, measures 113 feet in length by sixty-two in breadth, and is terminated at the western extremity by a beautiful square tower, rising to a height of 120 feet. Another Episcopal chapel, of tasteful Gothic architecture, is that of St Paul's in York Place. It was designed by Mr Elliot, founded in 1816, and finished in 1818 at an expense of about L.12,000. It measures 122 feet by seventy-three, and from each corner there rises a small circular turret. St George's Chapel, a much smaller building, is also situated in York Place, and of date 1794. St James's Chapel is erected in the line of houses in Broughton Place. St Peter's Chapel is a similar plain edifice in Roxburgh Place. St Paul's Chapel, Carrubber's Close, is the oldest episcopal chapel in Edinburgh, having been erected about the end of the seventeenth century.

The Roman Catholic communion has a principal place of public worship, and a subordinate one. The former is a large structure, with a Gothic gable front, situated in Broughton Street, and was built in the years 1813–16, at an expense of about L.8000, raised by subscriptions and collections. The latter is situated in Blackfriars Wynd. Another Roman Catholic chapel is at present in the course of erection in Bristo Street, in the southern part of the town.

Edinburgh possesses a number of places of public worship belonging to the United Secession church, and other presbyterian dissenting bodies. The following are those of most note. Nicolson Street Chapel was founded in 1819, and was raised at an expense of L.6000. It has a broad and lofty Gothic front, with pinnacles rising to the height of ninety feet. Broughton Place chapel is a modern building, with a Grecian front, portico, and range of Doric columns. Rose Street Chapel is a handsome structure of plain Grecian architecture, built in 1830. The Cowgate Chapel, now belonging to the Secession, was formerly occupied by an episcopal congregation, from whom it was purchased; a recess in the interior is decorated by some oil paintings of Runciman. The other chapels are at Stockbridge, Lothian Road, Bristo Street, Potterrow, and the Vennel.

Edinburgh is the seat of one of the presbyteries of the Associate Synod of Original Seceders, and of two congregations. One chapel is situated at the foot of Infirmary Street, and the other in Richmond Street. The former is under the superintendence of the Reverend George Paxton, professor of divinity, and author of the Illustrations of the Holy Scriptures; and the latter under that of the Reverend Dr M'Crie, author of the lives of Knox and of Melville.

There is also a congregation belonging to the Original Burgher Associate Synod, and one to the Cameronian communion, a representative remnant of the old Covenanters.

Edinburgh is likewise the seat of a presbytery of the Relief Synod, and there are in the city five places of worship belonging to that communion. Besides the foregoing churches and chapels in Edinburgh, there are two chapels of Scottish Independents, one of English Independents, four of Baptists, one of Methodists, one of Bereans, one of Unitarians, one of Glassites, one of the New Jerusalem Church or Swedenborgians, one of the Society of Friends, and a Jews' synagogue.

Edinburgh has long derived celebrity from its educa-

Ins u- tio and soc ies.

tional establishments, the chief of which is the University. This institution dates its origin about the year 1583, when the first professor was appointed; and under the patronage of James VI. it soon assumed the character of an ordinary college. About the year 1660, by means of benefactions from public bodies and from private individuals, the establishment had attained a respectable rank among similar institutions. As a school of medicine it first rose into repute under Dr Alexander Munro, who became professor of anatomy in 1720; and in this branch of science it afterwards attained a distinguished pre-eminence, from possessing professors remarkable for their abilities and success as teachers. In the other branches of knowledge, its reputation was gradually exalted to the highest pitch by Maclaurin, Black, Fergusson, Stewart, Robertson, and other eminent men. The decay and insufficiency of the old buildings had long been complained of; and at length, in 1789, the foundation was laid of a new and extensive structure, the plan of which had been furnished by Mr Robert Adam. But this plan, after it had been partly carried into execution, was altered and modified; and the building has been finished in conformity with a very skilful and tasteful design furnished by Mr William Playfair. It still (1833), however, wants a dome and other interior finishings, to render it complete. This splendid edifice forms a parallelogram, inclosing a quadrangular court. The sides of this court are occupied with the class-rooms, the museum, and the library. In the middle of the front are three entrances to the court, consisting of lofty porticos penetrating the building.

The number of Professorships is about thirty, and these are divided into four Faculties, viz. Theology, Law, Medicine, and Arts. The latter includes all the chairs devoted to Literature and General Science. The Principal and Professors constitute the Senatus Academicus; and the Lord Provost of the city for the time being assumes the title of Lord Rector.

The magistrates and town council are the patrons of the University, and have the nomination to the greater number of the chairs; the others are under the patronage of the crown, except three, the patronage of which is shared by the faculty of advocates, the writers to the signet, and the town council. The degrees it bestows are the same as in the other Scottish colleges, namely, those of doctor of divinity, doctor of laws, doctor of medicine, and master of arts. The terms of the college are a winter session of about six months, beginning in November, and a summer session of about three months, from May to August. During the latter term the lectures given are confined to botany, natural history, midwifery, medical jurisprudence, and clinical lectures on medicine and surgery. The total number of students who matriculated in the session 1829–30 was 2186.

The College Museum is particularly rich in objects of natural history, amongst which are specimens of upwards of three thousand birds foreign and British. The Museum occupies two large rooms, each ninety feet by thirty, besides minor apartments.

The College Library consists of upwards of 70,000 volumes. It is supported from a fund formed by a contribution exigible from every student who matriculates, five pounds payable by every professor on his admission, and a portion of the fees of graduates both in medicine and arts. It is besides entitled, along with the other libraries belonging to the Scottish universities, to a copy of every work published in Great Britain. There is also an excellent collection of books on theology and church history connected with the class of divinity, and which is supported by certain annual fees paid by the students attending the class. The principal apartment, called the Library Hall, is 198 feet in length by fifty in width, and is certainly one of the most spacious and elegant apartments in the kingdom.

The celebrity of Edinburgh as a place of education has been in some measure derived from the schools of a number of private lecturers of eminence in their several departments of science, particularly in medicine. These lecturers are chiefly members of the Royal College of Surgeons. This body, which was incorporated by charter in 1778, confers the same privileges on medical students as the University does, that of doctor of medicine excepted. The Royal College possesses a beautiful edifice in Nicolson Street, from a design by Mr Playfair. Towards the street it is adorned with a lofty portico, which has a striking effect; and the details, though elaborate, are exquisitely finished, and in admirable harmony with the design. It cost the Royal College L.19,060, and forms several splendid halls for the accommodation of the members and the Pathological Museums. These museums, enriched by the collections of the late Dr Barclay and others, exhibit a valuable repository of preparations and objects calculated to advance the study of surgical science.

The Royal College of Physicians was established in 1681, by a charter of Charles II.; and the number of its fellows, resident and non-resident, is now about a hundred. The meetings of the body take place in the Physicians' Hall, a handsome edifice in George Street, of the Grecian style, and erected in 1775. It contains a good library.

The High School is the chief seminary in Edinburgh for classical education, and has long maintained an eminent place amongst similar establishments. Its origin may be traced to an early period in the sixteenth century; but it has been greatly extended and improved in recent times. It now occupies a splendid structure on the south side of the Calton Hill, facing the road that sweeps round that eminence. The design was furnished by Mr Thomas Hamilton, and the foundation-stone was laid on the 28th of July 1825. The main building extends about two hundred and seventy feet in front, and in the centre of the edifice is a magnificent hexastyle Doric portico. On each side of the portico there is a corridor, the entablature of which is supported by six Doric columns. The apartments, which are entered through a spacious play-ground, consist of a large hall of seventy-five by forty-three feet, and rooms for the accommodation of the various classes taught in the establishment. The cost of this extensive building was about L.30,000, which was partly raised by subscription. The patronage of the High School is vested in the town council of the city. The system of education is conducted by a rector and four classical masters, with teachers of writing, arithmetic, and mathematics. The usual number of pupils is from six to seven hundred.

The Edinburgh Academy is a similar institution with the High School, but its fees are higher. It was begun a few years ago by a society with a capital of L.12,900, which may be augmented to L.16,000, raised by proprietory shares of L.50 each. The superintendence of the establishment is vested in fifteen directors, chosen by the proprietors from their own body. The system of education is nearly the same as that pursued in the High School. There are here also four classical masters and a rector.

Besides the High School and Academy, there are a number of private academies throughout the city, several free schools, and many on moderate scales of charges. There are several sessional schools, which are entirely under the control and patronage of the kirk-sessions of the respective parishes where they are situated. The teacher is allowed a fixed salary from the funds of the church, so that the fees are extremely moderate. The private schools of Edinburgh altogether are computed to amount to about two hundred.

The School of Arts was established in 1821. The students are young men belonging to mechanical and trading professions, and are divided into junior and senior classes. The session is from October to April, during which period there are given every evening lectures on arithmetic, algebra, mathematics, geometry, and other scientific subjects. The students are under the guidance of several regular lecturers, and the institution possesses a library and collection of apparatus and models. It is supported by the sale of tickets of admission, and by voluntary subscriptions.

An institution called the Edinburgh Association for Popular Instruction was established in 1832, for the purpose of affording information by popular lectures, on terms and at hours convenient for the middle classes of both sexes, particularly those who are actively engaged during the day. The association is distinguished from some other institutions for education, by being entirely dependent upon the fees of subscribers, instead of relying for support on gratuitous contributions. It is conducted by directors chosen annually from among the subscribers.

The Scottish Naval and Military Academy was opened on the 8th of November 1825. Its principal object is to afford to young gentlemen intended for the army, navy, or the East India Company's civil or military service, a systematic course of education, in order to qualify them for any of these departments. The institution comprehends classes for fortification, military drawing, surveying, landscape and perspective drawing, arithmetic, algebra and geometry, the higher mathematics, natural philosophy and navigation, elocution, geography, ancient and modern languages, fencing, gymnastics, and military exercises. The establishment is supported by a body of proprietors, holding shares of L.10 each, subscribers who pay one guinea or more per annum, and donors. The management is confided in a body of honorary office-bearers, twenty-seven extraordinary and fourteen ordinary directors, with a chairman and trustees. The king is patron.

The Royal Academy, better known by the name of the Riding School, was established about the year 1760. The members were incorporated by letters-patent in 1764, with the title of the Royal Academy for Teaching Exercises. The directors of this academy are eighteen in number, and are persons amongst the most elevated in rank both in the city and county. The school is superintended by two masters.

The Botanical Garden is about twelve acres in extent. The first ground appropriated to this purpose was in St Ann's Yards, a spot situated near the North Bridge. From this it was in 1767 removed to Leith Walk, and thence to its present situation in the Inverleith grounds, on the road from Edinburgh to Newhaven, in 1822–24.

The new Observatory is situated on the Calton Hill, and belongs to the Astronomical Institution. It is built after a design by Mr Playfair, in the form of a cross, and is sixty-two feet each way. The centre is surmounted with a dome.

The Wernerian Natural History Society is an unincorporated association, formed in 1808 for the promotion of the study of natural history. The name was assumed from Werner, the distinguished mineralogist. It has associate and corresponding members, and holds its meetings in the university buildings.

Besides those already mentioned, there are a number of other societies, namely, the Plinian Society, instituted in 1823; the Diagnostic Society, instituted in 1816; the Medico-Chirurgical Society; the Royal Physical Society; the Royal Medical Society; the Hunterian Medical Society; the Harveian Society, instituted in 1782; the Speculative Society, for improvement in composition and in public speaking; the Select Forensic Society; the Juridical Society, instituted in 1773; the Scotch Law Society, instituted in 1815; the Philalethic Society, instituted in 1792; the Adelpho-Theological Society, instituted in 1758; the Theological Society, instituted in 1776; the Edinburgh Academical Club, instituted in 1828; the Phrenological Society, instituted in 1820; Edinburgh Harmonists' Society; Edinburgh Royal Naval Club; Caledonian United Service Club; the Pitt Club; the Celtic Society, instituted in 1820; the Highland Club of Scotland, instituted in 1825; St Fillan's Highland Society, instituted in 1819; the Six Feet Club, instituted in 1826; the Skaiting Club; the Duddingston Curling Society; the Edinburgh Company of Golfers, instituted in 1744; the Burntsfield Links Golfing Society; the Edinburgh Burgess Golfing Society; the Thistle Golf Club; the Royal Company of Archers, instituted in 1703 by a charter of Queen Anne, and now constituted the king's body guard in Scotland; the Brunswick Cricket Club, established at Edinburgh in 1830; the Edinburgh Chess Club, instituted in 1822; the Edinburgh Quoiting Club; the Edinburgh Shakspearian Club; the Edinburgh Anatomical Society, instituted in 1833; and the Edinburgh Ethical Society, for the study and practical application of phrenology, instituted in the same year. There are various other societies and clubs, which have been established from time to time in the Scottish metropolis, but they are of a character too unimportant to require notice in this place.

In addition to these, there are several associations of a literary nature. The principal is the Edinburgh Subscription Library. This library was instituted in the year 1794, and is the property of a body of subscribers, whose entry-money is twelve guineas, and who pay an annual fee of one guinea. The others are, the Select Subscription Library, instituted in 1800; the Edinburgh Subscription and Circulating Select Library; the Edinburgh Mechanics' Subscription Library, instituted in 1825; the Hope Park Library, instituted in 1816; and the Bakers' Record Office and Library, instituted in 1828.

The chief of the associations for religious purposes is the Society for Propagating Christian Knowledge, instituted in 1701, and incorporated by a charter of Queen Anne in 1709. The others are, The Scottish Bible Society; the Edinburgh Auxiliary Bible Society; the Edinburgh Auxiliary Naval and Military Bible Society; the Scottish Missionary Society; the Edinburgh Auxiliary Church of England Missionary Society; Edinburgh Auxiliary to the London Missionary Society; Baptist Home Missionary Society; Society for Improving the System of Church Patronage in Scotland; Edinburgh Philanthropic Society; Edinburgh Association in Aid of the Moravian Missions; Society for Promoting Christianity among the Jews; Society for Promoting Religious Knowledge among the Poor; Highland Missionary Society; Edinburgh Religious Tract Society; Edinburgh Society in Aid of the Irish Evangelical Society; Edinburgh Society for Promoting the Religious Interests of Scottish Settlers in British North America; and a few others.

Besides these there are several societies who associate the promotion of education in particular places with religious purposes, and a number of branches of different English societies for the accomplishment of similar objects.

Educat-
al hospi-

Heriot's Hospital was founded about the beginning of the seventeenth century. The founder, George Heriot, was born in the parish of Gladsmuir, and in the year 1597 he was appointed goldsmith and jeweller to James VI. He died in London, whither he had removed on the accession of James to the English throne, on the 12th of February 1624, leaving a fortune, it is supposed, of not less than L.50,000.

Of this sum L.23,625. 10s. 3½d. were, by his bequest, appropriated to the founding and endowing of the hospital which bears his name, for the maintenance and education of children, the sons of burgesses of the city "who are not able to maintain them." The magistrates, town council, and ministers of the town, were nominated the governors; and certain trustees were appointed to superintend the execution of the will. The building of the hospital, which is from a design by Inigo Jones, was begun in 1628, and, after some interruptions, completed in 1650, at an expense altogether of L.30,000. It was not however opened for its legitimate purpose till 1659, when thirty boys only were admitted. There are now one hundred and eighty on the establishment, all of whom are comfortably lodged, fed, and clothed, and every pains bestowed upon their education, which comprehends Greek, Latin, English, writing, arithmetic, book-keeping, mathematics, and geography. On leaving the hospital they are furnished with a liberal supply of articles of dress, of their own choosing; and such of them as are apprenticed to trades receive an apprentice fee of L.50, besides an allowance of clothing at the expiration of their indentures. Boys who distinguish themselves by their literary attainments, and who are qualified to enter the university with a view to the learned professions, receive bursaries of L.30 per annum for four years. Ten other bursaries of L.20 each, for the same period, are bestowed upon young men unconnected with the hospital who give proofs of superior talents. Boys are not admitted under seven years of age, and generally leave it at fourteen. The hospital is situated in the southern part of the town, and is one of the most remarkable buildings connected with the city. It is three stories in height in the central parts, and four stories at the corners, with an interior quadrangle or court. In 1832–33, the structure was improved in its external appearance, and a lodge was erected at the principal entrance, which is a beautiful miniature of the hospital.

The founder of George Watson's Hospital died in 1723, leaving the sum of L.12,000 sterling for the erection of an hospital for the maintenance and education of the children and grandchildren of decayed merchants in Edinburgh. The will of the donor, however, was not acted upon till 1738, when the original sum had accumulated to L.20,000. In 1721 twelve boys were admitted; and these have now been increased to eighty. In point of lodging, education, and otherwise, they are upon much the same footing as in Heriot's Hospital. On leaving the house they receive an apprentice fee of L.10 per annum for five years; and on attaining twenty-five years of age, if unmarried and able to show testimonials of good behaviour, they receive a premium of L.50. Boys preferring a college education receive L.20 per annum for six years. The managers are the master and twelve assistants of the Merchant Company, with the treasurer, four old bailies, the old dean of guild, and the two ministers of the Old Kirk parish.

In 1759 John Watson, writer to the signet in Edinburgh, bequeathed the whole of his property to trustees, to be laid out in such pious and charitable purposes within the city as they might think proper. In 1781 this fund amounted to L.4721. 5s. 6d. From that period, by the excellent management of the trustees, it accumulated to upwards of L.90,000. As the donor had not pointed out any particular mode of appropriating his bequest, the trustees originally contemplated the institution of a foundling hospital; but they finally determined on erecting an edifice appropriated "for the maintenance and education of destitute children, and bringing them up to be useful members of society, and also for assisting in their outset in life such of them as may be thought to deserve and require such aid." A splendid and extensive building, in the Grecian style of architecture, after a design by Mr Burn, has accordingly been erected for the purpose, on the Dean grounds, to the westward of the city. Children of both sexes are here maintained and educated; the girls, however, are only instructed in English, writing, and arithmetic.

The Merchant Maiden Hospital originated in 1695, and was incorporated by an act of parliament in 1707. Its objects are the maintenance and education of the daughters of merchant burgesses in the city, who are instructed in English, writing, arithmetic, geography, French, and needle work. It contains nearly a hundred inmates, who are received at from seven to eleven years of age, and who go out at seventeen. On leaving the establishment, each receives the sum of L.9. 6s. 8d. The new hospital is of Grecian architecture, and cost L.12,250. It was founded in 1816, and measures a hundred and eighty feet in length by nearly sixty in breadth, with a portico in front. It is situated near the Meadows.

The Trades' Maiden Hospital, for the maintenance and education of the daughters of decayed tradesmen in Edinburgh, was begun in 1704, and its governors were incorporated in 1707. It was founded and endowed by the trades of the city, and since its institution it has supported about fifty girls.

The Orphan Hospital was incorporated by a charter of George II. granted in 1742. It receives orphans from all parts of the country, and generally maintains and educates about one hundred and fifty children of both sexes. A very elegant building, designed by Mr Hamilton, for this institution, has just been finished (1833), on the property of Dean, near John Watson's Hospital.

James Donaldson, Esq. of Edinburgh, left at his death in 1830, about L.240,000 to six trustees, for the purpose of endowing an hospital for boys, to be called Donaldson's Hospital. An establishment of this kind is therefore about to be commenced.

Hospitals for the indigent, &c.

The Trinity Hospital, the oldest charitable institution in the city, was founded by Mary of Gueldres in the year 1461. The number of persons maintained in the house is at present forty; and there are besides about one hundred out-pensioners. The funds of the institution consist of lands in the county of Edinburgh, heritable property in the city and in the town of Leith, and money in bonds. The magistrates and town council are the governors, and there are regular office-bearers and house-directors.

James Gillespie, the founder of the hospital known by his name, was a shopkeeper in Edinburgh, and, by a will dated 1796, devoted the greater part of his property to endow an hospital for the maintenance of indigent old men and women, and for the elementary education of one hundred poor boys. A house for this purpose was accordingly erected in 1801. The number of its inmates is about forty. Its governors are, the master and twelve assistants of the Merchant Company, four old bailies, the old dean of guild, and the ministers of the Tolbooth and St Stephen's Churches. The name of Gillespie has a preference in admission.

The principal resources for the support of the poor are an assessment, and the collections made at church doors. The amount of money collected for their use in 1833 was L.13,479. 19s. 4d., whereas in 1814 it was only L.6943. 19s. 10d. Edinburgh, as regards the poor, is divided into three districts, the ancient and extended royalty, the parish of St Cuthbert's, and the Canongate, each of which has a house for the reception of paupers, with peculiar funds and a separate board of management. The City Poors-house, which was erected in 1743, supports six hundred persons within doors, affords regular aid to upwards of a thousand, grants to others temporary relief, and maintains about five hundred and thirty children at nurse. The expense incurred for each individual in the establishment is about L.8 per annum.

Besides these public institutions for the relief of the poor, there are several other charitable associations of a private nature. The principal are, the Society for the Suppression of Begging; the Benevolent Strangers' Friend Society, instituted in 1816; a Society for the Relief of the Destitute Sick, instituted in 1785; a Society for the Relief of Indigent Old Men, instituted in 1806; two similar institutions for the Relief of Indigent Old Women, instituted in 1797; the Edinburgh and Leith Seamen's Friend Society, for relieving poor shipwrecked or distressed seamen; and the Orkney and Zetland Society, for relieving such distressed natives of these islands as casually find their way to Edinburgh.

The Royal Infirmary was established in Edinburgh in the year 1736. The building, which is situated in Infirmary Street, consists of a body and two wings, all of four stories, the floors of which are divided into wards fitted up with ranges of beds sufficient to accommodate 230 patients. It also contains a theatre for chirurgical operations, in which 200 students can attend. All classes of persons are admissible into the Infirmary, on a guarantee being given that in case of death their bodies shall be removed. Patients suffering from accidental injuries are admitted without any stipulation. The expense incurred by this institution is liquidated by endowments, private subscriptions, *post-mortem* bequests, and collections at the doors of churches and chapels of all persuasions.

The Lying-in Hospital is adapted to the reception of all poor and unfortunate females requiring aid, and having no home at which they can be attended to. Besides this there are several other institutions of a similar nature, without hospitals, such as the Edinburgh General Dispensary and In-lying Institution; the Maternity Charity; the Edinburgh Lying-in Institution for delivering poor married women at their own houses, instituted in 1824; the Edinburgh New Town Lying-in Institution, instituted in 1825; and the Society for Relief of Poor Married Women of respectable character when in Child-bed, instituted in 1821.

The Public Dispensary, the oldest institution of this kind in the city, was founded in 1776. Besides this there are the following local dispensaries: The New Town Dispensary, instituted in 1815; the Western General Dispensary, instituted in 1830; the Eye Dispensary of Edinburgh; the Edinburgh Western Dispensary for Diseases of the Eye and Ear; and the Institution for Relief of Incurables. All these benevolent establishments afford medicines and advice to the poor gratis.

The Magdalen Asylum, which has for its object the reclaiming of unfortunate females, was founded in the year 1797. From fifty to sixty persons can be accommodated in the asylum, where they are all kept employed at useful occupations. The income of the house for the year ending in 1831 amounted to L.1183. The building is situated in the Canongate.

The Asylum for the Blind, situated in Nicolson Street, was opened in 1793, and is chiefly supported by voluntary subscription. Another for females, the former being confined to males, was established in 1822. The men are constantly employed in making mattresses, cushions, baskets, and other articles; the females in sewing and knitting. The number of inmates in these establishments is about 120, who receive instruction, partly according to the Abbé Sicard's plan, and partly according to methods which have been devised in the institution. See article Blind.

The Deaf and Dumb Institution, occupying a large edifice in the northern part of the New Town, was established in 1810, and contains upwards of seventy boys and girls, who receive the elementary and most useful branches of education. See article Deaf and Dumb.

The Lunatic Asylum, situated at Morningside, was opened for patients in 1813. The expense of its erection was defrayed by private subscriptions, and a grant by government of L.2000 from the forfeited estates. The establishment is managed by a body of directors and two physicians and surgeons. Inmates are received on paying a board regulated in amount by circumstances.

The most prominent of the provident and insurance societies is the Ministers' Widows' Fund, instituted in the year 1744. From this fund the widows of clergymen receive annuities for life, regulated in amount by the annual contribution previously made, and which varies from L.3. 3s. to L.7. 17s. 6d. The management of this fund is entrusted to the presbytery of Edinburgh and the professors of the university. The next in importance is a society formed for the benefit of the sons of the clergy, instituted in 1790. Another has recently been formed for the benefit of the daughters of the clergy. There are, besides, a Friendly Society of the Ministers of the Relief Synod, instituted in 1790; a Friendly Society of Dissenting Ministers, instituted in 1797; a society for the management of the Episcopal Fund, for affording small additions to the stipends of the poorer clergy of the Episcopal communion; a Medical Provident Institution of Scotland, instituted in 1826; and a Society for Relief of the Widows and Children of Burgh and Parochial Schoolmasters, instituted in 1807. There are likewise a variety of humbler associations, on various principles, throughout the city, as well as a large number of insurance companies.

Banki institu tions.

Although not an extensive trading or commercial town, Edinburgh exerts great influence over all branches of commerce in Scotland, by means of its banking associations, which supply capital to almost every seat of industry throughout the country. The oldest institution of this description is

The Bank of Scotland, which was established at Edinburgh in 1695, by charter from William III. and the Scottish parliament. The capital stock of the company was originally L.100,000 sterling, raised by shares differing in amount from L.83. 6s. 8d. to twenty times that sum. The capital has since been raised to a million and a half sterling. Notes were first issued by this bank in 1704. The establishment occupies a large and conspicuous building near the head of the Earthen Mound.

The Royal Bank of Scotland was instituted in 1727, by royal charter. Its original capital was L.111,000 sterling. In 1738 this capital was raised to L.150,000, and subsequently to L.2,000,000. The banking house is situated in St Andrew Square, in the building formerly occupied by the Excise Office.

The British Linen Company's Bank was established in 1746, with a capital of L.100,000. This capital has now increased to L.500,000. The banking house is also situated in St Andrew Square.

All the other banks in Edinburgh belong either to private persons or to joint-stock companies. Of the former there are seven, only two of which issue notes; these are, Sir William Forbes and Co. and Ramsays, Bonars, and Co. The joint-stock banks are, the Commercial Banking Company of Scotland, instituted in 1810; and the National Bank of Scotland, instituted in 1825, which now possesses a charter of incorporation.

Place publi amuse ment.

The present Theatre Royal was built shortly after the commencement of the New Town, in 1768. Previously to this period the theatrical performances of the city were exhibited in the Canongate, where a play-house was erected in 1746, in opposition to a rival establishment in the

Cowgate. The present house, although rather small, and externally of a very plain appearance, is in its internal arrangements one of the neatest and most commodious houses in Britain. The company of actors established here is generally considered as the best to be met with out of London. But, though for many years under able management, the fortunes of the establishment are by no means in a flourishing state. It is situated at the extremity of the North Bridge, adjacent to Princes Street. There is also a Minor or Summer Theatre, called the Adelphi, which is situated at the head of Leith Walk.

Assemblies and balls, under the patronage of ladies of distinction, are held every winter and spring in a large building in George Street, called the Assembly Rooms, erected in 1787. This edifice has a plain external appearance, relieved, however, by a portico and pillars in front. Its principal apartment measures ninety-two feet in length by forty-two in breadth and forty in height, and is occasionally used for concerts, public meetings, and other purposes.

Perhaps the most beautiful feature of Edinburgh in its modern state consists in the highly ornamental pleasure-grounds which occupy the open spaces between the Old and New Town, as well as between the latter and the second New Town. The low grounds to the east and west of the Earthen Mound continued for about fifty years after the commencement of the New Town in a very marshy and unprofitable condition. At length, in 1821, under the authority of an act of parliament, the ground on the west was drained, inclosed, laid out, planted, and highly beautified with walks, and has since been opened to the proprietors or tenants of property in Princes Street, or others, on payment of an annual fee. In 1832–33 the ground on the east was similarly inclosed and beautified. Before the year 1820 the greater part of the ground north of Queen Street was inclosed and laid out in gardens or promenades in the same tasteful and pleasing style.

In the year 1722 a marshy ground, part of the ancient Boroughmuir, in the southern environs of the city, was inclosed, drained, and traversed by extensive broad walks, skirted with trees, for the accommodation of the citizens. These public grounds, which receive the appellation of the Meadows, and bear some resemblance to St James' Park in London, are bordered with extensive open downs, called Burntsfield Links, which are also open to the public, and form a place of agreeable recreation for youth.

I rature.

Edinburgh has for some time been distinguished as a mart of literature, and as a place the inhabitants of which are noted for cultivated tastes and habits. This character, however, is not of much older date than the latter part of the eighteenth century. Previously to that time it seldom produced works of merit. The early editions of the Encyclopædia Britannica were the first large works which issued from the Edinburgh press. But the era of a new system of publishing commenced with the establishment of the Edinburgh Review in the year 1802. The person to whom Edinburgh has latterly been most indebted for an increase of its literary reputation was Sir Walter Scott, whose poetical productions appeared at intervals from 1802 till 1812, and whose novels and tales began to be published in 1814. The principal periodical works now published in Edinburgh are, the Edinburgh Review, the Edinburgh Medical and Surgical Journal, the Journal of Agriculture, and the Edinburgh Philosophical Journal, quarterly; the Presbyterian Review every two months; Blackwood's Edinburgh Magazine, Tait's Edinburgh Magazine, the Christian Instructor, the United Secession Magazine, and the Christian Herald, monthly; and the Edinburgh Almanack annually. There are ten newspapers published in Edinburgh, namely, the Caledonian Mercury, and Edinburgh Evening Courant, on Monday, Thursday, and Saturday; the Gazette, the Observer, and the Advertiser, on Tuesday and Friday; the Scotsman on Wednesday and Saturday; the Weekly Journal on Wednesday; and the Weekly Chronicle, the Saturday Evening Post, and the Edinburgh, Leith, and Glasgow Advertiser, a paper solely devoted to advertisements, and distributed gratis, on Saturday.

Public markets.

The public market-day is Wednesday, when there is a large open market held for the sale of cattle, sheep, corn, and other agricultural produce. The spacious street called the Grassmarket is the chief place to which stock is brought for sale. At its western extremity there is a large granary, the lower part of which is open for the exposure of grain in sacks. This edifice was reared in 1819, and is ornamented with a small spire and clock. Once a year, at the beginning of November, there is a large sheep, cattle, and horse market held in the vicinity of the city, called *All Hallow Fair*, being the feast of *All Saints*.

Edinburgh possesses excellent butcher-meat, fish, and vegetable markets. They are situated in the centre of the town, and consist of a series of descending open areas or terraces, connected by flights of steps from the back of the High Street to the bottom of the valley of the North Loch, below the North Bridge. These markets, all the property of the burgh, are exceedingly well supplied with the various articles of consumption for which they are respectively appropriated. There is another market of a similar nature, though on a more limited scale, in Nicolson Street; and a very spacious one, the property of a private individual, near Stockbridge, at the north-west extremity of the New Town.

Coal.

The metropolis is abundantly supplied with coal, chiefly by means of the Union Canal, from pits in the west of Scotland, and by a railway leading from the pits near Dalkeith to its termination at St Leonards. (See EDINBURGHSHIRE.)

Water.

Edinburgh possesses an abundant supply of water from the Crawley Spring in the Pentland Hills. This was effected by a joint-stock company, incorporated by act of parliament in 1819. The cost of laying new pipes, and other matters connected with the introduction of the new springs, amounted to nearly L.200,000. Families are supplied with small service-pipes, by paying to the company a certain duty on their rental.

Lighting.

Edinburgh is lighted with coal gas, manufactured by a joint-stock company associated in 1817, and incorporated in 1818, with a capital of L.100,000, raised by shares of L.25 each. The streets and shops were first illuminated with this brilliant light in 1818. An oil-gas company, instituted in 1826, not having succeeded in its objects, was, after a short trial, incorporated with the coal-gas company.

Burgal system, police, &c.

The ancient civic establishment of Edinburgh was remodelled in 1833 by the act of parliament for reforming the royal burghs of Scotland. It possesses a town council, consisting of thirty-one members chosen by the qualified voters for members of parliament in their respective wards or districts; of a deacon-convener elected by the incorporated trades; and of a dean of guild, chosen by the incorporation of guildry. The council so composed elects a lord provost and four bailies, who compose the magistracy. The magistrates, in virtue of former privileges, hold certain civil and criminal courts, with the assistance of assessors or legal advisers. In 1833 the funds of the civic incorporation were placed under the control of a body of trustees appointed by act of parliament, for the behoof of creditors. In virtue of the act for reforming the system of parliamentary representation, passed in 1832, Edinburgh and its immediate suburbs return two members to parliament.

The merchants of Edinburgh form a body, called the Merchant Company, incorporated by a charter of Charles II. in 1681. It possesses the management of several charitable institutions, and is active in superintending measures connected with the commercial character of the city. Its business is conducted by a master, treasurer, and twelve assistants, and their hall of meeting is a spacious apartment in Hunter Square.

The High Constables are a body of individuals appointed to support the authority of the magistracy, and to assist in maintaining the public peace of the city. They are generally respectable shopkeepers, and are qualified by being burgesses, and having been in business for three years.

Till the year 1805 the city was protected only by a feeble body of old men in the garb of soldiers, entitled the City Guard, the remains of a civic defensive force originally raised in 1514, after the fatal battle of Flodden. In 1805 a regular police establishment was formed, and the city guard was finally dissolved in 1817. The police establishment was remodelled in 1812, and latterly in 1822 and 1832, by acts of parliament each time. The establishment consists of thirty-two general commissioners elected by the inhabitants of the same number of wards, qualified to vote by paying a certain rent. The body of general commissioners is increased by sixteen *ex officio* members, as the provost and magistrates, the sheriffs, and certain other functionaries. Under this body there is an executive police, with a superintendent; and a criminal court is held daily on the plan of that at Bow Street in London, and in which a town bailie officiates as magistrate or judge, in all cases which occur within the ancient and extended royalty; whilst cases originating in that portion of the city included between the exterior limits of the royalty and the general police boundary fall under the cognisance of the sheriff-substitute. Edinburgh is now in all its parts well watched, lighted, and cleaned; and the expenditure for these and other public purposes amounted in the year ending at Whitsunday 1833, to L.31,038. 6s. 6d. An assessment on the inhabitants, of about 1s. 2d. per pound on the rental, supplies the ordinary revenue of the establishment. The head police-office is a large building within a small court near the Cross.

Since the destruction of the old tolbooth, an extensive building, situated on the Calton Hill, fronting the road which sweeps around that eminence, has been provided as the common town and county jail. It was erected in 1817, and is built in a castellated form, in the Saxon style of architecture, after a plan by Mr Archibald Elliot. It is 196 feet in length by forty feet in breadth, and is four stories in height. The interior exhibits a series of corridors opening upon small cells eight feet by six, and forty-eight in number; there is also a chapel on the second floor. This jail at present affords accommodation for debtors, as well as offenders of every description, who are to a certain extent classified, and furnished with airing grounds. A lock-up house, or jail for the confinement of criminals during short periods, adjoins the County Hall in the High Street.

The Bridewell stands adjacent to the jail on the east. It is an edifice of a semicircular form, within an open court, and was constructed in 1791, upon the panopticon principle, after a plan by Mr Robert Adam. The expenses of the establishment are defrayed partly by assessments, and partly by the work of the inmates.

The Canongate Jail is an old-fashioned plain edifice of the time of James VI. It is appropriated exclusively for the incarceration of debtors, and is under the jurisdiction of the magistracy of Canongate.

The public business connected with the civic establishment or corporation is conducted in the Royal Exchange Buildings. The public business of the county, and the sittings of the sheriff and justices, take place in the County Hall, adjacent to the Parliament House. It was erected in 1819, at an expense of L.15,000, but is shortly to be removed in order to make way for the approach by the bridge leading from the Lawnmarket towards the south.

The superiority of the Canongate jurisdiction, which formerly belonged to the abbot of Holyrood, was purchased by the town of Edinburgh from the Earl of Roxburgh, into whose hands it had fallen, in the year 1636. Since that period the burgh of Canongate has been governed by baron bailies appointed by the town council out of their own body, and by two resident bailies, also appointed by the same authority on the recommendation of the baron bailies. In a similar manner bailies are appointed to the subordinate districts of Easter and Wester Portsburgh. Edinburgh has likewise possessed for a long period a superiority over the port of Leith. See Leith.

Population.

In 1755, shortly before the commencement of the New Town, Edinburgh had a population amounting to 57,195; in 1775 it was computed at 70,430; and in 1791 it had risen to about 80,000. In 1801, by parliamentary census, the amount was 82,560; in 1811 it was 102,987; in 1821 it was 138,235; but in these latter enumerations the population of Leith was included. In 1831 the population was as follows:

Parish of Canongate	10,175
College Church	4,244
Greyfriars, Old	4,345
——— New	4,536
High Church	2,614
Lady Yester's	2,890
New North Church	1,350
Old Church	1,952
St Andrew's	7,339
St George's	7,338
St Mary's	6,587
St Stephen's	5,772
Tolbooth	3,256
Tron Church	3,009
St Cuthbert's	70,887
	136,294
North Leith	7,416
South Leith	18,439
Total of Edinburgh and Leith,	162,156[1]

The gross amount of the rental of dwelling-houses, shops, warehouses, &c. producing above five pounds of rent, within the bounds of police, for the year ending at Whitsunday 1833, was L.406,484. The number of householders paying ten pounds of annual rent and upwards, and qualified to vote for members of parliament for the city, in 1832, was 9382. (M. M. M.)

---

[1] There is a slight difference in the amount here stated and the sum of the different parishes added together. It is so in the return.

EDINBURGHSHIRE, or, as it is frequently called, MID LOTHIAN, is the seat of the metropolis of North Britain. It is situated between 55° 39′ and 55° 59′ north latitude, and between 2° 36′ and 3° 33′ longitude west from Greenwich. Its boundaries are the Frith of Forth on the north; Linlithgowshire or West Lothian on the west; the counties of Haddington or East Lothian, Berwick, and Roxburgh on the east; and those of Selkirk, Peebles, and Lanark on the south; the length of the whole line, which is very irregular, and longest on the south, being about ninety miles. The medium length of the county may be taken at twenty-four miles, and the breadth at fifteen; the area thus comprising 360 square miles, or, by the latest computation, 354 square miles, or 226,560 English acres, of which 145,000, or sixty-four acres in a hundred, are in cultivation, and the remainder, or more than a third, hilly, or otherwise comparatively unproductive.

The surface of this county exhibits a great variety of natural scenery, almost everywhere blended and embellished with the labours of taste and opulence. The lower and richer part of it is of a semicircular form, inclining towards the Frith of Forth on the north, and terminating near Mid Calder on the west, and Fala on the south-east, but interrupted by the Pentland Hills, which, rising in the south-west, approach to within five miles of the frith, and thus divide the southern part of this tract into two large plains. These hills cover about forty square miles; and though none of them rise to the height of more than 1700 feet, yet their situation in a flat country, and their bleak and barren aspect, render them very prominent objects in the landscape. On the south-east, where the county terminates almost in a point, between the counties of Roxburgh and Selkirk, and about fifteen miles from the sea, there is another mountainous tract, called the Morefoot Hills, the highest of which rise to upwards of 1800 feet, and extend over fifty square miles. From the rivulet Gala, which flows through it, this is commonly known by the name of the Gala Water district. Fertile valleys are found amongst these hills, and many of the hills themselves have been cultivated. With the exception of these two hilly tracts, Edinburghshire may be considered as a low-lying country, though not level or flat, the surface being varied by ridges and gentle acclivities, and occasionally by detached hills of moderate elevation, amongst which Arthur's Seat, in the vicinity of Edinburgh, and the Corstorphine Hills, are the most considerable. The view from these eminences is singularly rich and beautiful; embracing, besides the city itself, a great many gentlemen's seats, with their pleasure grounds, and elegant villas thickly planted in every direction, with the town and shipping of Leith, and the estuary of the Forth expanding into the ocean on the north and north-east, and the plains and high grounds of Fife beyond; whilst the naked and rugged hills to the south form a striking contrast with the highly-ornamented landscape into which they protrude.

The climate is exceedingly variable, but not subject to extremes. Snow seldom falls before December. From March to June cold east winds often prevail, sometimes attended by great falls of rain. July and August are warm and pleasant. Partly from the nature of the soil, as well as the climate, the corn crops, with a few exceptions, do not come to maturity so soon as in the south of Scotland by three weeks or a month. The fields, in late seasons, are not all cleared, even near the city, till the end of October. According to a register kept in its immediate vicinity for eight years, from 1785 to 1792 inclusive, the average number of rainy days was 175, and the quantity of rain 25·75 inches. The thermometer once in the same period was at 89°, and twice besides above 80°; the lowest point was 11°, and the average of the whole period 46·570.

The streams of this county are so inconsiderable as not to be called rivers, but *waters;* a term which in Scotland is employed to denote a stream somewhat larger than a brook or *burn*, and whose bed is never in ordinary seasons altogether dry. Almond Water, which rises in the borders of Lanarkshire, separates this county from Linlithgowshire for a great part of its course, and falls into the sea near the village of Cramond, where, at high water, it is navigable by sloops for about a quarter of a mile. The Water of Leith has its source in the western extremity of the parish of Currie, on the north side of the Pentland Hills, and falls into the sea at Leith, after a course of about sixteen miles. It flows in a deeper channel than the former; and the banks are, for the most part, beautifully fringed with wood. In no part of the island perhaps is so small a body of water employed with greater effect, there being upwards of seventy mills, the greater number corn mills, on ten miles of its course. The Esk is the most considerable rivulet, and also the most beautiful. It is formed of two others of the same name, called the North Esk and the South Esk. The North Esk rises on the southern side of the Pentland Hills, above Newhall, about fourteen miles from Edinburgh, and flows by Pennicuik, Roslin, Hawthornden, Laswade, and Melville Castle, till it meets with the South Esk below Dalkeith. The South Esk has its source in the Morefoot Hills. On its banks, which are also well wooded and picturesque, stand Arniston, Dalhousie, and Newbattle. Their united streams flow into the sea at Musselburgh. The Tyne, which rises in this county, after a course of five or six miles in a north-east direction, passes into East Lothian; and the Gala, the only rivulet that flows to the south, rising on the north of the Morefoot Hills, leaves this county after it has proceeded about ten miles, and falls into the Tweed below Galashiels. The Esks and the Gala contain trout, and salmon are caught in the Esk at Musselburgh; but the quantity of either is not considerable.

Edinburghshire abounds in coal, limestone, and sandstone, or, as it is popularly called, *freestone.* A continued bed of coal extends across the whole county from Carlops, on the confines of Tweeddale or Peeblesshire, in a direction from south-west to north-east, near fifteen miles in length, and from seven to eight in breadth, on both sides of the North Esk. But it is chiefly towards the lower end of this vale that the coal is wrought, where there are in some places twenty-six seams, from two to ten feet thick. Some of the seams are horizontal, and others almost perpendicular, from which they are distinguished by the names of *flat* seams and *edge* seams; and it has been remarked that the position of the coal corresponds in some degree with the surface of the ground, being level in the valley of the North Esk, and inclined to the horizon on the higher grounds at a distance. Coal has been wrought in the parish of Laswade for upwards of two centuries, where it is still so abundant that the quantity raised is said to be equal to a sixth part of what is obtained from all the coal works of the county. Over nearly the whole coal district it is necessary to keep up powerful steam-engines, for the purpose of freeing the workings from water. A stupendous machine of this description has recently been erected in the parish of Inveresk, by Sir John Hope, Bart. Dikes or veins of stone frequently occur in the coal strata, which, with the expense attending the erection of machinery, and also that incurred in propping the roofs of the pits, forms a very considerable drawback upon the profits realized by the coal-masters. Limestone is found not only in the same tract with the coal, but still farther to the east, and also in the south-west, where coal has not yet been discovered. The great quarry at Gilmerton, in the parish of Libberton, about four miles from Edinburgh, is nearly a mile in length, everywhere open to the light of day, and has the appearance of a long chasm, advancing obliquely to the surface. Like the coal in its neighbourhood, the stone rests in an inclined position, which, when removed, leaves a floor of such a moderate declivity as to be descended by paths among the fragments of rock that have been left. At the bottom there is a pool of water. Overhead is a roof of considerable height, consisting of a bed of solid rock, supported by pillars of limestone. The principal freestone quarries are at Craigleith, in the neighbourhood of the city, from which the six columns in the front of the New College were obtained; and at Hales, in the parish of Colinton, about three miles to the westward. The stone of the former, from its superior whiteness, has been of late most in request for building; but the latter is still unrivalled for flags and for stairs. In the year 1830 a large fossil tree was found in the former quarry, at a considerable depth down in the mass of stone; and another towards the end of October 1833, still deeper. A stone similar to that of Craigleith, but easier wrought, is now got at Redhall, also in the parish of Colinton. Mill-stones have been wrought in the parish of Pennicuik. Copper has been found in the parish of Currie and some other places, but not so rich as to pay for working. Ironstone abounds in the coal district, and also along the shore from Leith westwards; and stones for building and paving are to be found in every parish of the county. A stone similar to the Chinese *Petunse*, used in the manufacture of porcelain, has been found in the Pentland Hills; and clay, fit for being made into crucibles, in the parish of Duddingstone. There are mineral waters in different parts of the county, none of which are of much celebrity, with the exception probably of St Bernard's Well, to the north-west of the city.

The valuation of Edinburghshire, which appears to have been taken in 1649, is L.191,054. 3s. 9d. Scots; and in 1811 the real rent of the lands, according to the returns made under the property-tax, was L.277,827. 19s. 1d. sterling, and of the houses L.400,004. 5s. 6d. In 1795 the landed property was divided into 542 estates, of which twelve belonged to hospitals and other corporate bodies, of the valued rent of L.10,628. 4s. 5d. Scots, or more than an eighteenth part of the whole. Here, as throughout the rest of Scotland, the land is occupied by tenants on leases for a term of years, excepting the comparatively small portion possessed by the proprietors themselves, or let in grass for the season. Within a few miles round the city the cultivation of farms is conducted with a view to the wants of that great market, where potatoes, turnips, and clovers are found more profitable than corn. The price of these crops, sold on the ground, the purchaser taking upon himself all the expense of carrying them to market, or taking them away for his own consumption, may average about L.20 the Scotch acre (about L.16 the English), and very fine crops sometimes bring even more than L.30. Early potatoes, raised within a mile of the city, have been sold, to the extent of several acres on one farm, at L.50 an acre. The manure for raising these crops is amply supplied by the streets and stables of the city. The street soil manure, although the effects of it are not so lasting as those of stable or farm-yard dung, enables the farmers to raise large crops of wheat and other kinds of corn, after the green crops, upon soils that are not naturally very fertile; but the seeds of all sorts with which it abounds are unfavourable to the cleanness of their fields. Their straw, instead of being consumed or converted into manure on their farms, is carried to the city for sale, or given to stablers in exchange for their dung. The rent of farms of from fifty to a hundred acres, within a mile of the city, is in some instances as high as L.8 or L.10 an acre. Lime is very little employed as a manure within the circle to which the town dung extends. Beyond this circle, which has been materially extended by the canal, the system of cultivation is nearly the same as we have already described under other Scotch counties. The extent of the natural wood has been estimated at 3000 acres, and of plantations at about 14,000, being together about one acre in every fourteen.

In 1812, four hundred acres were employed in raising vegetables for the city within a circuit of five miles, and a hundred acres more were under strawberries. Mr Neill, secretary to the Horticultural Society, states the produce of the former at L.45, and the rent from L.8 to L.16 an acre. Between 60,000 and 70,000 Scotch pints of strawberries, or nearly half as many English gallons, are annually sold in Edinburgh, at from 10s. 6d. a pint down to 9d. The produce of an acre is from eight to nine hundred pints, thus yielding a return not very different from the garden grounds. There are also several nurseries in the immediate vicinity of the city, some of them equal to any in the united kingdom for their collection of fruit and forest trees, shrubs, and herbaceous plants, as well as for the arrangement and keeping of the grounds. About a hundred and thirty acres are employed in this way.

The manufactures and commerce of this county, exclusive of Edinburgh, and Leith its sea-port, are inconsiderable. None of the three great branches of industry, the woollen, cotton, or linen manufacture, is carried on here to any extent. Distilleries, paper-mills on both branches of the Esk, iron-works at Cramond, potteries and salt-pans at Inveresk, and gunpowder-works at Stobbs and Roslin, on the South Esk, are the most worthy of notice. The paper-mills of the county have latterly much increased in number, and the article made has become celebrated for its quality. Machinery is employed to a considerable extent in the manufacture of it. From the metropolis of Scotland being situated here, the public roads which pass through it in every direction are kept in the best order, and thus promote its internal trade. A system of railways has lately been constructed between the city and the coal-works to the south-east. By this useful conveyance the metropolis is well supplied with the valuable mineral with which its vicinity abounds. A number of coaches also ply upon the railway, by which a cheap and agreeable conveyance is obtained for ten miles or thereabout to the south-east of the city. A railway between Dalkeith and the port of Leith is in the course of being laid; and it is in contemplation to extend these improvements in land carriage a considerable way farther.

There is a communication between Edinburgh and Glasgow by means of the Union Canal. This work was commenced in 1817, and finished in about five years afterwards. One of the principal objects for which it was projected was to facilitate the conveyance of coal from the coal fields of Falkirk. It has been found of considerable utility in this respect, as also in various others, such as the conveyance of manure from the city into the interior of the country.

Besides the capital itself, there is no town of any note in Edinburghshire, but a great many thriving villages. Of these may be mentioned Mid Calder, Corstorphine, and Cramond, in the north-west; Pennicuik, Dalkeith, which is a burgh of barony, Laswade, Loanhead, and Gilmerton, in the east and south; and Musselburgh, including the villages of Inveresk and Fisherrow, Portobello, and Newhaven, on the Frith of Forth. Portobello is a pleasant village, resembling a portion of the metropolis in elegance, and much resorted to for sea-bathing. Roslin, in the parish of Laswade, is a pleasant village, and much resorted to on account of its castle, a beautiful remnant of antiquity. Dalkeith, the most populous of the places we have mentioned, has been long distinguished for its great weekly markets for meal and grain.

Among the principal seats are, Dalkeith House, Duke of Buccleuch; Newbattle Abbey, Marquis of Lothian; Duddingstone, Marquis of Abercorn; Dalmahoy, Earl of Morton; Dalhousie Castle, Earl of Dalhousie; Melville Castle, Viscount Melville; Calder House, Lord Torphichen; Arniston, Mr Dundas; Pennicuik, Sir George Clerk. To the above may be added the names of some other old families who have long held estates in the county, viz. Borthwick, Craig, Dalrymple, Davidson, Dick, Drummond, Dundas, Forbes, Foulis, Hope, Inglis, Maconochie, Scott, Trotter, Tytler, Watson, and Wauchope.

Edinburghshire sends four members to Parliament, one for the county, two for the city, and one for Leith. The annexed abstract exhibits the state of the population of the county in 1811, 1821, and 1831.

See Robertson's *Survey of Mid Lothian;* the *Statistical Account of Scotland; Beauties of Scotland,* vol. i.; Sir John Sinclair's *General Report of Scotland;* and, for the history and antiquities of the county, Chalmers's *Caledonia,* vol. ii.

EDMONTON, a parish in the county of Middlesex, seven miles from London, on the great north-east road. It is situated in the hundred of the same name, and contains many of the residences of the more wealthy citizens of London. The new river is conducted through it. The population amounted in 1801 to 5993, in 1811 to 7824, in 1821 to 7900, and in 1831 to 8192.

EDOM, or IDUMÆA, in *Ancient Geography,* a district of Arabia Petræa. A great part also of the south of Judæa was called *Idumæa,* because it was occupied by the Idumeans, upon the Jewish captivity, as far as Hebron. But the proper Edom or Idumæa appears not to have been very extensive, from the march of the Israelites, in which they compassed it on the south-eastward, till they came to the country of the Moabites. Within this compass lies Mount Hor, where Aaron died, and marching from which the Israelites fought with King Arad the Canaanite, who came down the wilderness against them. This was the extent of the *Idumæa Propria* to the south of the Dead Sea; but in Solomon's time it extended to the Red Sea. (1 Kings, ix. 26.)

EDRENOS, a town of Asiatic Turkey, in Natolia, situated on a river of the same name, twenty miles south of Bursa.

EDRISI, or ALDRISI, the most eminent of the geographers who have written in the Arabic language. There is no individual of equal eminence over whose life there hangs a deeper veil of mystery, the various parts of it affording rather subjects of controversy to the learned than of precise information to the biographer. The place, and even the country in which he was born, compose the first subject of disputation. Sionita and Hezronita, who published a Latin translation of his work at Paris, make him a Nubian, and gave to their work the title of *Geographia Nubiensis,* the Nubian Geography. They proceeded upon the expression there used, namely, "the Nile of Egypt, which cuts *our* land." Hartmann was at once led to suspect the correctness of this inference, by observing that Nubia was one of the countries of which Edrisi gives the most meagre and imperfect account; and his suspicions were confirmed by learning that Ockley, on examining two manuscripts in the Bodleian Library, had found in both "that land," instead of "*our* land." It seems now generally agreed, therefore, that there is no reason to suppose him of Nubian origin. Others have given him an Egyptian one, which seems more probable, yet rests solely upon the erroneous reading above referred to. In 1663, Bochart stated that he had found in a manuscript of Leo Africanus, that Edrisi was born at Mazara, in Sicily, in 1098. Next year, however, the manuscript was edited by Hottinger, in an appendix to his work entitled *Bibliothecarius Quadripartibus,* when it appeared that the person supposed to be Edrisi was there named Esseriff Essachalli. Esseriff, or Scheriff, is indeed an usual appellation of Edrisi, but it is common to many, and is rather a title than a name. The rest of the name, and the date of birth, are materially different, so that there seems very little reason to doubt that Bochart was here mistaken.

The most positive statement on the subject is that of Casiri, who says (*Bibliotheca Arabico-Hispanica,* ii. 9), that if Edrisi, as appeared probable, were the person designated by the Mahommedan writers under the long appellation of Abu Abdallah Mohamad Ben Mohamad Ben Abdallah Ben Edris, he was born at Septa, or Ceuta, on the coast of Morocco, in the year of the Hegira 493 (A. D. 1099). Casiri not only qualifies his statement with this condition, but he does not state the authorities from which it is derived; so that it rests only upon the confidence reposed in his learning and accuracy. Edrisi was long a mighty name in Northern Africa; but in 919 the dynasty was subverted by Mahedi Abdallah, and the proscribed wrecks of the family, according to D'Herbelot, afterwards sought refuge in Sicily. This certainly tends to strengthen the Sicilian origin of our author, though it is not probable that many would seek refuge by concealment in their native country.

If we may trust the information of Casiri, Edrisi pursued his studies at Cordova, then equally famed as a seat of Moorish empire and a seminary of Arabic learning. From the accurate and particular description he has given of Spain, it is probable that he had travelled through a great part of that country. Various circumstances prove that he removed to Sicily, and began to compose his great work under the patronage, and indeed at the express desire, of Roger II. king of that island. It was completed about the year of the Hegira 548, A. D. 1153.

It has been a subject of pretty warm controversy among the learned whether Edrisi was a Mahommedan or a

Christian. Sionita, who adopts the latter opinion, observes that he repeatedly calls our Saviour the Lord Jesus, and on one occasion simply the Lord, a title which is said never to be applied by Mahommedans unless to Mahommed, while they merely say "Jesus, to whom be peace," or "Jesus, to whom be safety." He also speaks with profound respect of the holy Virgin, and of various saints, using in regard to the latter the Italian expression instead of the Arabic. These arguments are strenuously repelled by Hartmann, though not, as appears to us, on very solid grounds. He justly remarks, indeed, that the Mahommedans speak always with the highest respect of every thing connected with the origin of Christianity. But though this may impair the force of Sionita's arguments, there seems nothing of any importance to place in the opposite scale. Hartmann lays much stress on the circumstance that Edrisi, amongst his numerous names, bears that of Mohamad, which he says was never borne by any Christian; but though this may imply that he was a Mahommedan by birth, it does not authorize us to infer that he may not have become a convert to the opposite faith. He evidently wishes to offend persons of neither profession, and thus writes in a style from which no positive inference can be drawn. But considering how high religious differences ran in that age, it does not appear very probable that he could have resided in Sicily, or been in such high favour with Roger, without adopting the religion of the monarch and country.

The only thing relative to the life of this eminent author which remains even a subject of controversy, is the period of its termination. Bochart has fixed it in the year 1122; but this date clearly proves that he had some quite different person in view; since it appears by the preface to Edrisi's own work, that its completion took place in the year 1153. No other notice, nor even conjecture, relative to the time or manner of his death, is to be found in any author.

From these meagre notices respecting the life of Edrisi, we shall proceed to give some account of his work. It has appeared under various titles. The first and fullest appears to have been, *The going out of a Curious Man to explore the Regions of the Globe, its Provinces, Islands, Cities, and their Dimensions and Situation.* This is sometimes abbreviated into *The going out of a Curious Man to explore the Regions of the Globe;* and sometimes merely *The going out of a Curious Man.* Sionita published it under the name of *Relaxation of the Curious Mind;* but the title of *Nubian Geography,* which he and his companion imposed upon it, though it has become general in Europe, is, as already observed, altogether arbitrary.

The work contains a full description of the whole world, as far as it was known to the author, with its countries, cities, and all its features, physical and political. These are arranged, not according to any of the methods to which we are accustomed, but in a manner peculiar to itself. The world is divided into seven *climates*, commencing at the equinoctial line, and extending northwards to the limit at which the earth is supposed to be rendered uninhabitable by cold. Each climate is then divided by perpendicular lines into eleven equal parts, beginning with the western coast of Africa, and ending with the eastern coast of Asia. The whole world is thus formed into seventy-seven equal square compartments, resembling those upon a chess-board, or those formed upon a plane map, by the intersecting lines of latitude and longitude. The geographer begins with the first part of the first climate, including the western part of Central Africa, and proceeds eastward through the different divisions of this climate, till he finds its termination in the Sea of China. He then returns to the first part of the second climate, and so proceeds till he reaches the eleventh part of the seventh climate, which terminates in the north-eastern extremity of Asia. The inconveniences of such an arrangement must be abundantly obvious. Instead of each country, or at least each region of similar physical character, being described by itself, it is severed by these mechanical sections into fragments, which are described in different and distant parts of the work; and no connected view is given of any great country.

The only valuable unpublished manuscripts of Edrisi which now exist in Europe are two which are preserved in the Bodleian Library. The first, which was brought over from Egypt by Greaves, is written in the Arabic character peculiar to Northern Africa. It is illustrated by a map of the known world, and by thirty-three other maps, containing each part of a climate, so that there are maps only for the first three climates. The second manuscript, brought by Pococke from Syria, is written in the Arabic character, as used in that country, and bears the date of 906 of the Hegira, or A. D. 1500. It consists of 320 leaves, and is illustrated by one general and seventy-seven particular maps, the last consequently including all the parts of every climate. The general map has been published by Dr Vincent in his *Periplus of the Erythræan Sea.*

There is a manuscript (Cod. DLXXX) in the Royal Library at Paris, which professes to be the production of Edrisi; but D'Herbelot, it appears, has not made use of it as such; and De Guignes expresses positive disbelief on the subject. Hartmann, however, found it to coincide in many particulars with the geography of Edrisi. A copy of our author's work was contained at one time in the library of the Escurial, but it was destroyed by a great fire in the year 1671.

The geography of Edrisi, in the original Arabic, was printed at Rome in 1592, at the Medicean press, from a manuscript preserved in the grand-ducal library at Florence. Both the paper and printing are exceedingly neat, the latter being made to resemble manuscript. This unfortunately constitutes the whole merit of the edition, which swarms with typographical errors, and forms, besides, only an epitome of the original work. This epitome seems made, indeed, in the oriental style, by the simple omission of those parts which appeared to the editor to be superfluous; but these comprise many essential and important passages. The description of Mecca, for example, which had been unaccountably omitted, is supplied by Pococke from his manuscript. Hartmann gives instances where reference is made to the description of places of which there occurs no other mention. D'Herbelot and Casiri equally remark the imperfections of this edition; and the information obtained by the writer of this article, at Oxford, as to the result of a comparison between it and the manuscripts in that university, tends entirely to confirm their statements. In most bibliographical works, this impression has been characterized as one of the rarest of books; but Adler, in a visit to Florence, found in the palace there 1129 copies, which were publicly exposed to sale at a moderate rate. If, therefore, the book be wanting, even in many extensive public libraries, it is merely because those libraries have not taken the trouble to procure it.

In 1619, two oriental scholars, Gabriel Sionita and John Hezronita, published at Paris a Latin translation of Edrisi's work, bearing the title, as already observed, of *Geographia Nubiensis.* It is not executed with all that care and accuracy which might have been expected from these learned personages. They have been particularly careless as to the proper names, which are given sometimes in Latin, sometimes in Arabic, sometimes in neither, nor in any intelligible language. In consequence of the Arabic original being occasionally appended, it has been supposed to have been reprinted along with it; but this is a mistake, there being no edition ever printed except the Roman one. George Hieronymus Velschius, an eminent German scholar, had prepared a copy of the Arabic original, with a Latin translation, which he intended to have illustrated with notes; but death prevented the execution of this design, and his manuscript remains deposited in the library of the university of Jena. Casiri (*Bibliotheca Arabico-Hispanica*, ii. 13) mentions that, at the request of many friends, he had determined to re-edit this work, but he appears never to have executed this intention. The part relating to Africa, pre-eminent certainly in point of importance, has been very ably edited by Hartmann, professor of oriental languages at Marburg (Edrisi, *Africa*, Göttingen, 1796). Instead of following the awkward division into climates, he has collected together all the notices relating to each particular country, and has annexed the statements of the countrymen and contemporaries of Edrisi, so that his work forms nearly a complete body of Arabian geography, as far as relates to Africa. (E.)

EDUCATION.

The inquiry, what education ought to be, and the description of what it is, in those communities in which it may be considered as having acquired its greatest improvement, are two subjects which in this work it has been deemed convenient to keep separate. The analytical investigation of the end to which education is directed, and of the means which are available for the attainment of it, is that which is attempted in the present article. What is thought necessary to be said with respect to the other connected topics will be given under the titles National Education, Schools, and Universities.

INTRODUCTION.

Extent of the Subject.—The different Questions which it involves.

The end of education is to render the individual, as much as possible, an instrument of happiness, first to himself, and next to other beings.

The properties by which he is fitted to become an instrument to this end are partly those of the body, and partly those of the mind.

Happiness depends upon the condition of the body, either immediately, as where the bodily powers are exerted for the attainment of some good; or mediately through the mind, as where the condition of the body affects the qualities of the mind.

Education, in the sense in which it is usually taken, and in which it shall here be used, denotes the means which may be employed to render the *mind*, as far as possible, an operative cause of happiness. The mode in which the *body* may be rendered the most fit for operating as an instrument of happiness is generally considered as a different species of inquiry, belonging to physicians and others who study the means of perfecting the bodily powers.

Education, then, in the sense in which we are now using the term, may be defined, the best employment of all the means which can be used by man for rendering the human mind to the greatest possible degree the cause of human happiness. Every thing, therefore, which operates, from the first germ of existence to the final extinction of life, in such a manner as to affect those qualities of the mind on which happiness in any degree depends, comes within the scope of the present inquiry. Not to turn every thing to account is here, if anywhere, bad economy, in the most emphatical sense of the phrase.

The field, it will easily be seen, is exceedingly comprehensive. It is everywhere, among enlightened men, a subject of the deepest complaint, that the business of education is ill performed; and that in this, which, it might have been supposed, would have been considered the most interesting of all human concerns, the practice is far from corresponding with the progress of the human mind. It may be remarked, that, notwithstanding all which has been written on the subject, even the *theory* of education has not kept pace with philosophy; and it is unhappily true, that the *practice* remains to a prodigious distance behind the theory. One reason why the theory or the combination of ideas which the present state of knowledge might afford for improving the business of education, remains so imperfect, probably is, that the writers have taken but a partial view of the subject; in other words, the greater number of them have mistaken a part of it for the whole. And another reason of not less importance is, that they have generally contented themselves with vague ideas of the object or end to which education is required as the means. One grand purpose of the present inquiry will be to obviate all those mistakes; and, if not to exhibit that comprehensive view which we think is desirable, but to which our limits are wholly inadequate, at any rate to conduct the reader into that train of thought which will lead him to observe for himself the boundaries of the subject. If a more accurate conception is formed of the end, a better estimate will be made of what is suitable as the means.

1. It has been remarked, that every thing from the first germ of existence to the final extinction of life, which operates in such a manner as to affect those qualities of the mind on which happiness in any degree depends, comes within the scope of the present inquiry. Those circumstances may be all arranged, according to the hackneyed division, under two heads: they are either physical or moral; meaning by physical, those of a material nature, which operate more immediately upon the material part of our frame; by moral, those of a mental nature, which operate more immediately upon the mental part.

2. In order to know in what manner things operate upon the mind, it is necessary to know how the mind is constructed. *Quicquid recipitur, recipitur ad modum recipientis.* This is the old aphorism, and nowhere more applicable than to the present case. If you attempt to act upon the mind in ways not adapted to its nature, the least evil you incur is to lose your labour.

3. As happiness is the end, and the means ought to be nicely adapted to the end, it is necessary to inquire, what are the qualities of mind which chiefly conduce to happiness, the happiness both of the individual himself and of his fellow-creatures?

Each of these divisions branches itself out into a great number of inquiries. And it is manifest that the complete development of any one of them would require a greater space than we can allow for the whole. It is therefore necessary for us, if we aim at a comprehensive view, to confine ourselves to a skeleton.

The first of these inquiries is the most practical, and, therefore, likely to be the most interesting. Under the physical head it investigates the mode in which the qualities of the mind are affected by the health, the aliment, the air, the labour, &c. to which the individual is subject. Under the moral head it includes what may be called, 1. Domestic education, or the mode in which the mind of the individual is liable to be formed by the conduct of the individuals composing the family in which he is born and bred; 2. technical or scholastic education, including all those exercises upon which the individual is put, as means to the acquisition of habits conducive either to intellectual and moral excellence, or even to the practice of the manual arts; 3. social education, or the mode in which the mind of the individual is acted upon by the nature of the political institutions under which he lives.

The two latter divisions comprehend what is more purely theoretical; and the discussion of them offers fewer attractions to that class of readers, unhappily numerous, to whom intellectual exercises have not by habit been rendered delightful. The inquiries, however, which are included under these divisions, are required as a foundation to those included under the first. The fact is, that good practice can in no case have any solid foundation but in sound theory. This proposition is not more important than it is certain. For what is theory? The *whole* of the knowledge which we possess upon any subject put into that order and form in which it is most easy to draw from it good practical rules. Let any one examine this definition, article by article, and show us that it fails in a single particular. To recommend the separation of practice from theory is, therefore, simply to recommend bad practice.

SECTION I.

Theory of the Human Mind.—Its importance in the Doctrine of Education.

1. The first, then, of the inquiries embraced by the great subject of education is that which regards the nature of the human mind; and the business is, agreeably to the foregoing definition of theory, to put the knowledge which we possess respecting the human mind into that order and form which is most advantageous for drawing from it the practical rules of education. The question is, how the mind, with those properties which it possesses, can, through the operation of certain means, be rendered most conducive to a certain end? To answer this question, the whole of its properties must be known. The whole science of human nature is, therefore, but a branch of the science of education. Nor can education assume its most perfect form till the science of the human mind has reached its highest point of improvement. Even an outline, however, of the philosophy of the human mind would exceed the bounds of the present article; we must, therefore, show what ought to be done, rather than attempt in any degree to execute so extensive a project.

With respect to the human mind, as with respect to every thing else, all that passes with us under the name of knowledge is either matter of experience, or, to carry on the analogy of expression, matter of guess. The first is real knowledge; the properties of the object correspond to it. The latter is supposititious knowledge, and the properties of the object do or do not correspond to it; most likely not. The first thing desirable is, to make an exact separation of those two kinds of knowledge; and, as much as possible, to confine ourselves to the first.

What, then, is it which we experience with regard to the human mind? And what is it which we guess? We have experience of ourselves when we *see*, when we *hear*, when we *taste*, when we *imagine*, when we *fear*, when we *love*, when we *desire*, and so on. And we give names, as above, to distinguish what we experience of ourselves on one of those occasions, from what we experience on another. We have experience of other men exhibiting *signs* of having similar experiences of themselves, that is, of *seeing*, *hearing*, and so on. It is necessary to explain, shortly, what is here meant by a sign. When we ourselves *see*, *hear*, *imagine*, &c. certain actions of ours commonly follow. We know, accordingly, that if any one, observing those actions, were to infer that we had been *seeing*, *hearing*, &c. the inference would be just. As often then as we observe similar actions in other men, we infer that they, too, have been seeing or hearing; and we thus regard the action as the sign.

Having got names to distinguish the state or experience of ourselves when we say, *I see*, *I hear*, *I wish*, and so on, we find occasion for a name which will distinguish the having any (be it what it may) of those experiences, from the being altogether without them; and for this purpose we say *I feel*, which will apply generally to any of the cases in which we say *I see*, or *hear*, or *remember*, or *fear*, and comprehend the meaning of them all. The term *I think* is commonly used for a purpose nearly the same. But it is not quite so comprehensive; there are several things which we should include under the term *our experience of our mind*, to which we should not extend the term *I think*. But there is nothing included under it to which we should not extend the term *I feel*. This is truly, therefore, the generic term.

All our experience, then, of the human mind is confined to the several occasions on which the term *I feel* can be applied. And, now, what does all this experience amount to? What is the knowledge which it affords? It is first a knowledge of the *feelings* themselves; we can remember what, one by one, they were. It is next a knowledge of the order in which they follow one another; and this is all. But this description, though a just one, is so very general as to be little instructive. It is not easy, however, to speak about those feelings minutely and correctly, because the language which we must apply to them is ill adapted to the purpose.

Let us advert to the first branch of this knowledge, that of the feelings themselves. The knowledge of the simple cases may be regarded as easy; the feeling is distinct at the moment of experience, and is distinctly remembered afterwards. But the difficulty is great with the complex cases. It is found that a great number of simple feelings are apt to become so closely united as often to assume the appearance of only one feeling, and to render it extremely difficult to distinguish from one another the simple feelings of which it is composed. And one of the grand questions which divide the philosophers of the present day is, which feelings are simple, and which are complex. There are two sorts which all have regarded as simple; those which we have when we say, I hear, I see, I feel, I taste, I smell, corresponding to the five senses, and the copies of these sensations, called ideas of sense. Of these, the second take place only in consequence of the first; they are, as it were, a revival of them; not the same feelings with the sensations or impressions on the senses, but feelings which bear a certain resemblance to them. Thus, when a man sees the light of noon, the feeling he has is called an *impression*, the impression of light; when he shuts his eyes and has a feeling, the type or relict of the impression, he is not said to *see* the light, or to have the *impression* of light, but to *conceive* the light, or have an idea of it.

These two *impressions*, and their corresponding *ideas*, are simple feelings in the opinion of all philosophers. But there is one set of philosophers who think that these are the only simple feelings, and that all the rest are merely combinations of them. There is another class of philosophers who think that there are original feelings besides impressions and ideas; as those which correspond to the words *remember, believe, judge, space, time,* &c. Of the first are Hartley and his followers in England, Condillac and his followers in France; of the second description are Dr Reid and his followers in this country, Kant and the German school of metaphysicians in general on the Continent.

The determination of this question, namely, what the feelings are, is of very great importance with regard to the second branch of inquiry, namely, what is the order in which those feelings succeed one another. For how can it be known how they succeed one another, if we are ignorant which of them enter into those several groups which form the component parts of the train? It is of vast importance, then, for the business of education, that the analysis of mind should be accurately performed; in other words, that all our complex feelings should be accurately resolved into the simple ones of which they are composed. This, too, is of absolute necessity for the accurate use of language; as the greater number of words are employed to denote those groups of simple feelings which we call complex ideas.

In regard to all events relating to mind or body, our knowledge extends not beyond two points: the first is a knowledge of the events themselves; the second is a knowledge of the order of their succession. The expression in words of the first kind of knowledge is history; the expression of the second is philosophy; and to render that expression short and clear is the ultimate aim of philosophy.

The first steps in ascertaining the order of succession among events are familiar and easy. One occurs, and then another, and after that a third, and so on; but at first it is uncertain whether this order is not merely accidental, and such as may never recur. After a time it is observed, that events, similar to those which have already occurred, are occurring again and again. It is next observed, that they are always followed, too, by the same sort of events by which those events were followed to which they are similar; that these second events are followed, in the third place, by events exactly similar to those which followed the events which they resemble; and that there is thus an endless round of the same sequences.

If the order in which one event follows another were always different, we should know events only one by one, and they would be infinitely too numerous to receive names. If we could observe none but very short sequences; if, for example, we could ascertain that one event was, indeed, always followed by one other of the same description, but could not trace any constancy farther, we should thus know events by sequences of twos and twos. But those sequences would also be a great deal too numerous to receive names.

The history of the human mind informs us, that the sequences which are first observed are short ones. They are still, therefore, too numerous to receive names. But men compound the matter. They give names to sequences which they are most interested in observing, and leave the rest unnamed. When they have occasion to speak of the unnamed successions, they apply to them, the best way they can, the names which they have got; endeavouring to make a partial naming answer an universal purpose. And hence almost all the confusion of language and of thought arises.

The great object, then, is, to ascertain sequences more and more extensive, till, at last, the succession of all events may be reduced to a number of sequences sufficiently small for each of them to receive a name; then, and then only, shall we be able to speak wholly free from confusion.

Language affords an instructive example of this mode of ascertaining sequences. In language the words are as the events. When an ignorant man first hears another speak an unknown language, he hears the sounds one by one, but observes no sequence. At last he gathers a knowledge of the use of a few words, and then he has observed a few sequences; and so he goes on till he understands whatever he hears. The sequences, however, which he has observed, are each of no greater extent than is necessary to understand the meaning of the speaker; they are, by consequence, very numerous and confusing.

Next comes the grammarian; and he, by dividing the words into different kinds, observes that these kinds follow one another in a certain order, and thus ascertains more enlarged sequences, which, by consequence, reduces their number.

Nor is this all; it is afterwards observed, that words consist, some of one syllable, and some of more than one; that all language may thus be resolved into syllables, and that syllables are much less in number than words; that, therefore, the number of sequences in which they can be formed are less in number, and, by consequence, each is more extensive. This is another step in tracing to the most comprehensive sequences the order of succession in that class of events wherein language consists.

It is afterwards observed, that these syllables themselves are compounded; and it is at last found, that they may all be resolved into a small number of elementary sounds corresponding to the simple letters. All language is then found to consist of a limited number of sequences, made up of the different combinations of a few letters.

It is not pretended that the example of language is exactly parallel to the case which it is brought to illustrate. It is sufficient if it aids the reader in seizing the idea which we mean to convey. It shows the analogy between the analyzing of a complex sound, namely, a word, into the simple sounds of which it is composed, to wit, letters; and the analyzing of a complex feeling, such as the idea of a rose, into the simple feelings of sight, of touch, of taste, of smell, of which the complex idea or feeling is made up. It affords, also, a proof of the commanding knowledge which is attained of a train of events, by observing the sequences which are formed of the simplest elements into which they can be resolved; and it thus illustrates the two grand operations, by successful perseverance, in which the knowledge of the human mind is to be perfected.

It is upon a knowledge of the sequences which take place in the human feelings or thoughts, that the structure of education must be reared. And, though much undoubtedly remains to be cleared up, enough is already known of those sequences to manifest the shameful defects of that education with which our supineness, and love of things as they are, rest perfectly satisfied.

As the happiness, which is the end of education, depends upon the actions of the individual, and as all the actions of man are produced by his feelings or thoughts, the business of education is, to make certain feelings or thoughts take place instead of others. The business of education, then, is to work upon the mental successions. As the sequences among the letters or simple elements of speech may be made to assume all the differences between nonsense and the most sublime philosophy, so the sequences in the feelings which constitute human thought, may assume all the differences between the extreme of madness and of wickedness, and the greatest attainable heights of wisdom and virtue; and almost the whole of this is the effect of education. That, at least, all the difference which exists between classes or bodies of men is the effect of education, will, we suppose, without entering into the dispute about individual distinctions, be readily granted; that it is education wholly which constitutes the remarkable difference between the Turk and the Englishman, and even the still more remarkable difference between the most cultivated European and the wildest savage. Whatever is made of any *class* of men, we may then be sure is possible to be made of the whole human race. What a field for exertion! What a prize to be won!

Mr Hobbes, who saw so much farther into the texture of human thought than all who had gone before him, was the first man, as far as we remember, who pointed out (what is peculiarly *knowledge* in this respect) the order in which our feelings succeed one another, as a distinct object of study. He marked, with sufficient clearness, the existence, and the cause of the sequences; but, after a very slight attempt to trace them, he diverged to other inquiries, which had this but indirectly for their object.

"The succession," he says (*Human Nature*, chap. iv.), "of conceptions in the mind, series or consequence" (by *consequence* he means *sequence*), "of one after another, may be casual and incoherent, as in dreams, for the most part; and it may be orderly, as when the former thought introduceth the latter. The cause of the coherence or consequence (*sequence*) of one conception to another, is their first coherence or consequence at that time when they are produced by sense; as, for example, from St Andrew the mind runneth to St Peter, because their names are read together; from St Peter to a stone, for the same cause; from stone to foundation, because we see them together; and, according to this example, the mind may run almost from any thing to any thing. But, as in the sense the conception of cause and effect may succeed one another, so may they, *after* sense, in the imagination." By the succession in the *imagination* it is evident he means the succession of *ideas*, as by the succession in *sense* he means the succession of sensations.

Having said that the conceptions of *cause* and *effect* may succeed one another in the sense, and after sense in the imagination, he adds, "and, for the most part, they do so; the cause whereof is the appetite of them who, having a conception of the *end*, have next unto it a conception of the next *means* to that end; as when a man from a thought of honour, to which he hath an appetite, cometh to the thought of wisdom, which is the next means thereunto; and from thence to the thought of study, which is the next means to wisdom." (*Ibid.*) Here is a declaration with respect to three grand laws in the sequence of our thoughts. The first is, that the succession of ideas follows the same order which takes place in that of the impressions. The second is, that the order of cause and effect is the most common order in the successions in the imagination, that is, in the succession of ideas. And the third is, that the appetites of individuals have a great power over the successions of ideas; as the thought of the object which the individual desires, leads him to the thought of that by which he may attain it.

Mr Locke took notice of the sequence in the train of ideas, or the order in which they follow one another, only for a particular purpose; to explain the intellectual singularities which distinguish particular men. "Some of our ideas," he says, "have a natural correspondence and connection one with another. It is the office and excellence of our reason to trace these, and hold them together in that union and correspondence which is founded in their peculiar beings. Besides this, there is another connection of ideas, wholly owing to chance or custom: ideas that are not at all of kin come to be so united in some men's minds, that it is very hard to separate them; they always keep in company, and the one no sooner at any time comes into the understanding, but its associate appears with it; and if they are more than two which are thus united, the whole gang, always inseparable, show themselves together." There is no attempt here to trace the order of sequence, or to ascertain which antecedents are followed by which consequents; and the accidental rather than the more general phenomena are those which seem particularly to have struck his attention. He gave, however, a name to the matter of fact. When one idea is regularly followed by another, he called this constancy of conjunction *the association of ideas;* and this is the name by which, since the time of Locke, it has been commonly distinguished.

Mr Hume perceived, much more distinctly than any of the philosophers who had gone before him, that to philosophize concerning the human mind was to trace the order of succession among the elementary feelings of the man. He pointed out three great laws or comprehensive sequences, which he thought included the whole. Ideas followed one another, he said, according to *resemblance*, *contiguity* in time and place, and *cause and effect.* The last of these, the sequence according to cause and effect, was very distinctly conceived, and even the cause of it explained, by Mr Hobbes. That of contiguity in time and place is thus satisfactorily explained by Mr Hume. "It is evident," he says, "that as the senses, in changing their objects, are necessitated to change them regularly, and take them as they lie contiguous to each other, the imagination must, by long custom, acquire the same method of thinking, and run along the parts of space and time in conceiving its objects." (*Treatise of Human Nature*, P. i. b. i. sect. 4.) This is a reference to one of the laws pointed out by Hobbes, namely, that the order of succession among the ideas follows the order that took place among the impressions. Mr Hume shows, that the order of sense is much governed by contiguity, and why; and assigns this as a sufficient reason of the order which takes place in the imagination. Of the next sequence, that according to resemblance, he gives no account, and only appeals to the consciousness of his reader for the existence of the fact. Mr Hume further remarked, that what are called our complex ideas are only a particular class of cases belonging to the same law, namely, that of the succession of ideas; every complex idea being only a certain number of simple ideas, which succeed each other so rapidly as not to be separately distinguished without an effort of thought. This was a great discovery; but it must at the same time be owned, that it was very imperfectly developed by Mr Hume. That philosopher proceeded, by aid of these principles, to account for the various phenomena of the human mind. But though he made some brilliant developments, it is nevertheless true, that he did not advance very far in the general object. He was misled by the pursuit of a few surprising and paradoxical results, and when he had arrived at them he stopped.

After him, and at a short interval, appeared two philosophers, who were more sober minded, and had better aims. These were Condillac and Hartley. The first work of Condillac appeared some years before the publication of that of Hartley; but the whole of Hartley's train of thought has so much the air of being his own, that there is abundant reason to believe the speculations of both philosophers equally original. They both began upon the ground that all simple ideas are copies of impressions; that all complex ideas are only simple ideas united by the principle of association. They proceeded to examine all the phenomena of the human mind, and were of opinion that the principle of association, or the succession of one simple idea after another, according to certain laws, accounts for the whole; that these laws might by meditation be ascertained and applied; and that then the human mind would be understood as far as man has the means of knowing it.

The merit of Condillac is very great. It may yet, perhaps, be truer to say that he wrote admirably upon philosophy, than that he was a great philosopher. His power consists in expression; he conveys metaphysical ideas with a union of brevity and clearness which never has been surpassed. But though he professed rather to deliver the opinions of others than to aim at invention, it cannot be denied that he left the science of the human mind in a much better state than he found it; and this is equivalent to discovery. As a teacher, in giving in this field a right turn to the speculations of his countrymen, his value is incalculable; and there is, perhaps, no one, with the exception of Locke, who was his master, to whom in this respect the progress of the human mind is more largely indebted. It is also true, that to form the conception of tracing the sequences among our simple ideas, as comprehending the whole of the philosophy of the human mind, even with the helps which Hume had afforded, and it is more than probable that neither Condillac nor Hartley had ever heard of a work which, according to its author, had fallen dead-born from the press, was philosophical and sagacious in the highest degree.

It must be allowed, however, that, in expounding the various mental phenomena, Condillac does not display the same penetration and force of mind, or the same comprehensiveness, as Dr Hartley. He made great *progress* in showing how those phenomena might be resolved into the sequences of simple ideas; but Dr Hartley made still greater. We do not mean to pronounce a positive opinion either for or against the grand undertaking of Dr Hartley, to resolve the whole of the mental phenomena of man into sequences of impressions, and the simple ideas which are the copies of them. But we have no hesitation in saying, that he philosophizes with extraordinary power and sagacity; and it is astonishing how many of the mental phenomena he has clearly resolved—how little, in truth, he has left about which any doubt can remain.

We cannot afford to pursue this subject any farther. This much is ascertained, that the character of the human mind consists in the sequences of its ideas; that the object of education, therefore, is to provide for the constant production of certain sequences rather than others; and that we cannot be sure of adopting the best means to that end, unless we have the greatest knowledge of the sequences themselves.

In what has been already ascertained on this subject, we have seen that there are two things which have a wonderful power over those sequences. They are custom, and pain and pleasure. These are the grand instruments or powers, by the use of which the purposes of education are to be attained.

Where one idea has followed another a certain number of times, the appearance of the first in the mind is sure to be followed by that of the second, and so on. One of the grand points, then, in the study of education, is to find the means of making, in the most perfect manner, those repetitions on which the beneficial sequences depend.

When we speak of making one idea follow another, and always that which makes part of a good train, instead of one that makes part of a bad train, there is one difficulty, that each idea taken singly by itself is as fit to be a part of a bad train as of a good one; for good trains and bad trains are both made out of the same simple elements. Trains, however, take place by sequences of twos or threes, or any greater number; and the nature of these sequences, as complex parts of a still greater whole, is that which renders the train either salutary or hurtful. Custom is, therefore, to be directed to two points; first, to form those sequences which make the component parts of a good train; and, secondly, to join those sequences together so as to constitute the trains.

When we speak of making one idea follow another, there must always be a starting point; there must be some one idea from which the train begins to flow; and it is pretty evident that much will depend upon this idea. One grand question then is, "What are the ideas which most frequently operate as the commencement of trains?" Knowing what are the ideas which play this important part, we may attach to them by custom such trains as are the most beneficent. It has been observed, that most, if not all, of our trains start from a sensation, or some impression upon the external or internal nerves. The question then is, which are those sensations, or aggregates of sensations, which are of the most frequent recurrence? it being obviously of importance that those which give occasion to the greatest number of trains should be made if possible to give occasion only to the best trains. Now the sensations, or aggregates of sensations, which occur in the ordinary business of life, are those of most frequent recurrence, and from which it is of the greatest importance that beneficial trains should commence. Rising up in the morning and going to bed at night are aggregates of this description common to all mankind; so are the commencement and termination of meals. The practical sagacity of priests, even in the rudest ages of the world, perceived the importance of giving religious trains an ascendency in the mind—of uniting them, by early and steady custom, with those perpetually recurring sensations. The morning and evening prayers, the grace before and after meals, have something correspondent to them in the religion of perhaps all nations.

It may appear, even from these few reflections and illustrations, that if the sensations which are most apt to give commencement to trains of ideas are skilfully selected, and the trains which lead most surely to the happiness, first of the individual himself, and next of his fellow-creatures, are by custom effectually united with them, a provision of unspeakable importance is made for the happiness of the race.

Beside custom, it was remarked by Hobbes, that appetite had a great power over the mental trains. But appetite is the feeling toward pleasure or pain in prospect; that is, future pleasure or pain. To say that appetite, therefore, has power over the mental trains, is to say that the prospect of pleasure or pain has. That this is true every man knows by his own experience. The best means then of applying the prospect of pleasure and pain to render beneficent trains perpetual in the mind, is the discovery to be made, and to be recommended to mankind.

The way in which pleasure and pain affect the trains of the mind is as ends. As a train commences in some present sensation, so it may be conceived as terminating in the idea of some future pleasure or pain. The intermediate ideas between the commencement and the end may be either of the beneficent description or the hurtful. Suppose the sight of a fine equipage to be the commencement, and the riches which afford it the appetite or the end, of a train in the mind of two individuals at the same time. The intermediate ideas in the mind of the one may be beneficent, in the other hurtful. The mind of the one immediately runs over all the honourable and useful modes of acquiring riches, the acquisition of the most rare and useful qualities, the eager watch of all the best opportunities of bringing them into action, and the steady industry with which they may be applied. That of the other recurs to none but the vicious modes of acquiring riches—by lucky accidents, the arts of the adventurer and impostor, by rapine and plunder, perhaps on the largest scale, by all the honours and glories of war. Suppose the one of these trains to be habitual among individuals, the other not; what a difference for mankind!

It is unnecessary to adduce further instances for the elucidation of this part of our mental constitution. What, in this portion of the field, requires to be done for the science of education, appears to be, first, to ascertain what are the ends, the really ultimate objects of human desire; next, what are the most beneficent means of attaining those objects; and, lastly, to accustom the mind to fill up the intermediate space between the present sensation and the ultimate object with nothing but the ideas of those beneficent means. We are perfectly aware that these instructions are far too general. But we hope it will be carried in mind, that little beyond the most general ideas can be embraced in so confined a sketch; and we are not without an expectation that, such as they are, these expositions will not be wholly without their use.

SECTION II.

Qualities of Mind to the Production of which the Business of Education should be directed.

We come now to the second branch of the science of education, or the inquiry, what are the qualities with which it is of most importance that the mind of the individual should be endowed. This inquiry, we are in hopes, the preceding exposition will enable us very materially to abridge. In one sense, it might undoubtedly be affirmed that all the desirable qualities of the human mind are included in those beneficent sequences of which we have spoken above. But as it would require, to make this sufficiently intelligible, a more extensive exposition than we are able to afford, we must content ourselves with the ordinary language, and with a more familiar mode of considering the subject.

That intelligence is one of the qualities in question will not be denied, and may speedily be made to appear. To attain happiness is the object; and, to attain it in the greatest possible degree, all the means to that end which the compass of nature affords must be employed in the most perfect possible manner. But all the means which the compass of nature, or the system in which we are placed, affords, can only be known by the most perfect knowledge of that system. The highest measure of knowledge is therefore required. But mere knowledge is not enough; a mere magazine of remembered facts is a useless treasure. Amid the vast variety of known things, there is needed a power of choosing, a power of discerning which of them are conducive, which not, to the ends which we have in view. The ingredients of intelligence are two, knowledge and sagacity; the one affording the materials upon which the other is to be exerted; the one showing what exists, the other converting it to the greatest use; the one bringing within our ken what is capable and what is not capable of being used as means, the other seizing and combining, at the proper moment, whatever is fittest as means to each particular end. This union, then, of copiousness and energy, this possession of numerous ideas, with the masterly command of them, is one of the more immediate ends to which the business of education is to be directed.

With a view to happiness as the end, another quality will easily present itself as indispensable. Conceive that a man knows the materials which can be employed as means, and is prompt and unerring in the mode of combining them; all this power is lost if there is any thing in his nature which prevents him from using it. If he has any appetite in his nature which leads him to pursue certain things with which the most effectual pursuit of happiness is inconsistent, so far this evil is incurred. A perfect command, then, over a man's appetites and desires, the power of restraining them whenever they lead in a hurtful direction, that possession of himself which insures his judgment against the illusions of the passions, and enables him to pursue constantly what he deliberately approves, is indispensably requisite to enable him to produce the greatest possible quantity of happiness. This is what the ancient philosophers called temperance; not exactly the same with what is called the virtue or grace of temperance, in theological morality, which includes a certain portion (in the doctrines of some theological instructors a very large portion) of abstinence, and not only of abstinence, or the gratuitous renunciation of pleasure, but of the infliction of voluntary pain. This is done with a view to please the god, or object of worship, and to provide, through his favour, for the happiness of a second or future life. The temperance of the ancient philosophers had a view only to the happiness of the present life, and consisted in the power of resisting the immediate propensity, if yielding to it would lead to an overbalance of evil, or prevent the enjoyment of a superior good, in whatever the good or evil of the present life consists. This resisting power consists of two parts; the power of resisting pleasure, and that of resisting pain, the last of which has an appropriate name, and is called fortitude.

These two qualities, the intelligence which can always choose the best possible means, and the strength which overcomes the misguiding propensities, appear to be sufficient for the happiness of the individual himself, to the pursuit of which it cannot be doubted that he always has sufficient motives. But education, we have said, should be an instrument to render the individual the best possible artificer of happiness, not to himself alone, but also to others. What, then, are the qualities with which he ought to be endowed, to make him produce the greatest possible quantity of happiness to others?

It is evident enough to see what is the first grand division. A man can affect the happiness of others, either by abstaining from doing them harm, or by doing them positive good. To abstain from doing them harm receives the name of justice; to do positive good receives that of generosity. Justice and generosity, then, are the two qualities by which man is fitted to promote the happiness of his fellow-creatures. And it thus appears that the four cardinal virtues of the ancients do pretty completely include all the qualities to the possession of which it is desirable that the human mind should be trained. The defect, however, of this description is, that it is far too general. It is evident that the train of mental events which conduct to the proposed results must be far more particularized, to insure, in any considerable degree, the effects of instruction; and it must be confessed that the ethical instructions of the ancients failed by remaining too much in generals. What is wanting is, that the incidents of human life should be skilfully classified; both those on the occasion of which they who are the objects of the good acts are pointed out for the receipt of them, and those on the occasion of which they who are to be the instruments are called upon for the performance. It thus appears that the science of ethics, as well as the science of intellectuals, must be carried to perfection before the best foundation is obtained for the science of education.

SECTION III.

Happiness, the End to which Education is devoted. Wherein it consists not yet determined.

We have spoken of the qualities which are subservient to human happiness as means to an end. But before means can be skilfully adapted to an end, the end must be accurately known. To know how the human mind is to be trained to the promotion of happiness, another inquiry then is necessary: Wherein does human happiness consist? This is a controverted question; and we have introduced it rather with a view to show the place which it occupies in the theory of education, than that we have it in our power to elucidate a subject about which there is so much diversity of opinion, and which some of the disputants lead into very subtle and intricate inquiries. The importance of the question is sufficiently evident from this, that it is the grand central point to which all other questions and inquiries converge; that point by their bearing upon which the value of all other things is determined. That it should remain itself undetermined, implies that this branch of philosophy is yet far from its highest point of perfection.

The speculations on this subject, too, may be divided into two great classes; that of those who trace up all the elements of happiness, as they do all those of intellect, to the simple sensations which, by their transformation into ideas, and afterwards into various combinations, compose, they think, all the intellectual and moral phenomena of our nature; another, that of those who are not satisfied with this humble origin; who affirm that there is something in human happiness, and in the human intellect, which soars high above this corporeal level; that there are intellectual as well as moral forms, the resplendent objects of human desire, which can by no means be resolved into the grosser elements of sense. These philosophers speak of eternal and immutable truths; truths which are altogether independent of our limited experience, which are truly universal, which the mind recognizes without the aid of the senses, and which are the objects of pure intellect. They affirm, also, that there is a notion of right and of wrong wholly underived from human experience, and independent of the laws which regulate, in this world, the happiness and misery of human life; a right and wrong, the distinction between which is perceived, according to some, by a peculiar sense; according to others, by the faculty which discerns pure truth; according to others, by common sense: it is the same, according to some, with the notion of the fitness and unfitness of things; according to others, with the law of nature; according to others, with truth; and there is one eminent philosopher who makes it depend upon sympathy, without determining very clearly whether sympathy depends upon the senses or not.

We cannot too earnestly exhort philosophers to perfect this inquiry, that we may understand at last, not by vague abstract terms, but clearly and precisely, what are the simple ideas included under the term happiness, and what is the real object to which education is pointed; since it is utterly impossible, while there is any vagueness and uncertainty with respect to the end, that there should be the greatest precision and certainty in combining the means.

SECTION IV.

Instruments, and practical Expedients, of Education.

We come at last to the consideration of the means which are at the disposal of man for endowing the human mind with the qualities on which the generation of happiness depends. Under this head the discussion of the practical expedients chiefly occurs; but it also embraces some points of theory. The degree in which the useful qualities of human nature are, or are not, under the powers of education, is one of the most important.

This is the subject of a famous controversy, with names of the highest authority on both sides of the question. Helvetius, it is true, stands almost alone on one side. But Helvetius, alone, is a host. No one man, perhaps, has done so much towards perfecting the *theory* of education as M. Helvetius; and his books are pregnant with information of the highest importance. Whoever wishes to understand the groundwork of education, can do nothing more conducive to his end, than to study profoundly the expositions of this philosophical inquirer, whether he adopts his conclusions, in all their latitude, or not. That Helvetius was not more admired in his own country, is owing really to the value of his work. It was too solid for the frivolous taste of the gay circles of Paris, assemblies of pampered noblesse, who wished for nothing but amusement. That he has been so little valued in this country, is, it must be confessed, owing a little to the same cause; but another has concurred. An opinion has prevailed, a false one, that Helvetius is a peculiarly dangerous enemy to religion; and this has deterred people from reading him; or rather the old people who do not read have deterred the young who do. There is no book, the author of which does not disguise his unbelief, that can be read with more safety to religion. The author attacks nothing but priestcraft, and in one of the worst of its forms; the popish priestcraft of the dark and middle ages; the idea of which we are well accustomed, in this country, to separate from that of religion. When his phraseology at any time extends, and that is not often, to Christianity itself, or to religion in the abstract, there is nothing calculated to reduce; there is nothing epigrammatic and sparkling in the expression, nothing sophistical and artfully veiled in the reasoning; a plain proposition is stated, with a plain indication of its evidence; and if your judgment is not convinced, you are not deluded through the fancy.

M. Helvetius says, that if you take men who bring into the world with them the original constituents of their nature, their mental and bodily frame, in that ordinary state of goodness which is common to the great body of mankind; leaving out of the account the comparatively small number of individuals who come into the world imperfect, and manifestly below the ordinary standard; you may regard the whole of this great mass of mankind as equally susceptible of mental excellence, and may trace the causes which make them to differ. If this be so, the power of education embraces every thing between the lowest stage of intellectual and moral rudeness, and the highest state, not only of actual, but of possible perfection. And if the power of education be so immense, the motive for perfecting it is great beyond expression.

The conclusions of Helvetius were controverted directly by Rousseau; and defended, against the strictures of that writer, by the author himself. We recollect few writers in this country who have embraced them.[1] But our authors have contented themselves rather with rejecting than disproving; and, at best, have supported their rejection only by some incidental reflection, or the indication of a discrepancy between his conclusions and theirs.

---

[1] There is one brilliant authority on the side of Helvetius: "It was a favourite opinion of Sir William Jones, that all men are born with an equal capacity of improvement." Lord Teignmouth's *Life of Sir William Jones*, vol. ii. p. 211.

One of the causes why people have been so much startled by the extent to which Helvetius has carried the dominion of education, seems to us to be their not including in it nearly so much as he does. They include in it little more than what is expressed by the term schooling; commencing about six or seven years of age, and ending at latest with the arrival of manhood. If this alone is meant by education, it is no doubt true that education is far indeed from being all-powerful. But if in education is included every thing which acts upon the being as it comes from the hand of nature, in such a manner as to modify the mind, to render the train of feelings different from what it would otherwise have been; the question is worthy of the most profound consideration. It is probable, that people in general form a very inadequate conception of all the circumstances which act during the first months, perhaps the first moments, of existence, and of the power of those circumstances in giving permanent qualities to the mind. The works of Helvetius would have been invaluable, if they had done nothing more than prove the vast importance of these circumstances, and direct towards them the attention of mankind. Rousseau began this important branch of the study of education. He remarked a variety of important facts, which, till his time, had been almost universally neglected, in the minds of infants, and how much might be done, by those who surround them, to give good or bad qualities to their minds, long before the time at which it had been supposed that education could commence. But Helvetius treated the subject much more profoundly and systematically. He traced the circumstances to the very moment of birth; he showed at how early an age indelible characters may be impressed; nay, that some of the circumstances over which man has a control (for he speaks not of others), circumstances on which effects of the greatest importance depend, may be traced beyond the birth.

It is evident how much it imports the science of education, that these circumstances should, by careful and continued observation, be all ascertained, and placed in the order best adapted for drawing from them the most efficient practical rules. This is of more importance than determining the question, whether the prodigious difference which exists among men ordinarily well organized, is owing wholly to the circumstances which have operated upon them since the first moment of their sensitive existence, or is in part produced by original peculiarities. Enough is ascertained to prove, beyond a doubt, that if education does not perform every thing, there is hardly anything which it does not perform; that nothing can be more fatal than the error of those who relax in the vigilance of education, because nature is powerful, and either renders it impossible for them to accomplish much, or accomplishes a great deal without them; that the feeling is much more conformable to experience, and much more conformable to utility, which ascribes every thing to education, and thus carries the motive for vigilance and industry, in that great concern, to its highest pitch. Thus much, at any rate, is certain, that all the difference which exists, or can ever be made to exist, between one *class* of men and another, is wholly owing to education. Those peculiarities, if any such there be, which sink a man below or elevate him above the ordinary state of aptitude to profit by education, have no operation in the case of large numbers or bodies. But large numbers or bodies of men are raised to a high degree of mental excellence, and might, without doubt, be raised to still higher. Other large bodies, or whole nations, have been found in so very low a mental state, as to be little above the brutes. All this vast distance is undeniably the effect of education. Thus much, therefore, may be affirmed on the side of Helvetius, that a prodigious difference is produced by education; while, on the other hand, it is rather assumed than proved that any difference exists, but that which difference of education creates.

1. *Circumstances of the physical kind which operate upon the Mind in the way of Education.*

The circumstances which are included under the term Education, in the comprehensive sense in which we have defined it, may be divided, we have said, into physical and moral. We shall now consider the two classes in the order in which we have named them; and have here again to remind the reader, that we are limited to the task of pointing out what we should wish to be done, rather than permitted to attempt the performance.

Three things are desirable with regard to the physical circumstances which operate in the way of education favourably or unfavourably; to collect them fully, to appreciate them duly, and to place them in the order which is most favourable for drawing from them practical rules.

This is a service, common to the sciences of education and mind, which has been very imperfectly rendered. It has been chiefly reserved to medical men to observe the physical circumstances which affect the body and mind of man; but of medical men few have been much skilled in the observation of mental phenomena, or have thought themselves called upon to mark the share which physical circumstances had in producing them. There are indeed some, and those remarkable, exceptions. There is Dr Darwin in our own country, and M. Cabanis in France. They have both of them taken the mind as a part at least of their study; and we are highly indebted to them for the number and value of their observations. They are both philosophers in the most important sense of the word; they both observed nature for themselves, observed her attentively, and with their view steadily directed to the proper end. But still it is not safe to rely upon them as guides. They were in too great a haste to establish conclusions, and were apt to let their belief run before their evidence. They were not sufficiently careful to distinguish between the different degrees of evidence, and to mark what is required to constitute proof. To do this steadily seems, indeed, to be one of the rarest of all endowments; and was much less characteristic of the two philosophers we have named, than a wide range of knowledge, from which they collected the facts, and great ingenuity in combining and applying them. Dr Darwin was the most remarkable, both for the strength and the weakness of which we speak. The work of Darwin, to which we chiefly allude, is the *Zoonomia;* though important remarks to the same effect are scattered in his other publications. Cabanis entitled his great work *Rapports du Physique et du Moral de l'Homme.* And there are some works recently announced by German physiologists, the titles of which promise aids in the same endeavour. But though we expect from them new facts and ingenious hints, we have less hope of any great number of sound conclusions.

There are certain general names already in use, including the greater number of the physical circumstances which operate in the way of education upon the mind. It will be convenient, because of their commonness, to make use of them on the present occasion, though neither the enumeration which they make is complete, nor the distribution logical.

All the physical circumstances which operate upon the mind are either, 1. inherent in the body, or, 2. external to the body. Those which are external to the body, operate upon the mind by first operating upon the body.

Of the first kind, the more remarkable seem to be healthiness or sickliness, strength or weakness, beauty or deformity, the temperament, the age, the sex.

Of the second sort, the more remarkable seem to be the aliment, the labour, the air, temperature, action, rest.

Previous to the inquiry concerning the power which physical circumstances exert in the formation of the mind, it may seem that we ought to determine the speculative question respecting the nature of the mind; that is, whether the phenomena of mind may possibly result from a certain organization of matter; or whether something of a different kind, and which we call spiritual, must not be conceived, as the source and origin of thought. We do not mean to enter into this controversy, which would detain us too long. It is not, in the least degree, necessary for the end which we have in view. Whether the one hypothesis, with respect to the mind, be adopted, or the other, the distribution of the circumstances which operate in the formation of human character, into those commonly called physical and those commonly called moral, will be as convenient as any distribution which the present state of our knowledge enables us to make; and all that inquiry can do, in regard to those circumstances, is, to trace them accurately, and to observe their effects; that is, to ascertain what they are, and what the order of the mental events by which they are followed. This is simply matter of experience; and what we experience is the same, whether we adopt one opinion or another with regard to the nature of that which thinks. It is in what we experience, all ascertained, and put into the best possible shape for ease of comprehension, and ready application to practice, that all useful knowledge on this, as on all other subjects, consists.

1. First, we are to consider the circumstances of the body which have an effect upon the mental sequences. The object is, to ascertain which have a tendency to introduce those sequences which are favourable, which to introduce those that are unfavourable, to human happiness, and how to turn this knowledge to account.

Health and sickness, or the states of body which those names most peculiarly express, are the first of the circumstances which we have enumerated under this head. That these states have a tendency to introduce very different trains of thought, is matter of vulgar experience; but very little has been done to examine such trains, and to ascertain what in each is favourable, and what is unfavourable, to human happiness.

We have already seen, that the trains which are favourable to intelligence, temperance, justice, and generosity, are the trains favourable to human happiness. Now, with respect to intelligence, it will be seen that health is partly favourable and partly unfavourable; and the same is the case with sickness. Health is favourable, by allowing that time to be given to study which many kinds of sickness withdraw, and by admitting a more vigorous attention, which the pain and languor of sickness often impair. It is unfavourable, by introducing that flow of pleasurable ideas which is called high spirits, adverse at a certain pitch to the application of attention; and by leading to that passionate pursuit of pleasure, which diminishes, if it does not destroy, the time for study. The mode in which disease operates upon the mental sequences is a subject of great complexity, and in which little has yet been done to mark distinctly the events, and ascertain the order of their succession. Cabanis, in his seventh memoir, entitled *De l'Influence des Maladies sur la Formation des Idées et des Affections Morales*, has made a useful beginning toward the elucidation of this subject; but here, as elsewhere, he is too often general and vague. Instruction may also be gleaned from Darwin; but the facts which bear upon this point rather drop from him incidentally, than are anywhere put together systematically for its elucidation. As they were both physicians, however, of great experience, and of unusual skill in the observation of mental phenomena, their opinions are entitled to the greatest respect. The result of the matter is, that an improved medicine is no trifling branch of the art and science of education. Cabanis accordingly concludes his memoir with the two following propositions:

"1*mo*, L'état de maladie influe d'une manière directe sur la formation des idées et des affections morales: nous avons même pu montrer dans quelques observations particulières, comment cette influence s'exerce.

"2*do*, L'observation et l'expérience nous ayant fait decouvrir les moyens de combattre assez souvent avec succès l'état de maladie, l'art qui met en usage ces moyens, peut donc modifier et perfectionner les opérations de l'intelligence et les habitudes de la volonté."

As it is chiefly through the nervous system, and the centre of that system, the brain, that the mental sequences are affected, and as all the sensitive parts have not an action equally strong, nor equally direct, upon the nerves and brain, diseases affect the mental sequences differently, according to the parts which they invade. The system of the nerves and brain is itself subject to different states of disease. Classified with regard to the functions which that system performs, as the organ of sensibility and of action, these states are thus described by M. Cabanis; "1. excess of sensibility to all impressions on the one part; excessive action on the organs of motion on the other. 2. Unfitness to receive impressions, in sufficient number, or with the due degree of energy; and a diminution of the activity necessary for the production of the motions. 3. A general disturbance of the functions of the system, without any remarkable appearance of either excess or defect. 4. A bad distribution of the cerebral virtue, either when it exerts itself unequally in regard to time, having fits of extraordinary activity, followed by others of considerable remission; or when it is supplied in wrong proportion to the different organs, of which some are to a great degree abandoned, while there appears in others a concentration of sensibility, and of the excitations or powers by which the movements are affected."

The effects upon the mental sequences are represented in the following general sketch, which has the advantage of being tolerably comprehensive, though it is unhappily both vague and confused: "We may lay it down as a general fact, that, in all the marked affections of the nerves, irregularities, less or greater, take place, relative both to the mode in which impressions are received, and to the mode in which the determinations, automatic or voluntary, are formed. On one part, the sensations vary incessantly and rapidly with respect to their vivacity, their energy, and even their number; on another, the strength, the readiness, the facility of action, exhibit the greatest inequalities. Hence perpetual fluctuation, from great excitement to languor, from elevation to dejection; a temper and passions variable in the highest degree. In this condition, the mind is always easily pushed to extremes. Either the man has many ideas, with great mental activity and acuteness, or he is, on the contrary, almost incapable of thinking. It has been well observed, that hypochondriacal persons are by turns both courageous and cowardly; and as the impressions are habitually faulty either by excess or defect, in regard to almost all objects, it is seldom that the images correspond to the reality of things, that the desires and the will obtain the proper force and direction. If, along with these irregularities which arise from the nervous system, should be found a weakness of the muscular organs, or of some important viscus, as, for example, of the stomach, the phenomena, though still analogous in the main, will be distinguished by remarkable peculiarities. During the interval of languor, the debility of the muscles renders the sense of weakness, the fainting and drooping, still more complete and oppressive; life appears ready to escape at every instant. The passions are gloomy, excited by trifles, selfish; the ideas are petty, narrow, and bear only upon the objects of the slightest sensations. At the times of excitation, which arrive the more suddenly the greater the weakness, the muscular determinations do not obey the impulses of the brain, unless by starts, which have neither energy nor duration. These impulses serve only to convince the patient more profoundly of his real imbecility; they give him only a feeling of impatience, of discontent, and anxiety. Desires, often sufficiently keen, but commonly repressed by the habitual feeling of weakness, still more increase the discouraging impression. As the peculiar organ of thought cannot act without the concurrence of several others, and as at that moment it partakes in some degree of the weakness which affects the organs of movement, the ideas present themselves in crowds; they spring up, but do not arrange themselves in order; the necessary attention is not enjoyed; the consequence is, that this activity of the imagination, which we might expect to afford some compensation for the absence of other faculties, becomes a new source of dejection and despair."

In this passage the mental sequences which particular states of disease introduce are clearly shown to have a prodigious influence upon human happiness; but the effects which are produced in respect to intelligence, temperance, generosity, and justice, are mixed up together; and the author rather shows how much this subject deserves to be studied, than gives us information from which any considerable degree of practical utility can be derived. The connection between particular states of body and particular mental trains ought to be carefully watched and recorded. When the events one by one are accurately distinguished, and made easy to be recognized, and when the order in which they follow one another is known, our power over the trains of those events, power to prevent such as are unfavourable, to produce such as are favourable, to human happiness, will then be at its height; and how to take care of his health will be one of the leading parts of the moral and intellectual education of man.

The state of the body with regard to health and disease is the inherent circumstance of the greatest importance, and we must pass over the rest with a cursory notice. The next we mentioned are strength and weakness, meaning chiefly muscular strength and weakness; and the natural, habitual, not the accidental or diseased state. It is a common observation, that muscular strength is apt to withdraw the owner from mental pursuits, and engage him in such as are more of the animal kind; the acquisition and display of physical powers. Few men of great bodily powers have been much distinguished for mental excellence; some of the greatest ornaments of human nature have been remarkable for bodily weakness. Muscular strength is liable to operate unfavourably upon the moral as well as the intellectual trains of thought. It diminishes that respect for other men which is so necessary to resist the impulses of passion; it presents innumerable occasions for playing the tyrant with impunity, and fosters, therefore, all that train of ideas in which the tyrannical vices are engendered. Cabanis remarks, and the fact is worthy of the greatest attention, "Presque tous les grands scélérats sont des hommes d'une structure organique vigoureuse, remarquables par la fermeté et la tenacité de leurs fibres musculaires." It is evident, therefore, how deeply it concerns the happiness of mankind, that the mental trains which this circumstance has a tendency to raise should be accurately known, as thus alone the means can be known, how that which is hurtful may be avoided, that which is useful may be introduced.

Of beauty and deformity, as circumstances affecting the mental trains, much will not be necessary to be said. Illustrations will occur to every body to prove that their power is not inconsiderable; so little, however, has been done to ascertain the facts, and record them in the best possible order, that any thing which deserves the name of knowledge on the subject hardly exists, and the principal service we can render is to point it out for study; to exhort future inquirers to observe diligently the trains which flow from beauty and deformity as their source, and to trace to the largest possible sequences, as above described, the connections which take place between them. Beauty and deformity, it may be observed, operate upon the mental trains in somewhat a different way from health and disease, rather mediately than immediately. It is the idea of their effect upon other people that is the more immediate cause of the trains to which they give occasion. The idea that beauty commands their favourable regards is apt to introduce the well-known trains denoted by the terms vanity, pride, contemptuousness, trains not very favourable to the virtues. The idea that deformity is apt to excite their unfavourable regards, is often observed to lead to acuteness and vigour of intellect, employed as instruments of protection, but to moroseness, and even malignity of temper. The mode, however, in which beauty and deformity operate upon the mental trains, namely, through the idea of their effect upon other people, is common to them with a great many other advantages or disadvantages, which derive their value chiefly from their influence upon other people; and materials for the illustration of this subject have been supplied by various writers upon the human mind.

To the word temperament no very precise idea has hitherto been annexed. It may be conceived in the following manner: The bodily structure, the composition of elements in the body of every individual, is different from that in the body of any other. It is observed, however, that the composition is more nearly resembling in some than in others; that those who thus resemble may be arranged in groups, and that they may all be comprehended in four or five great classes. The circumstances in which their bodily composition agrees, so as to constitute one of those large classes, have been called the temperament, and each of those more remarkable characters of the body has been observed to be attended with a peculiar character in the train of ideas; but the illustration of the trains of ideas, and hence of the qualities of mind, which are apt to be introduced by temperament, and by the diversities of age and of sex, we are obliged, by the rapid absorption of the space allotted to us, wholly to omit. The subject in itself is not very mysterious. Accurate observation and masterly recordation alone are required. To be sure, the same may be said of every object of human inquiry; but in some cases it is not so easy to conceive perfectly what observation and recordation mean. On these topics also we are happy to say that Cabanis really affords very considerable helps.

2. We come now to the second sort of physical circumstances, which have the power of introducing habitually certain trains of ideas, and hence of impressing permanent tendencies on the mind; the circumstances which

are external to the body. Some of these are of very great importance. The first is aliment.

Aliment is good or evil by quality and quantity. Hartley has remarked long ago, that though all the impressions from which ideas are copied are made on the extremities of the nerves which are ramified on the surface of the body, and supply the several organs of sense, other impressions are nevertheless made on the extremities of the nerves which are ramified on the internal parts of our bodies, and that many of those impressions are associated with trains of ideas; that the impressions made upon the extremities of the nerves which are ramified on the alimentary canal, are associated with the greatest number of those trains; and of such trains, that some are favourable to happiness, some altogether the reverse. If the quantity and quality of the aliment be the principal cause of those impressions, here is a physiological reason of the greatest importance for an accurate observation and recordation of the events occurring in this part of the field, what antecedents are attended by what consequents, and what the largest sequences that can be traced. Cabanis confirmed the doctrine of Hartley with regard to the internal impressions, and added another class. He said that not only the extremities of the nerves which terminate internally, but the centre of the nervous influence, the brain itself, received impressions; and that thus there were no fewer than three sources of mental and corporeal movements of man; one external, from which almost all our distinct ideas are copied; and two internal, which exert a very great influence upon the trains of ideas, and hence upon the actions of which these trains are the antecedents or cause.

On this too, as on most of the other topics belonging to the physical branch of education, we must note, as still uncollected, the knowledge which is required. It is understood in a general way, that deep impressions are by this means made upon the mind; but how they are made is a knowledge which, in any such detail and accuracy as to afford useful practical rules, is nearly wanting. There is a passage in Hartley, which we esteem it important to quote: "The sense of feeling may be distinguished into that of the external surface of the body, and that of the cavities of the nose, mouth, fauces, alimentary duct, pelvis, of the kidneys, uterus, bladder of urine, gall bladder, follicles, and ducts of the glands, &c. The sensibility is much greater in the last than in the first, because the impressions can more easily penetrate through the soft epithelium with which the internal cavities are invested. In the mouth and nose this sensibility is so great, and attended with such distinguishing circumstances, as to have the names of taste and smell assigned respectively to the sensations impressed upon the papillæ of those two organs." ......"The taste may also be distinguished into two kinds, viz. the general one, which extends itself to the insides of the lips and cheeks, to the palate, fauces, œsophagus, stomach, and whole alimentary duct, quite down to the anus. ......The pleasures of the taste, considered as extending itself from the mouth through the whole alimentary duct, are very considerable, and frequently repeated; they must, therefore, be one chief means by which pleasurable states are introduced into the brain and nervous system. These pleasurable states must, after some time, leave miniatures of themselves sufficiently strong to be called up upon slight occasions, viz. from a variety of associations with the common visible and audible objects, and to illuminate these and their ideas. When groups of these miniatures have been long and closely connected with particular objects, they coalesce into one complex idea, appearing, however, to be a simple one; and so begin to be transferred upon other objects, and even upon tastes back again, and so on without limits. And, from this way of reasoning, it may now appear that a great part of our intellectual pleasures are ultimately deducible from those of taste; and that one principal final cause of the greatness and constant recurrency of these pleasures, from our first infancy to the extremity of old age, is to introduce and keep up pleasurable states in the brain, and to connect them with foreign objects. The social pleasures seem, in a particular manner, to be derived from this source, since it has been customary in all ages and nations, and is in a manner necessary, that we should enjoy the pleasures of taste in conjunction with our relations, friends, and neighbours. In like manner, nauseous tastes and painful impressions upon the alimentary duct, give rise and strength to mental pains. The most common of these painful impressions is that from excess, and the consequent indigestion. This excites and supports those uneasy states which attend upon melancholy, fear, and sorrow. It appears also to me that these states are introduced in a great degree during sleep, during the frightful dreams, agitations, and oppressions, that excess in diet occasions in the night. These dreams and disorders are often forgotten; but the uneasy states of body which then happen leave vestiges of themselves, which increase in number and strength every day, from the continuance of the cause, till at last they are ready to be called up in crowds upon slight occasions, and the unhappy person is unexpectedly, and at once, as it were, seized with a great degree of the hypochondriac distemper, the obvious cause appearing noways proportionable to the effect; and thus it may appear that there ought to be a great reciprocal influence between the mind and alimentary duct, agreeably to common observation." Cabanis, in like manner, says, "Quoique les médécins aient dit plusieurs choses hazardées, touchant l'effet des substances alimentaires sur les organes de la pensée, ou sur les principes physiques de nos penchans, il n'en est pas moins certain que les différentes causes que nous appliquons journellement à nos corps, pour en renouveller les mouvements, agissent avec une grande efficacité sur nos dispositions morales. On se rend plus propre aux travaux de l'esprit par certaines précautions de régime, par l'usage, ou la suppression de certains alimens. Quelques personnes ont été guéries de violens accès de colère, auxquels elles etoient sujêtes, par la seule diète pythagorique; et dans le cas même où des délires furieux troublent toutes les facultés de l'âme, l'emploi journalier de certaines nourritures ou de certaines boissons, l'impression d'une certaine température de l'air, l'aspect de certains objets, en un mot, un système diététique particulier, suffit souvent pour y ramener le calme, pour faire tout rentrer dans l'ordre primitif."

As it is impossible for us here to attempt a full account of the mode in which aliments operate to produce good or bad effects upon the train of ideas, we shall single out that case which, as operating upon the greatest number of people, is of the greatest importance; we mean that in which effects are produced by the *poverty* of the diet; proposing, under the term poverty, to include both badness of quality and defect of quantity. On badness of quality we shall not spend many words. Aliments are bad in a variety of ways, and to such a degree as to impair the bodily health. Of such the injurious effect will not be disputed. Others, which have in them no hurtful ingredient, may contain so insignificant a portion of nourishment, that to afford it in the requisite degree, they must produce a hurtful distention of the organs. The saw-dust, which some northern nations use for bread, if depended upon for the whole of their nourishment, would doubtless have this effect. The potato, where solely depended upon, is not perhaps altogether free from it. Bad quality, however, is but seldom resorted to, except in consequence of deficient quantity. That is, therefore, the principal point of inquiry.

It is easy to see a great number of ways in which deficient quantity of food operates unfavourably upon the *moral* temper of the mind. As people are ready to sacrifice every thing to the obtaining of a sufficient quantity of food, the want of it implies the most dreadful poverty; that state in which there is scarcely any source of pleasure, and in which almost every moment is subject to pain. It is found by experience, that a human being, almost constantly in pain from his birth, hardly visited by a single pleasure, and almost shut out from hope, loses by degrees all sympathy with his fellow-creatures; contracts even a jealousy of their pleasures, and at last a hatred, and would like to see all the rest of mankind as wretched as himself. If he is habitually wretched, and rarely permitted to taste a pleasure, he snatches it with an avidity, and indulges himself with an intemperance, almost unknown to any other man. The evil of insufficient food acts with an influence not less malignant upon the intellectual than upon the moral part of the human mind. The physiologists account for its influence in this manner. They say, that the signs by which the living energy is manifested may be included generally under the term *irritability*, or the power of being put in action by stimulants. It is not necessary for us to be very particular in explaining these terms; a general conception will for the present suffice. A certain degree of this irritability seems necessary to the proper state, or rather the very existence, of the animal functions. A succession of stimulants of a certain degree of frequency and strength is necessary to preserve that irritability. The most important by far of all the useful stimulants applied to the living organs is food. If this stimulant is applied in less than a sufficient degree, the irritability is diminished in proportion; and all those manifestations of the living energy which depend upon it, mental as well as corporeal, are impaired; the mind loses a corresponding part of its force. We must refer to the philosophical writers on medicine for illustrations and facts, which we have not room to adduce, but which will not be difficult to collect. Dr Crichton places *poor diet* at the head of a list of causes which "weaken attention, and consequently debilitate the whole faculties of the mind."[1] From this fact, about which there is no dispute, the most important consequences arise. It follows, that when we deliberate about the means of introducing intellectual and moral excellence into the minds of the principal portion of the people, one of the first things which we are bound to provide for is a generous and animating diet. The physical causes must go along with the moral; and nature herself forbids that you shall make a wise and virtuous people out of a starving one. Men must be happy themselves before they can rejoice in the happiness of others; they must have a certain vigour of mind, before they can, in the midst of habitual suffering, resist a presented pleasure; their own lives and means of well-being must be worth something, before they can value, so as to respect, the life or well-being of any other person. This or that individual may be an extraordinary individual, and exhibit mental excellence in the midst of wretchedness; but a wretched and excellent people never yet has been seen on the face of the earth. Though far from fond of paradoxical expressions, we are tempted to say that a good diet is a necessary part of a good education; for in one very important sense it is emphatically true. In the great body of the people all education is impotent without it.

Labour is the next of the circumstances in our enumeration. We have distinguished labour from action, though action is the genus of which labour is one of the species; because, of those species, labour is so much the most important. The muscular operations of the body, by which men generally earn their bread, are the chief part of the particulars which we include under that term. The same distinction is useful here as in the former case; labour is apt to be injurious by its *quality* and by its *quantity*. That the quality of the labour in which a man is employed produces effects favourable or unfavourable upon his mind, has long been confessed. Dr Smith made the important remark, that the labour in which the great body of the people are employed, has a tendency to grow less and less favourable as civilization and the arts proceed. The division and subdivision of labour is the principal cause. This confines the attention of the labourer to so small a number of objects, and so narrow a circle of ideas, that the mind receives not that varied exercise, and that portion of aliment, on which almost every degree of mental excellence depends. When the greater part of a man's life is employed in the performance of a few simple operations in one fixed invariable course, all exercise of ingenuity, all adaptation of means to ends, is wholly excluded, and the faculty lost, as far as disuse can destroy the faculties of the mind. The minds, therefore, of the great body of the people are in danger of really degenerating, while the other elements of civilization are advancing, unless care is taken, by means of the other instruments of education, to counteract those effects which the simplification of the manual processes has a tendency to produce.

The *quantity* of labour is another circumstance which deserves attention in estimating the agents which concur in forming the mind. Labour may be to such a degree severe, as to confine the attention almost wholly to the painful ideas which it brings, and to operate upon the mind with nearly the same effects as an habitual deficiency of food. It operates perhaps still more rapidly, obliterating sympathy, inspiring cruelty and intemperance, rendering impossible the reception of ideas, and paralyzing the organs of the mind. The attentive examination, therefore, of the facts of this case, is a matter of first-rate importance. Two things are absolutely certain; that without the bodily labour of the great bulk of mankind, the well-being of the species cannot be obtained: and that if the bodily labour of the great bulk of mankind is carried beyond a certain extent, neither intellect, virtue, nor happiness can flourish upon the earth. What then is that precious middle point, at which the greatest quantity of good is obtained with the smallest quantity of evil, is in this part of the subject the problem to be solved.

The state of defective food and excessive labour is the state in which we find the great bulk of mankind; the state in which they are either constantly existing, or into which they are every moment threatening to fall. These are two, therefore, in settling the rank among the circumstances which concur in determining the degree of intellect and morality capable of being exhibited in the societies of men, which ought to stand in a very eminent place. The mode of increasing to the utmost the quantity of intellect, morality, and happiness in human society, will be very imperfectly understood, till they obtain a new degree of consideration.

We named, besides these, among the physical circumstances which contribute to give permanent characters to the mind, air, temperature, action, and rest. But of these we must leave the illustration wholly to other inquirers. It is mortifying to be obliged to relinquish a subject on which so much depends, and for which so little has been done, with so very imperfect an attempt for its improvement. We shall, however, have performed a service of some utility to education, if what we have said has any tendency to lead men to a juster estimate of the physical circumstances which concur in fashioning the human mind, and hence to greater industry and care in studying and applying them.

---

[1] An Inquiry into the Nature and Origin of Mental Derangement, &c. By A. Crichton, M. D. T. 274.

2. *Circumstances of the moral kind, which operate upon the Mind in the way of Education.*

The moral circumstances which determine the mental trains of the human being, and hence the character of his actions, are of so much importance, that to them the term education has been generally confined; or rather, the term education has been generally used in so narrow a sense, that it embraces only one of the four classes into which we have thought it convenient to distribute the moral circumstances which operate to the formation of the human mind.

1. The first of these classes we have comprehended under the term *Domestic Education.* To this the groundwork of the character of most individuals is almost wholly to be traced. The original features are fabricated here; not indeed in such a manner as to be unsusceptible of alteration, but in such a manner decidedly as to present a good or bad subject for all future means of cultivation. The importance, therefore, of domestic education needs no additional words to explain it, though it is difficult to restrain a sigh when we reflect that it has but now begun to be regarded as within the pale of education; and a few scattered remarks, rather than a full exposition of the subject, is all the information upon it with which the world has been favoured.

By domestic education we denote all that the child hears and sees, more especially all that it is made to suffer or enjoy at the hands of others, and all that it is allowed or constrained to do in the house in which it is born and bred, which we shall consider generally as the parental.

If we consider that the mental trains, as explained above, are that upon which every thing depends, and that the mental trains depend essentially upon those sequences among our sensations which have been so frequently experienced as to create a habit of passing from the idea of the one to that of the other, we shall perceive immediately the reasons of what we have advanced.

It seems to be a law of human nature, that the first sensations experienced produce the greatest effects; more especially that the earliest repetitions of one sensation after another produce the deepest habit; the strongest propensity to pass immediately from the idea of the one to the idea of the other. Common language confirms this law when it speaks of the susceptibility of the tender mind. On this depends the power of those associations which form some of the most interesting phenomena of human life. From what other cause does it arise that the hearing of a musical air, which after a life of absence recalls the parental mansion, produces as it were a revolution in the whole being? That the sympathies between brothers and sisters are what they are? On what other cause originally is the love of country founded; that passionate attachment to the soil, the people, the manners, the woods, the rivers, the hills, with which our infant eyes were familiar, which fed our youthful imaginations, and with the presence of which the pleasures of our early years were habitually conjoined?

It is, then, a fact, that the early sequences to which we are accustomed form the primary habits, and that the primary habits are the fundamental character of the man. The consequence is most important; for it follows that, as soon as the infant, or rather the embryo, begins to feel, the character begins to be formed; and that the habits which are then contracted are the most pervading and operative of all. Education, then, or the care of forming the habits, ought to commence as much as possible with the period of sensation itself; and at no period is its utmost vigilance of greater importance than the first.

Very unconnected, or very general instructions, are all that can be given upon this subject, till the proper decompositions and recompositions are performed; in other words, till the subject is first analysed and then systemized; or, in one word, *philosophized*, if we may use that verb in a passive signification. We can, therefore, do little more than exhort to the prosecution of the inquiry.

The steady conception of the end must guide us to the means. Happiness is the end; and we have circumscribed the inquiry, by naming intelligence, temperance, and benevolence, of which last the two parts are generosity and justice, as the grand qualities of mind through which this end is to be attained. The question then is, how can those early sequences be made to take place on which the habits, conducive to intelligence, temperance, and benevolence are founded; and how can those sequences on which are founded the vices opposite to those virtues be prevented?

Clearness is attained by disentangling complexity; we ought therefore to trace the sequences conducive to each of those qualities in their turn. A part, however, must suffice when we cannot accomplish the whole. Intelligent trains of ideas constitute intelligence. Trains of ideas are intelligent when the sequences in the ideas correspond to the sequences in nature. A man, for example, knows the order of certain words when his idea of the one follows that of the other, in the same order in which the events themselves took place. A man is sagacious in devising means for the production of events when his ideas run easily in trains which are at once agreeable to knowledge, that is, to the trains of events, and at the same time new in the combination. They must be agreeable to knowledge; that is, one of the ideas must follow another in the order in which the objects of which they are the ideas follow one another in nature, otherwise the train would consist of mere chimeras, and, having no connection with things, would be utterly useless. As the event, however, is not in the ordinary course, otherwise sagacity would not be required to give it existence, the ordinary train of antecedents will not suffice; it must be a peculiar train, at once correspondent with nature and adapted to the end. The earliest trains produced in the minds of children should be made to partake as much as possible of those characters. The impressions made upon them should correspond to the great and commanding sequences established among the events on which human happiness principally depends. More explicitly, children ought to be made to see, and hear, and feel, and taste, in the order of the most invariable and most comprehensive sequences, in order that the ideas which correspond to their impressions, and follow the same order of succession, may be an exact transcript of nature, and always lead to just anticipations of events. Especially the pains and pleasures of the infant, the deepest impressions which he receives ought from the first moment of sensation to be made as much as possible to correspond to the real order of nature. The moral procedure of parents is directly the reverse; they strive to defeat the order of nature in accumulating pleasures for their children, and preventing the arrival of pains, when the children's own conduct would have had very different effects.

Not only are the impressions from which ideas are copied, made, by the injudicious conduct of those to whom the destiny of infants is confided, to follow an order very different from the natural one, or that in which the grand sequences among events would naturally produce them; but wrong trains of ideas, trains which have no correspondence with the order of events, are often introduced immediately by words or other signs of the ideas of other men. As we can only give very partial examples of a general error, we may content ourselves with one of the most common. When those who are about children express by their words, or indicate by other signs, that terrific trains of ideas are passing in their minds when they go into the dark; terrific trains, which have nothing to do with the order of events, come up also in the minds of the children in the dark, and often exercise over them an uncontrollable sway during the whole of their lives. This is the grand source of wrong education; to this may be traced the greater proportion of all the evil biases of the human mind. If an order of ideas corresponding with the order of events were taught to come up in the minds of children when they go into the dark, they would think of nothing but the real dangers which are apt to attend it, and the precautions which are proper to be taken; they would have no wrong feelings, and their conduct would be nothing but that which prudence or a right conception of the events would prescribe. If the expressions and other signs of the ideas of those who are about children indicate that trains, accompanied with desire and admiration, pass in their minds when the rich and powerful are named, trains accompanied with aversion and contempt when the weak and the poor, the foundation is laid of a character stained with servility to those above, and tyranny to those below them. If indication is given to children that ideas of disgust, of hatred, and detestation, are passing in the minds of those about them, when particular descriptions of men are thought of, as men of different religions, different countries, or different political parties in the same country, a similar train becomes habitual in the minds of the children, and those antipathies are generated which infuse so much of its bitterness into the cup of human life.

We can afford to say but very few words on the powers of domestic education with regard to temperance. That virtue bears an immediate reference to pain and pleasure. The grand object evidently is, to connect with each pain and pleasure those trains of ideas which, according to the order established among events, tend most effectually to increase the sum of pleasures upon the whole, and diminish that of pains. If the early trains create a habit of over-valuing any pleasure or pain, too much will be sacrificed during life to obtain the one or avoid the other, and the sum of happiness, upon the whole, will be impaired. The order in which children receive their impressions, as well as the order of the trains which they copy from others, has a tendency to create impatience under privation; in other words, to make them in prodigious haste to realize a pleasure as soon as desired, to extinguish a pain as soon as felt. A pleasure, however, can be realized in the best possible manner, or a pain removed, only by certain steps, frequently numerous ones; and if impatience hurries a man to overlook those steps, he may sacrifice more than he gains. The desirable thing would be, that his ideas should always run over those very steps, and none but them; and the skilful use of the powers we have over the impressions and trains of his infancy would lay the strongest foundation for the future happiness of himself, and of all those over whom his actions have any sway. It is by the use of this power that almost every thing is done to create what is called the temper of the individual; to render him irascible on the one hand, or forbearing on the other; severe and unforgiving, or indulgent and placable.

Intelligence and temperance are sometimes spoken of as virtues which have a reference to the happiness of the individual himself, benevolence as a virtue which has a reference to the happiness of others. The truth is, that intelligence and temperance have a reference not less direct to the happiness of others than to that of the possessor; and benevolence cannot be considered as less essential to his happiness than intelligence and temperance. In reality, as the happiness of the individual is bound up with that of his species, that which affects the happiness of the one must also, in general, affect that of the other.

It is not difficult, from the expositions we have already given, to conceive in a general way how sequences may take place in the mind of the infant which are favourable to benevolence, and how sequences may take place which are unfavourable to it. The difficulty is, so to bring forward and exhibit the details, as to afford the best possible instruction for practice. We have several books now in our own language, in particular those of Miss Edgeworth, which afford many finely selected instances, and many detached observations of the greatest value, for the cultivation of benevolence in the infant mind. But the great task of the philosopher, that of *theorizing* the whole, is yet to be performed. What we mean by "theorizing the whole," after the explanations we have already afforded, is not, we should hope, obscure. It is, to observe exactly the facts; to make a perfect collection of them, nothing omitted that is of any importance, nothing included of none; and to record them in that order and form in which all that is best to be done in practice can be most immediately and certainly perceived.

The order of the impressions which are made upon the child by the spontaneous order of events is, to a certain degree, favourable to benevolence. The pleasures of those who are about him are most commonly the cause of pleasure to himself; their pains of pain. When highly pleased, they are commonly more disposed to exert themselves to gratify him. A period of pain or grief in those about him is a period of gloom, a period in which little is done for pleasure, a period in which the pleasures of the child are apt to be overlooked. Trains of pleasurable ideas are thus apt to arise in his mind at the thought of the pleasurable condition of those around him; trains of painful ideas at the thought of the reverse; and he is thus led to have an habitual desire for the one, aversion to the other. But if pleasures, whencesoever derived, of those about him, are apt to be the cause of good to himself, those pleasures which they derive from himself are in a greater degree the cause of good to himself. If those about him are disposed to exert themselves to please him when they are pleased themselves, they are disposed to exert themselves in a much greater degree to please him in particular when it is he who is the cause of the pleasure they enjoy. A train of ideas, in the highest degree pleasurable, may thus habitually pass through his mind at the thought of happiness to others produced by himself; a train of ideas, in the highest degree painful, at the thought of misery to others produced by himself. In this manner the foundation of a life of beneficence is laid.

The business of a skilful education is so to arrange the circumstances by which the child is surrounded, that the impressions made upon him shall be in the order most conducive to this happy result. The impressions, too, which are made originally upon the child, are but one of the causes of the trains which are rendered habitual to him, and which, therefore, obtain a leading influence in his mind. When he is often made to conceive the trains of other men, by the words or other signs by which their feelings are betokened, those borrowed trains become also habitual, and exert a similar influence on the mind. This, then, is another of the instruments of education. When the trains, signified to the child, of the ideas in the minds of those about him, are trains of pleasure at the thought of the happiness of other human beings, trains of the opposite kind at the conception of their misery; and when such trains are still more pleasurable or painful as the happiness or misery is produced by themselves; the association becomes in time sufficiently powerful to govern the life.

The grand object of human desire is a command over the wills of other men. This may be attained either by qualities and acts which excite their love and admiration, or by those which excite their terror. When the education is so wisely conducted as to make the train run habitually from the conception of the good end to the conception of the good means; and as often, too, as the good means are conceived, viz. the useful and beneficial qualities, to make the train run on to the conception of the great reward, the command over the wills of men; an association is formed which impels the man through life to pursue the great object of desire, by fitting himself to be, and by actually becoming, the instrument of the greatest possible benefit to his fellow men.

But, unhappily, a command over the wills of men may be obtained by other means than by doing them good; and these, when a man can command them, are the shortest, the easiest, and the most effectual. These other means are all summed up in a command over the pains of other men. When a command over the wills of other men is pursued by the instrumentality of pain, it leads to all the several degrees of vexation, injustice, cruelty, oppression, and tyranny. It is, in truth, the grand source of all wickedness, of all the evil which man brings upon man. When the education is so deplorably bad as to allow an association to be formed in the mind of the child between the grand object of desire, the command over the wills of other men, and the fears and pains of other men as the means, the foundation is laid of the bad character, the bad son, the bad brother, the bad husband, the bad father, the bad neighbour, the bad magistrate, the bad citizen, to sum up all in one word, the bad man. Yet, true it is, a great part of education is still so conducted as to form that association. The child, while it yet hangs at the breast, is often allowed to find out by experience that crying, and the annoyance which it gives, is that by which chiefly it can command the services of its nurse, and obtain the pleasures which it desires. There is not one child in fifty who has not learned to make its cries and wailings an instrument of power; very often they are an instrument of absolute tyranny. When the evil grows to excess, the vulgar say the child is spoiled. Not only is the child allowed to exert an influence over the wills of others by means of their pains; it finds, that frequently, sometimes most frequently, its own will is needlessly and unduly commanded by the same means, pain, and the fear of pain. All these sensations concur in establishing a firm association between the idea of the grand object of desire, command over the acts of other men, and the idea of pain and terror, as the means of acquiring it. That those who have been subject to tyranny are almost always desirous of being tyrants in their turn; that is to say, that a strong association has been formed in their minds between the ideas of pleasure and dignity on the one hand, and those of the exercise of tyranny on the other, is a matter of old and invariable observation. An anecdote has just been mentioned to us, so much in point, that we will repeat it, as resting on its own probability, though it is hearsay evidence (very good, however, of its kind) on which we have received it. At Eton, in consequence, it is probable, of the criticisms which the press has usefully made upon the system of *fagging* (as it is called) at the public schools, a proposition was lately made among the boys themselves for abolishing it. The idea originated with the elder boys, who were in possession of the power; a power of a very unlimited and formidable description, and by them was warmly supported. It was, however, opposed with still greater vehemence by the junior boys, the boys who were then the victims of it. The expected pleasure of tyrannizing in their turn outweighed the pain of their present slavery. In this case, too, as in most others, the sources of those trains which govern us are two; the impressions made upon ourselves, and the trains which we copy from others. Besides the impressions just recounted, if the trains which pass in the minds of those by whom the child is surrounded, and which he is made to conceive by means of their words and other signs, lead constantly from the idea of command over the wills of other men as the grand object of desire, to the ideas of pain and terror as the means, the repetition of the copied trains increases the effect of the native impressions, and establishes and confirms the maleficent character. These are the few things we can afford to adduce upon the subject of domestic education.

2. In the next place comes that which we have denominated *Technical Education.* To this the term education has been commonly confined; or, rather, the word education has been used in a sense so unhappily restricted, that it has extended only to a part of that which we call technical education. It has not extended to all the arts, but only to those which have been denominated liberal.

The question here occurs, what is the sort of education required for the different classes of society, and what should be the difference in the training provided for each? Before we can treat explicitly of technical education, we must endeavour to show in what manner at least this question ought to be resolved.

There are certain qualities the possession of which is desirable in all classes. There are certain qualities the possession of which is desirable in some, not in others. As far as those qualities extend which ought to be common to all, there ought to be a correspondent training for all. It is only in respect to those qualities which are not desirable in all, that a difference in the mode of training is required.

What then are the qualities the possession of which is desirable in all? They are the qualities which we have already named as chiefly subservient to the happiness of the individual himself and of other men, intelligence, temperance, and benevolence. It is very evident that these qualities are desirable in all men; and if it were possible to get them all in the highest possible degree in all men, so much the more would human nature be exalted.

The chief difficulty respects intelligence; for it will be readily allowed that almost equal care ought to be taken in all classes, of the trains leading to the settled dispositions which the terms temperance and benevolence denote. Benevolence, as we have described it, can hardly be said to be of more importance to the happiness of man in one class than in another. If we bear in mind also the radical meaning of temperance, that is, the steady habit of resisting a present desire for the sake of a greater good, we shall readily grant that it is not less necessary to happiness in one rank of life than in another. It is only necessary to see that temperance, though always the same disposition, is not always exerted on the same objects in the different conditions of life. It is no demand of temperance, in the man who can afford it, to deny himself animal food; it may be an act of temperance in the man whose harder circumstances require that he should limit himself to coarser fare. It is also true, that the trains which lead to temperance and benevolence may be equally cultivated in all classes. The impressions which persons are made to receive, and the trains of others which they are made to copy, may, with equal certainty, be guided to the generating of those two qualities in all the different classes of society. We deem it unnecessary, here indeed it is impossible, to enter into the details of what may be done in the course of technical education, to generate or to confirm the dispositions of temperance and benevolence. It can be nothing more than the application of the principles which we developed, when we endeavoured to show in what manner the circumstances of domestic education might be employed for generating the trains on which these mental qualities depend.

Technical education we shall then consider as having chiefly to do with *intelligence*.

The first question, as we have said before, respects what is desirable for all; the second what is desirable for each of the several classes. Till recently, it was denied that intelligence was a desirable quality in the great body of the people; and as intelligence is power, such is an unavoidable opinion in the breasts of those who think that the human race ought to consist of two classes, one that of the oppressors, another that of the oppressed. The concern which is now felt for the education of the working classes, shows that we have made a great step in knowledge, and in that genuine morality which ever attends it.

The analysis of the ideas decides the whole matter at once. If education be to communicate the art of happiness, and if intelligence consists of two parts, a knowledge of the order of those events of nature on which our pleasures and pains depend, and the sagacity which discovers the best means for the attaining of ends; the question whether the people should be educated, is the same with the question whether they should be happy or miserable. The question whether they should have more or less of intelligence, is merely the question whether they should have more or less of misery, when happiness might be given in its stead. It has been urged that men are by daily experience evinced not to be happy, not to be moral, in proportion to their knowledge. It is a shallow objection. Long ago it was observed by Hume, that knowledge, and its accompaniments, morality and happiness, may not be strictly conjoined in every individual, but that they are infallibly so in every age and in every country. The reason is plain; a natural cause may be hindered of its operation in one particular instance, though in a great variety of instances it is sure to prevail. Besides, there may be a good deal of knowledge in an individual, but not knowledge of the best things. This cannot easily happen in a whole people; neither the whole nor the greater part will miss the right objects of knowledge when knowledge is generally diffused.

As evidence of the vast progress which we have made in right thinking upon this subject, we cannot help remarking, that even Milton and Locke, though both men of great benevolence toward the larger family of mankind, and both men whose sentiments were democratical, yet seem, in their writings on education, to have had in view no education but that of the *gentleman*. It had not presented itself, even to their minds, that education was a blessing in which the indigent orders could be made to partake.

As we strive for an equal degree of justice, an equal degree of temperance, an equal degree of veracity, in the poor as in the rich, so ought we to strive for an equal degree of intelligence, if there were not a preventing cause. It is absolutely necessary for the existence of the human race, that labour should be performed, that food should be produced, and other things provided, which human welfare requires. A large proportion of mankind is required for this labour. Now, then, in regard to all this portion of mankind that labours, only such a portion of time can by them be given to the acquisition of intelligence as can be abstracted from labour. The difference between intelligence and the other qualities desirable in the mind of man is this, that much of time, exclusively devoted to the fixing of the associations on which the other qualities depend, is not necessary; such trains may go on while other things are attended to, and amid the whole of the business of life. The case is to a certain extent the same with intelligence, but to a great extent it is not. Time must be exclusively devoted to the acquisition of it; and there are degrees of command over knowledge to which the whole period of human life is not more than sufficient. There are degrees, therefore, of intelligence, which must be reserved to those who are not obliged to labour.

The question is, and it is a question which none can exceed in importance, what is the degree attainable by the most numerous class? To this we have no doubt it will in time very clearly appear that a most consolatory answer may be given. We have no doubt it will appear that a very high degree is attainable by them. It is now almost universally acknowledged that, on all conceivable accounts, it is desirable that the great body of the people should not be wretchedly poor; that when the people are wretchedly poor, all classes are vicious, all are hateful, and all are unhappy. If so far raised above wretched poverty as to be capable of being virtuous, though it be still necessary for them to earn their bread by the sweat of their brow, they are not bound down to such incessant toil as to have no time for the acquisition of knowledge and the exercise of intellect. Above all, a certain portion of the first years of life are admirably available to this great end. With a view to the productive powers of their very labour, it is desirable that the animal frame should not be devoted to it before a certain age, before it has approached the point of maturity. This holds in regard to the lower animals; a horse is less valuable, less in regard to that very labour for which he is valuable at all, if he is forced upon it too soon. There is an actual loss, therefore, even in productive powers, even in good economy, and in the way of health and strength, if the young of the human species are bound close to labour before they are fifteen or sixteen years of age. But if those years are skilfully employed in the acquisition of knowledge, in rendering all those trains habitual on which intelligence depends, it may be easily shown that a very high degree of intellectual acquirements may be gained; that a firm foundation may be laid for a life of mental action, a life of wisdom, and reflection, and ingenuity, even in those by whom the most ordinary labour will fall to be performed.

Beside the knowledge or faculties which all classes should possess in common, there are branches of knowledge and art which they cannot all acquire, and in respect to which education must undergo a corresponding variety. The apprenticeships, for example, which youths are accustomed to serve to the useful arts, we regard as a branch of their education. Whether these apprenticeships, as they have hitherto been managed, have been good instruments of education, is a question of importance, about which there is now, among enlightened men, hardly any diversity of opinion. When the legislature undertakes to do for every man what every man has abundant motives to do for himself, and better means than the legislature; the legislature takes a very unnecessary, commonly not a very innocent trouble. Into the details, however, of the best mode of teaching, to the working people, the arts by which the different commodities useful or agreeable to man are provided, we cannot possibly enter. We must content ourselves with marking it out as a distinct branch of the subject, and an important object of study.

With respect to the education of that class of society who have wealth and time for the acquisition of the highest measure of intelligence, there is one question to which every body must be prepared with an answer. If it be asked, whether, in the constitution of any establishment for the education of this class; call it university, call it college, school, or any thing else; there ought to be a provision for perpetual improvement, a provision to make the institution keep pace with the human mind; or whether, on the other hand, it ought to be so constituted as that there should not only be no provision for, but a strong spirit of resistance to, all improvement, a passion of adherence to whatever was established in a dark age, and a principle of hatred to those by whom improvement should be proposed; all indifferent men will pronounce that such institution would be a curse rather than a blessing. That he is a *progressive* being, is the grand distinction of man. He is the only progressive being upon this globe. When he is the most rapidly progressive, then he most completely fulfils his destiny. An institution for *education* which is hostile to progression, is, therefore, the most preposterous and vicious thing which the mind of man can conceive.

There are several causes which tend to impair the utility of old and opulent establishments for education. Their love of ease makes them love easy things, if they can derive from them as much credit as they would from others which are more difficult. They endeavour, therefore, to give an artificial value to trifles. Old practices, which have become a hackneyed routine, are commonly easier than improvements; accordingly they oppose improvements, even when it happens that they have no other interest in the preservation of abuses. Hardly is there a part of Europe in which the universities are not recorded in the annals of education as the enemies of all innovation. "A peine la compagnie de Jésus," says d'Alembert, "commençait elle à se montrer en France, qu'elle essuya des difficultés sans nombre pour s'y établir. Les universités surtout firent les plus grands efforts pour écarter ces nouveaux venus. Les Jésuites s'annonçaient pour enseigner gratuitement; ils comptoient déjà parmi eux des hommes savans et célèbres, supérieures peut-être à ceux dont les universités pouvaient se glorifier; l'interêt et la vanité pouvaient donc suffire à leurs adversaires pour chercher les exclure. On se rapelle les contradictions semblables à que les ordres mendians essuyèrent de ces mêmes universités quand ils voulurent s'y introduire; contradictions fondées à peu près sur les mêmes motifs." (*Destruction des Jésuites en France*). The celebrated German philosopher Wolf remarks the aversion of the universities to all improvement, as a notorious fact, derived from adequate motives: "Non adeo impune turbare licet scholarium quietem, et docentibus lucrosam, et discentibus jucundam." (Wolfii *Logica*, Dedic. p. 2.)

But though such and so great are the evil tendencies which are to be guarded against in associated seminaries of education; evil tendencies which are apt to be indefinitely increased when they are united with an ecclesiastical establishment, because, whatever the vices of the ecclesiastical system, the universities have in that case an interest to bend the whole of their force to the support of those vices, and to that end to vitiate the human mind, which can only be rendered the friend of abuses in proportion as it is vitiated intellectually, or morally, or both; it must notwithstanding be confessed, that there are great advantages in putting it in the power of the youth to obtain all the branches of their education in one place, even in assembling a certain number of them together, when the principle of emulation acts with powerful effect; and in carrying on the complicated process according to a regular plan, under a certain degree of discipline, and with the powerful spur of publicity. All this ought not to be rashly sacrificed, nor does there appear to be any insuperable difficulty in devising a plan for the attainment of all those advantages, without the evils which have more or less adhered to all the collegiate establishments which Europe has yet enjoyed.

After the consideration of these questions, we ought next to describe, and prove by analysis, the exercises which would be most conducive in forming those virtues which we include under the name of intelligence. But it is very evident that this is a matter of detail far too extensive for so limited a design as ours. And though, in common language, education means hardly any thing more than making the youth perform those exercises, and a treatise on education means little more than an account of them, we must content ourselves with marking the place which the inquiry would occupy in a complete system, and proceed to offer a few remarks on the two remaining branches of the subject, *Social Education* and *Political Education.*

The branches of moral education heretofore spoken of operate upon the individual in the first period of life, and when he is not as yet his own master. The two just now mentioned operate upon the whole period of life, but more directly and powerfully after the technical education is at an end, and the youth is launched into the world under his own control.

3. *Social Education* is that in which society is the institutor. That the society in which an individual moves produces great effects upon his mode of thinking and acting, every body knows by indubitable experience. The object is, to ascertain the extent of this influence, the mode in which it is brought about, and hence the means of making it operate in a good rather than an evil direction.

The force of this influence springs from two sources; the principle of imitation, and the power of the society over our happiness and misery.

We have already shown, that when, by means of words and other signs of what is passing in the minds of other men, we are made to conceive, step by step, the trains which are governing them, those trains, by repetition, become habitual to our own minds, and exert the same influence over us as those which arise from our own impressions. It is very evident that those trains which are most habitually passing in the minds of all those individuals by whom we are surrounded, must be made to pass with extraordinary frequency through our own minds, and must, unless where extraordinary means are used to prevent them from producing their natural effect, engross to a proportional degree the dominion of our minds. With this slight indication of this source of the power which society usurps over our minds, that is, of the share which it has in our education, we must content ourselves, and pass to the next.

Nothing is more remarkable in human nature than the intense desire which we feel of the favourable regards of mankind. Few men could bear to live under an exclusion from the breast of every human being. It is astonishing how great a portion of all the actions of men are directed to these favourable regards, and to no other object. The greatest princes, the most despotical masters of human destiny, when asked what they aim at by their wars and conquests, would answer, if sincere, as Frederic of Prussia answered, *pour faire parler de soi;* to occupy a large space in the admiration of mankind. What are the ordinary pursuits of wealth and of power, which kindle to such a height the ardour of mankind? Not the mere love of eating and of drinking, or all the physical objects together, which wealth can purchase or power command. With these every man in the long run is easily satisfied. The easy command which those advantages procure over the favourable regards of society; this it is which renders the desire of wealth unbounded, and gives it that irresistible influence which it possesses in directing the human mind.

Whatever, then, are the trains of thought, whatever is the course of action, which most strongly recommends us to the favourable regards of those among whom we live, these we feel the strongest motive to cultivate and display; whatever trains of thought and course of action expose us to their unfavourable regards, these we feel the strongest motives to avoid. These inducements, operating upon us continually, have an irresistible influence in creating habits, and in moulding, that is, educating us, into a character conformable to the society in which we move. This is the general principle; it might be illustrated in detail by many of the most interesting and instructive phenomena of human life; it is an illustration, however, which we cannot pursue.

To what extent the habits and character which those influences tend to produce may engross the man, will no doubt depend, to a certain degree, upon the powers of the domestic and technical education which he has undergone. We may conceive that certain trains might, by the skilful employment of the early years, be rendered so habitual as to be uncontrollable by any habits which the subsequent period of life could induce, and that those trains might be the decisive ones on which intelligent and moral conduct depends. The influence of a vicious and ignorant society would in this case be greatly reduced; but still the actual rewards and punishments which society has to bestow upon those who please and those who displease it, the good and evil which it gives and withholds, are so great, that to adopt the opinions which it approves, to perform the acts which it admires, to acquire the character, in short, which it "delighteth to honour," can seldom fail to be the leading object of those of whom it is composed. And as this potent influence operates upon those who conduct both the domestic education and the technical, it is next to impossible that the trains which are generated, even during the time of their operation, should not fall in with, instead of counteracting, the trains which the social education produces; it is next to impossible, therefore, that the whole man should not take the shape which that influence is calculated to impress upon him.

4. The *Political Education* is the last which we have undertaken to notice of the agents employed in forming the character of man. The importance of this subject has not escaped observation. Some writers have treated of it in a comprehensive and systematical manner, and a still greater number have illustrated it by occasional and striking remarks. It is nevertheless true, that the full and perfect exposition of it yet remains to be made.

The political education is like the key-stone of the arch, the strength of the whole depends upon it. We have seen that the strength of the domestic and the technical education depends almost entirely upon the social. Now it is certain that the nature of the social depends almost entirely upon the political; and the most important part of the physical (that which operates with greatest force upon the greatest number, the state of aliment and labour of the lower classes) is in the long run determined by the action of the political machine. The play, therefore, of the political machine acts immediately upon the mind, and with extraordinary power: but this is not all; it also acts upon almost every thing else by which the character of the mind is apt to be formed.

It is a common observation, that such as is the direction given to the desires and passions of men, such is the character of the men. The direction is given to the desires and passions of men by one thing, and one alone, the means by which the grand objects of desire may be attained. Now this is certain, that the means by which the grand objects of desire may be attained depend almost wholly upon the political machine. When the political machine is such that the grand objects of desire are seen to be the natural prizes of great and virtuous conduct, of high services to mankind, and of the generous and amiable sentiments from which great endeavours in the service of mankind naturally proceed, it is natural to see diffused among mankind a generous ardour in the acquisition of all those admirable qualities which prepare a man for admirable actions, great intelligence, perfect self-command, and over-ruling benevolence. When the political machine is such that the grand objects of desire are seen to be the reward, not of virtue, not of talent, but of subservience to the will, and command over the affections of the ruling few; interest with the *man above* to be the only sure means to the next step in wealth, or power, or consideration, and so on; the means of pleasing the man above become, in that case, the great object of pursuit. And as the favours of the man above are necessarily limited, as some, therefore, of the candidates for his favour can only obtain the objects of their desire by disappointing others, the arts of supplanting rise into importance; and the whole of that tribe of faculties denoted by the words intrigue, flattery, backbiting, treachery, &c. are the fruitful offspring of that political education which government, where the interests of the subject-many are but a secondary object, cannot fail to produce. (A. A. A.)

EDULCORATION properly signifies the rendering substances more mild. Chemical edulcoration consists almost always in taking away acids and other saline substances; and this is effected by washing the bodies to which they adhere in a large quantity of water. The washing of diaphoretic antimony, powder of algaroth, and the like, until the water comes off quite pure and insipid, are instances of chemical edulcoration.

EDWARD, the name of several kings of England. See ENGLAND.

EDWARDS, GEORGE, fellow of the Royal and Antiquarian Societies, was born at Stratford, a hamlet belonging to Westham in Essex, on the 3d of April 1693. After having spent some time at school, he was put as apprentice to a tradesman in Fenchurch Street. His master, who was eminent both for his piety and skill in the languages, treated him with very great kindness; but about the middle of his apprenticeship an accident happened which totally put a stop to the hopes of young Edwards advancing himself in the way of trade. Dr Nicolas, a person of emiwards, orge.

nence in the physical world, and a relation of his master's, happened to die. The doctor's books were removed to an apartment occupied by Edwards, who eagerly employed all his leisure hours, both during the day and great part of the night, in perusing those which treated of natural history, sculpture, painting, astronomy, and antiquities. The reading of these books entirely deprived him of any inclination which he might have formerly had for mercantile business, and he resolved to travel into foreign countries. In 1716 he visited most of the principal towns in Holland, and in about a month returned to England. Two years afterwards he took a voyage to Norway, at the invitation of a gentleman who was disposed to be his friend, and who was nephew to the master of the ship in which he embarked. At this time Charles XII. was besieging Frederickshall, an operation which prevented our young naturalist from making such excursions into the country as he would otherwise have done, for the Swedes were very careful to intercept such strangers as could not give a good account of themselves. But notwithstanding all his precaution he was confined by the Danish guard, who supposed him to be a spy employed by the enemy to procure intelligence of their designs. However, by obtaining testimonials of his innocence, a release was granted. In 1718 he returned to England, and next year he visited Paris by the way of Dieppe. During his stay in France he made two journeys of one hundred miles each, the first to Châlons in Champagne, in May 1720, and the second on foot to Orleans and Blois; but an edict happening at that time to be issued for securing vagrants, in order to transport them to America, as the banks of the Mississippi wanted population, our author narrowly escaped a western voyage. On his arrival in England, Mr Edwards closely pursued his favourite study of natural history, applying himself to drawing and colouring such animals as fell under his notice. In this pursuit he paid a strict attention to natural rather than to picturesque beauty. Birds first engaged his particular attention; and having purchased some of the best pictures of them, he was induced to make a few drawings of his own, which were admired by the curious, who encouraged the young naturalist to proceed, by paying a good price for his early labours. Amongst his first patrons and benefactors may be mentioned Mr James Theobalds of Lambeth, a gentleman zealous for the promotion of science. Being thus unexpectedly encouraged, he increased in skill and assiduity, and, by application to his favourite pursuit, procured a decent subsistence and a large acquaintance. However, he remitted his industry in 1731, when, in company with two of his relations, he made an excursion to Holland and Brabant, where he collected several scarce books and prints, and had an opportunity of examining the original pictures of several great masters at Antwerp, Brussels, Utrecht, and other cities. In December 1733, by the recommendation of Sir Hans Sloane, then president of the College of Physicians, he was chosen librarian to that body, and had apartments assigned him in the college. This office was peculiarly agreeable to his taste and inclination, as he had the opportunity of a constant recourse to a valuable library filled with scarce and curious books on the subject of natural history, which he so assiduously studied. By degrees he became one of the most eminent ornithologists in this or in any other country. His merit in this respect is too well known to render it necessary to pronounce any eulogium on his performances; but it may be observed, that he never trusted to others what he could perform himself, and he often found it so difficult to satisfy his own mind, that he frequently made three or four drawings in order to delineate the object in its most lively character, attitude, and representation. In the year 1743, the first volume of the *History of Birds* was published in quarto. As the number of his subscribers exceeded even his most sanguine expectations, a second volume appeared in 1747. The third volume was published in 1750; and in 1751 appeared the fourth volume. This being the last which he intended to publish at that time, he seems to have considered it as the most perfect of his productions in natural history; and therefore devoutly offered it up to the great God of nature, in humble gratitude for all the good things which he had received from Him in this world. Our author, in 1758, continued his labours under a new title, that of *Gleanings of Natural History*. A second volume of the Gleanings was published in 1760. The third part, which formed the seventh and last volume of his works, appeared in 1764. Thus our author, after a long series of years, the most studious application, and the most extensive correspondence in every quarter of the world, concluded a work which contains engravings and descriptions of more than six hundred subjects in natural history not before described or delineated. He likewise added a general index in French and English, which was afterwards perfected with the Linnæan names, by Linnæus himself, who frequently honoured him with his friendship and correspondence. Some time after Mr Edwards had been appointed librarian to the Royal College of Physicians, he was, on St Andrew's Day, in the year 1750, presented by the president and council of the Royal Society with the gold medal, the donation of Sir Godfrey Copley, annually given on that day to the author of any new discovery in art or nature, in consideration of his natural history just then completed. A copy of this medal he had afterwards engraved, and placed under the title in the first volume of his history. He was a few years afterwards elected fellow of the Royal Society and of the Society of Antiquaries, London, and also a member of many of the academies of sciences and learning in different parts of Europe. In return for these honorary distinctions from learned bodies, he presented elegantly-coloured copies of all his works to the Royal College of Physicians, the Royal Society, the Society of Antiquaries, and to the British Museum; and also to the Academy of Sciences at Paris, from which he received a very polite and obliging letter of thanks by their then secretary M. Defouchy. His collection of drawings, which amounted to upwards of nine hundred, were purchased by the Earl of Bute. They contain a great number of British as well as foreign birds, and other animals hitherto not accurately delineated or described. After the publication of the last work, having arrived at his seventieth year, he found his sight beginning to fail, and his hand losing its wonted steadiness. He retired from public employment to a little house which he had purchased at Plaistow, previously to which he disposed of all the copies as well as plates of his works. The conversation of a few select friends, and the perusal of a few select books, were the amusement of the evening of his life; and now and then he made an excursion to some of the principal cities in England, particularly to Bristol, Bath, Exeter, and Norwich. Some years before his death, the alarming depredation of a cancer, which baffled all the efforts of medical skill, deprived him of the sight of one of his eyes; and he also suffered much from the stone, to which at different periods of his life he had been subject; but in the severest paroxysms of pain he was scarcely known to utter a single complaint. Having completed his eightieth year, emaciated with age and sickness, he died, deservedly lamented, on the 23d of July 1773.

Edwards, Bryan.

Edwards, *Bryan*, the well-known historian of the *West Indies*, was born at Westbury, in Wiltshire, on the 21st of May 1743. His father had a small paternal estate;

but as this did not exceed L.100 per annum, he found it insufficient for the maintenance of a numerous family, and endeavoured to improve his circumstances by dealing in corn and malt. This hazardous trade proved, as it often does, only a means of more deeply involving his affairs; and he died in 1756, leaving a widow and six children in a very distressed situation. Mrs Edwards, however, had two opulent brothers in the West Indies, the eldest of whom, Zachary Bayly, possessing a princely fortune, and being of a very amiable and generous disposition, undertook the support and education of young Edwards. He had already been placed by his father at the school of Mr Foot, a dissenting clergyman at Bristol, where he had been taught the elementary branches of education; but, for some reason which he never was able to divine, that person was strictly prohibited from initiating him in any branches of classical learning. He gave a species of instruction, however, not usual in schools, and from which his pupil probably derived the greatest benefit. He was accustomed to make the boys write letters, or rather essays, on various subjects, such as the beauty and dignity of truth, the obligations to a religious life, the benefits of good education, and the like, giving them, where it appeared necessary, an outline of the arguments which might be employed on the subject. When the papers were given in, he made such observations as appeared proper, insisting at least that they should be correct in point of grammar and orthography. These exercises gave occasion to display the superior talents of Edwards, whose powers of elegant composition already began to appear. He soon became the favourite of his master, who liberally praised these youthful performances, and often transmitted them for the gratification of his parents. They were entirely satisfied; but when the care of his education devolved on his uncle, the agent employed by him at Bristol was much surprised to find an entire deficiency in classical knowledge, and, imputing the blame to the master, removed him immediately to a French boarding school in the same city. It is not said that he acquired here any great portion of Greek and Latin, but he became master of the French language, and having access to an extensive circulating library, cultivated a taste for reading which adhered to him throughout the whole of his future life.

In 1759, another uncle, the younger brother of him under whose care he had hitherto been, arrived in England. He, too, was possessed of an ample fortune, became member of parliament, first for Abingdon, and afterwards for his native town, and set up a splendid establishment in London. He appeared quite disposed to befriend young Edwards, and even took the latter to reside with him; but the nephew observes, that, after enumerating his external advantages, he had nothing else to say in favour of his uncle. What the bad qualities were which drew forth so unfavourable a sentence we are not informed; but in a few months they separated, and Edwards went out to his other uncle. In this friend he seems to have found every thing he could desire; the most enlightened mind, the sweetest temper, and the most generous disposition. To this was added a truly paternal regard for himself, which was returned with all the warmth of filial affection. His uncle, finding him possessed of literary talents, but deficient in classical acquirements, engaged a Mr Teale, a clergyman, and formerly master of a free grammar-school, to reside in his house, and give him the instruction of which he stood in need. This choice proved most acceptable to Edwards; he found in Mr Teale a man of extensive information, and one, too, possessing considerable taste in poetry. He viewed him, therefore, as a companion rather than as a teacher; but this relation between the tutor and pupil, however agreeable to both, was not favourable for instilling the dry principles of grammar and prosody. A much larger proportion of their time was spent in tasting the beauties of Dryden and Pope, and in laughing at the comic sallies of Molière. Mr Edwards, upon the whole, acquired, during this period, small Latin and less Greek; but he continued to practise composition, both in prose and verse; and the two companions sent occasional pieces to the colonial newspapers.

The time was now coming when Mr Edwards' talents were to be exercised in a wider sphere. His uncle dying, bequeathed to him his property; and in 1773 he became heir to the much larger estate of Mr Hume, also of Jamaica. His wealth and talents united, now entitled him to take a lead in the political concerns of the island. In 1784 he published *Thoughts on the Proceedings of Government respecting the Trade of the West India Islands with the United States of America.* This was followed by a speech delivered at a free conference between the Council and Assembly at Jamaica, held on the 25th of November 1789, on the subject of Mr Wilberforce's propositions in the House of Commons concerning the slave trade. It was in 1793, however, that he published his great work, on which he had been many years engaged, entitled *History, Civil and Commercial, of the British Colonies in the West Indies*, 2 vols. 4to. He begins the work by giving a view of the original inhabitants of the West Indies, their manners, institutions, and the means by which they have been so entirely exterminated. This was followed by a sketch of the revolutions through which these islands have passed since the first European invasion. He gives next a geographical and statistical description of each particular island. He treats finally, at great length, of the government, the social state, and above all the commerce, of this remarkable region. In the course of the discussion, he enters fully into its relations with the African coast and the negro slave trade. Mr Edwards, as a great and long-resident proprietor, was almost inevitably led to be a supporter of this traffic. He reasons, however, in a liberal and candid manner on the question, and does not even attempt to deny the extent of the evils with which it was accompanied. He only insists that these evils have been overrated; and that Great Britain, by renouncing it whilst it was still prosecuted by the other nations of Europe, would ruin her own colonies, without doing any thing to improve the condition of the Africans. In 1796 he published, in one volume quarto, a *History of St Domingo*, an island which had excited a deep interest, in consequence of the insurrection of the slaves, and the consequent establishment of an independent negro government. In 1801 a new edition of both these works was published, in three vols. 8vo, under the general title of *History of the West Indies.* A fifth edition issued from the press in the year 1819. When Park returned from his celebrated journey, Mr Edwards, from his oral information, drew up a report of it, which was submitted to the African Society, and published in their *Transactions.* Mr Park afterwards incorporated the greater part of this into the general narrative of his *Travels*, in preparing which he availed himself much of the assistance and suggestions of Mr Edwards. It has been currently said that this narrative was entirely written by Mr Edwards; but as this assertion has been pointedly contradicted by Park, who has elsewhere shown respectable talents for composition, it can only be understood in the limited sense which has now been stated. It appears, however, that Mr Park was induced, by Mr Edwards' influence, to give rather a more favourable view of the trade in slaves than reflection afterwards led him to sanction.

Mr Edwards, after his removal to England, took up his residence at Polygon, near Southampton; and in 1796 he became member of parliament for the borough of Grampound, which he continued to represent till his death, which took place on the 15th of July 1800. He left a short narrative of his life, which was prefixed to the edition of his history published in 1801. (E.)

Edwards, *Jonathan*, a celebrated American metaphysician and divine, was born on the 5th of October 1703, at Windsor, in the province of Connecticut. His family had originally emigrated from England in the reign of Queen Elizabeth. His father, Mr Timothy Edwards, was a clergyman of great piety and respectability, and by his mother he was grandson of Mr Solomon Stoddard, a noted and zealous divine of Northampton. Jonathan was accordingly reared in the bosom of Puritanism, and all his ideas were early imbued with the cast of thought which was native to the stock from which he had sprung. There was something indeed not a little singular in the prevailing character of religion in America in those days. A conversion seems to have been a regular era in a man's life, which could be fixed down to a date, as much as his coming of age or his being married. A very curious document remains of Jonathan's conversion, the whole steps and progress of which he has detailed for the behoof of his children; and it is a document which, even amidst all its frequent weakness and extravagance, impresses us with a high sense of the genius and of the worth of this remarkable man. We cannot avoid giving our readers a little insight into it, especially as it contains some passages of deep feeling and sensibility, which form a striking contrast to the controversial hardness of his other writings. It is full of bursts of tenderness; and even whilst the subjects of his earliest meditations were the same dark doctrines, in their most tremendous form, which he afterwards defended so ably by the help of his mature reason, amidst all the gloom which naturally surrounds them, they seem to have left upon his mind no sentiments but those of gentleness and charity. At the same time, this document affords us a distinct proof that such doctrines take their origin, in a great measure, in peculiar circumstances of society, or of the individual mind; and since they were quite as fully impressed upon Edwards before he was capable of any profound reasoning concerning them, as afterwards, the presumption is, that his early prepossessions came strongly in aid of his later conclusions.

It was in the midst of these youthful musings that he acquired a full and firm persuasion of tenets which we will own scarcely seem to us to be either so lovely, or of so good report, as the more natural sentiments of his unconverted state, which he gave up in exchange for them. "I had a variety," says he "of concerns and exercises about my soul from my childhood; but had two more remarkable seasons of awakening before I met with that change by which I was brought to those new dispositions, and that new sense of things, that I have since had. The first time was when I was a boy, some years before I went to college, at a time of remarkable awakening in my father's congregation. I was then very much affected for many months, and concerned about the things of religion." This state of mind, however, appears to have passed off; but, in his last year at college, he was visited by a severe sickness, which made him form many wise and holy resolutions, which he was afterwards for the most part enabled to keep. So far it was well; but now follows the grand proof of his conversion. "From my childhood up," he says, "my mind had been wont to be full of objections against the doctrine of God's sovereignty in choosing whom he would to eternal life, and rejecting whom he pleased, leaving them eternally to perish, and be everlastingly tormented in hell. It used to appear like a horrible doctrine to me. But I remember very well when I seemed to be convinced and fully satisfied as to this sovereignty of God, and his justice in thus eternally disposing of men according to his sovereign pleasure. But I never could give an account how or by what means I was thus convinced, not in the least imagining in the time of it, nor a long time after, that there was any extraordinary influence of God's Spirit in it, but only that now I saw farther, and my reason apprehended the justice and reasonableness of it. However, my mind rested in it, and it put an end to all those cavils and objections that had till then abode with me all the preceding part of my life. And there has been a wonderful alteration in my mind with respect to God's sovereignty from that day to this, so that I scarce ever have found so much as the rising of an objection against God's sovereignty in the most absolute sense, in showing mercy to whom he will show mercy, and hardening and eternally damning whom he will. God's absolute sovereignty and justice, with respect to salvation and damnation, is what my mind seems to rest assured of as much as of any thing that I see with my eyes." This doctrine continued throughout Mr Edwards' life in peculiar favour with him; and he employs the whole resources of his dialectics to support it, with a full conviction that he was thereby glorifying God, and performing an important service to mankind.

In this document of Mr Edwards' early opinions, we have said that, amidst all the horrors of his creed, there are many intimations of the natural fineness and sensibility of his spirit. The following passages are remarkably beautiful, and have about them a tone of pastoral or rather scriptural poetry. "Not long after I first began to experience these things, I gave an account to my father of some things that had passed in my mind. I was pretty much affected by the discourse we had together; and when the discourse was ended, I walked abroad alone in a solitary place in my father's pasture for contemplation. And as I was walking there, and looked up on the sky and clouds, there came into my mind so sweet a sense of the glorious majesty and grace of God that I know not how to express it....God's excellency, his wisdom, his purity and love, seemed to appear in every thing; in the sun, moon, and stars; in the clouds and blue sky; in the grass, flowers, trees; in the water and all nature, which used greatly to fix my mind. I often used to sit and view the moon for a long time, and so in the day time spent much time in viewing the clouds and sky, to behold the sweet glory of God in these things; in the mean time singing forth with a loud voice my contemplations of the Creator and Redeemer...I used to be a person uncommonly terrified with thunder; and it used to strike me with terror when I saw a thunder-storm rising; but now, on the contrary, it rejoiced me. I felt God at the first appearance of a thunder-storm, and used to take an opportunity at such times to fix myself to view the clouds, and see the lightnings play, and hear the majestic and awful voice of God's thunder." These confessions have let us already into the inside of Edwards' mind, and there is no need to return upon them whilst we pursue the account of his studies, life, and writings. There is a poetry and grandeur in some of his passages of this sort which show a moral sublimity of genius in the midst of enthusiastic reveries, often, in inferior minds, more productive of dark and disorderly sentiments than of sound and elevated piety. When he comes, however, to reason on his theological or philosophical tenets, he is no longer either an enthusiast or a poet; for he then proceeds with all the pertinacity and ingenuity of a hard-headed dialectician, determined neither to tolerate nor employ any weapon but stern argument.

He went young to Yale College, and as early as his thirteenth year had read Locke *On the Human Under-*

standing with great delight and profit. He had a great taste for natural philosophy, but the moral and divine sciences were his chief object; and after a long residence at college, during which time he prepared himself assiduously for the ministry, he was in due form licensed to preach. In August 1722 he was invited to preach to the English Presbyterians at New York, where he continued with approbation above eight months; but as this society was too small to maintain a preacher, he returned in the year 1723 to his father's house at Connecticut, where, for some time, he applied to his studies with much industry and perseverance; and this severe application became habitual to him, although he was of a delicate constitution. In the spring of 1724, having taken his master's degree, he was appointed tutor of Yale College, being then in his twenty-first year; an office which, notwithstanding his youth, he filled for two years with great success and reputation. In September 1726 he received an invitation from the people of Northampton in Connecticut, to become assistant to his mother's father, Mr Stoddard, to whom he was ordained colleague in his twenty-fourth year, and continued as pastor of this congregation till the year 1750. During this time he married, had many children, and wrote several pious and useful treatises, chiefly suggested by the events of the times, such as his *Faithful Narrative of the Surprising Work of God, in the Conversion of many Hundred Souls in Northampton* (for these, as his biographer[1] tells us, were remarkable times for the out-pouring of God's Spirit); but particularly a sensible and useful treatise on *Religious Affections*, in which he endeavoured to restrain the extravagance and fanaticism into which, under these strong impressions, the religion of his flock was but too apt to degenerate. He was a most faithful and conscientious minister, but at last fell under the displeasure of his people, from no other cause except his anxiety for their spiritual interests. They appear, indeed, to have been a very stiff-necked generation, full of absurd whimsical vagaries on the subject of religion, but at the same time evincing little of its spirit in their lives and conversations. They had all a voice in the election and continuance of their clergyman, and they were very ready to seize any opportunity to show their power. Mr Edwards discovered that some licentious books had got among the youth of his congregation, a fact as to which he wished some investigation to take place; and this was the first point upon which his people flew off from him. There arose afterwards another point about the administration of the holy communion. His grandfather Mr Stoddard had, it seems, a notion that the administration of the sacrament was a moment which the Divine Spirit was much disposed to seize for the conversion of sinners; and that, therefore, the most notorious sinners were almost without scruple to be admitted to that holy ordinance, in the hope that this conversion would fall upon them. The result of this precious notion was, that the utmost licentiousness, mingled as it was with wild religious fancies floating in every brain, began to prevail amongst the people. When Mr Edwards, on his grandfather's death, obtained the entire charge, he endeavoured to make a change in this particular; but the outcry against him was loud and overbearing. Even his brethren of the clergy tamely gave way to a clamour which they condemned; and this excellent, able, and pious clergyman was thus driven away by the misguided flock, for whom he had laboured assiduously during twenty-four years; and at an advanced period of life, with a wife and a large family, he was thrown upon the world and the care of providence.

His next position was at Stockbridge, in the western part of Massachusetts Bay, where he was put at the head of a mission for converting the Indians. He was not enabled to do much as a missionary; but here he had a great deal of leisure, which he employed in writing his principal works. It was now he completed his chief treatise on the subject of free will; a work concerning the rapid execution of which we have the following information in Sir Henry Moncreiff Wellwood's able and interesting *Life of Dr Erskine*. "It was not till the month of July 1752, that he appears to have resumed his studies on the subject of free will; for on the 7th of that month he writes Dr Erskine, that 'he hoped soon to be at leisure to resume his design;' and gives him another sketch of the plan of his book, in which, though there be nothing new, there is more detail than in that which he had formerly sent him. Whatever opinion," continues this able writer, "may be held with regard to Mr Edwards' argument, it must appear astonishing to those who are capable of appreciating the difficulty of his subject, that, in nine months from the date of this letter, on the 14th of April 1753, he could write Dr Erskine, that he had almost finished the first draught of what he originally intended; though he was under the necessity of delaying the publication till he knew the result of proposals which he had circulated for printing his book by subscription. His book was published in 1754, and, though he had made some progress in preparing his materials before he left Northampton, was certainly written, and nearly completed, within the time ascertained by the two letters referred to, and must be admitted to convey a very striking idea, both of his mental resources and of his literary ardour."

In 1757, on the death of Mr Aaron Burr, Mr Edwards was chosen president of New Jersey College. He had only been here, however, a very short time, when he was carried off on the 22d of March 1758, in the fifty-fifth year of his age, by the small-pox. This disease was at that time raging in the neighbourhood. Mr Edwards, who had never had it, proposed to be inoculated, which his physicians approved of. He had the disease favourably, but a secondary fever set in, and by reason of a number of pustules in his throat, the obstruction became such that he could not swallow the necessary medicines, and the fatal result was what we have stated. The character of Mr Edwards is that of a very primitive, self-mortified, simple, and amiable man, and affords a strong proof of the power of genuine Christian piety upon the heart, in spite of the most gloomy and repulsive tenets. He was solely occupied with his professional duties and his theological studies, insomuch that, as is mentioned with inimitable simplicity by the author of his life, "he was less acquainted with most of his temporal affairs than many of his neighbours, and seldom knew when and by whom his forage for winter was gathered in, or how many milk-kine he had; whence his table was furnished," or by what means his wants were provided for. Mrs Edwards, however, a most valuable and sensible woman, fully supplied his defects in these particulars. We must quote another passage from this piece of biography, which is equal in simplicity, though by no means in any thing else, to some of the exquisite biographies of Isaac Walton. After being informed that he did not permit dancing, against which

---

[1] This primitive piece of biography, from which all our quotations are taken, is prefixed to a volume of sermons published after Mr Edwards' death. Its author is not mentioned. The edition from which we quote is printed at Edinburgh, by Alexander Jardine, 1799.

amusement, indeed, he wrote a sermon, we are told that "he allowed not his children to be from home after nine o'clock at night, when they went abroad to see their friends and companions; neither were they allowed to sit up much after that time, in his own house, when any came to make them a visit. If any gentleman desired acquainttance with his daughters, after handsomely introducing himself, by properly consulting the parents, he was allowed all proper opportunity for it, and a room and fire, if needed; but must not intrude on the proper hours of rest and sleep, nor the religion and order of the family."

Mr Edwards comes nearer Bishop Butler as a philosophical divine than any other theologian with whom we are acquainted. His style, like Butler's, is very much that of a man thinking aloud. In both these authors the train of thinking in their own minds is more clearly exhibited to us than perhaps by any other writer, whilst they show us with great truth and distinctness what their notions are, and how they came by them, with very little concern about the form of expression in which they are brought out. Butler, however, had a larger mind than Edwards, and was by no means so much of a mere dialectician. If, therefore, he be less acute than the American, he is more comprehensive, and gives fairer play to every opposing argument. We do not mean here to enter into any of Edwards' speculations. Both on the subject of original sin, and on the freedom of the will, he seems to us to unite a great deal too closely the views which originated, as we have seen, in no small degree, amidst his early reveries, with the infallible discoveries of divine revelation. Our notion is, that in all discussions on such subjects which have hitherto appeared, the speculatists have forgotten how little a part either of the history or the nature of man we are in fact acquainted with; and how ready we ever are, in laying the foundations of our theories, to place a tortoise beneath the elephant. The whole difficulty, for instance, on the freedom of the will, turns upon a puzzle in the idea of cause and effect. Perhaps this idea is far from being precise in our minds (Mr Edwards uses it very loosely in his speculations); yet we do not scruple, in our reasonings upon it, to draw the most positive inferences from the assumptions with which we set out. We suspect, indeed, that the true and accurate notion of causation always involves the idea of volition; and, on that supposition, to ask for the cause of volition itself is absurd. It may be very true that we cannot will to do any thing without previous thought or motive; neither can we think without previous existence. But is our existence the cause of our thinking? Just as much as our thinking is the cause of our willing. We are far, however, from wishing to add our own crude conceptions to those which have been piled up on this subject from the beginning of time to the present hour, without, we believe, doing the slightest service to the cause of moral and religious truth, or accomplishing any thing, in short, beyond affording an exercise for ingenuity, and too often a handle for uncharitable rancour and presumptuous absurdity. Mr Edwards, with all his great powers, has accordingly, we apprehend, done but little good to the world, we mean as a philosopher; for he did much good in his own day, whilst he was living the life of a zealous and faithful Christian minister. But it is "thus we play the fools with the time; and the spirits of the wise sit in the clouds and mock us." Exalted above all the folly of human wisdom, the spirit of this truly good and pious man is now, it may be, disposed to regard with some such sentiment many of his own most severe and laborious speculations, which were carried on in the serious belief, that if "the knots of Calvinism were trimmed off, or its doctrines, in the whole length and breadth of them, were not rigidly maintained, a man could nowhere set his foot down with consistency and safety, short of Deism, or even Atheism itself, or rather universal Scepticism."

Edwards' works consist of several volumes of sermons, printed at various times, and often reprinted in this country as well as in America. Besides these, he wrote, 1. *A Treatise concerning Religious Affections*, 1746, 8vo; 2. *An Account of the Life of the Reverend David Brainerd*, 1749, 8vo; 3. *An Inquiry into the Qualifications for full Communion in the Visible Church*, 1749, intended as a vindication of his principles in the matter which occasioned his dismission from Northampton; 4. *A careful and strict Inquiry into the Modern Notion of that Freedom of Will which is supposed to be essential to Moral Agency*, 1754; 5. *The Great Christian Doctrine of Original Sin defended, containing a Reply to the Objections of Dr John Taylor*, 1758; 6. *A History of Redemption*; 7. *Miscellaneous Observations on Important Theological Subjects*, London, 1793; 8. *Remarks on Important Theological Controversies*, ibid. 1796. Some of these were posthumous, as were a few other tracts of less importance written by him. (L. L. L.)

EEKEREN, a town of the Netherlands, in the province of Antwerp, about four miles from that city. It has some distilleries and tanneries, and 4740 inhabitants.

EECHAAK, a town of Hindustan, in the province of Bahar, 103 miles south-south-east from Patna. Long. 85. 46. E. Lat. 24. 10. N.

EEL. See Ichthyology.

EETCOORE, a town of Hindustan, in the province of Bahar, and district of Ramgur, 92 miles south from Patna. Long. 85. 17. E. Lat. 24. 18. N.

EFBE, an island in the Eastern Seas, about five or six miles in length, near the south coast of Mysol, with which it forms a harbour. Captain Forrest found two villages on the island, where vessels may procure supplies. Long. 127. E. Lat. 2. 12. S.

EFFEMINATE, womanish, unmanly, voluptuous.

Effeminate (*effeminati*), according to the vulgate, are mentioned in several places of Scripture. The word is there used to signify such as were consecrated to some profane god, and prostituted themselves in honour of him. The Hebrew word *hadesh*, translated *effeminatus*, properly signifies *consecrated;* and hence it was applied to those of either sex, who publicly prostituted themselves in honour of Baal and Astarte. Moses expressly forbids these irregularities among the Israelites; but the history of the Jews shows that they were notwithstanding frequently practised.

EFFENDI, in the Turkish language, signifies *master*, and accordingly is a title very extensively applied, as to the mufti and emirs, to the priests of mosques, to men of learning, and of the law. The grand chancellor of the empire is called *reis effendi.*

EFFERVESCENCE, an intestine motion excited among the parts of two bodies of different natures, when they reciprocally dissolve each other. Effervescences are commonly attended with bubbles, vapours, small jets of the liquid, and a hissing noise; which phenomena again are occasioned by the air disengaging itself. Sometimes also they are accompanied with a great degree of heat, from the decomposition of some substances and the formation of new compounds.

Formerly the word *fermentation* was also applied to effervescences; but now that word is confined to the motion naturally excited in animal and vegetable matters, and from which new combinations among their principles take place.

EFFIGY, the portrait, figure, or exact representation of a person.

Effigy, is also used for the print or impression of a coin, representing the prince's head who struck it.

Effigy, to execute or degrade in, denotes the execution or degradation of a condemned contumacious criminal, who cannot be personally seized.

EFFLORESCENCE, in *Chemistry*, denotes the formation of a kind of mealy powder on the surface of certain bodies. Efflorescence is occasioned either by decomposition or by drying. The efflorescence which happens to cobalt and martial pyrites is of the former; and that observed on the crystals of soda, Glauber's salt, and the like, of the latter kind. An efflorescence is sometimes also a species of crystallization, such as the beautiful vegetations which shoot up from different saline substances. See Crystallization.

EFFLORESCENTIA, in *Botany* (from *effloresco*, to bloom), the precise time of the year and month in which every plant shows its first flowers. Some plants flower twice a year, as is common between the tropics; others oftener, as the monthly rose. The former are called by botanists *biferæ*, the latter *multiferæ*.

EFFLUVIUM, in *Physiology*, a term much used by philosophers and physicians to express the minute particles which exhale from most, if not all, terrestrial bodies, in form of sensible vapours.

EFFRONTES, in *Ecclesiastical History*, a sect of heretics, in 1534, who scraped the forehead with a knife till it bled, and then poured oil into the wound. This ceremony served them instead of baptism. They are likewise said to have denied the divinity of the Holy Spirit.

EFFUSION, the pouring out of any liquid. In the ancient heathen sacrifices there were divers effusions of wine and other liquors, called *libations*.

Effusion, or Fusion, in *Astronomy*, denotes that part of the sign Aquarius represented on celestial globes and planispheres by the water issuing out of the urn of the water-bearer.

EGENOTISO, an island in the Eastern Seas, about twenty miles in circumference, and fifty miles from the north-east coast of Sumatra. Long. 104. 45. E. Lat. 0. 27. S.

EGER, a circle of the Austrian kingdom of Bohemia, extending over 110 square miles, and containing 22,500 inhabitants. The chief place is the city of the same name. It contains 776 houses, and 8111 inhabitants, who are employed in various manufactures. It is celebrated as the place where Wallenstein was put to death, and also for its mineral water, which is extensively dispensed in Germany. Long. 12. 18. E. Lat. 50. 5. N.

EGERIA, a nymph who assisted Numa in framing a code of laws for the people of Rome. The king and the nymph used to meet at night in a wood at the gates of Rome, then called Lucus Camœnarum, which is now, according to popular opinion, *La Caffarella*. When Numa died, Egeria was so violently affected with grief, that she frequently interrupted by her weeping the sacrifice of Diana, till the goddess in pity changed her into a fountain of the same name. (Ovid. *Met.* xv. 547; Liv. i. 19; Juv. v. 10.)

EGG, in *Physiology*, a body formed in certain females, in which is contained an embryo or fœtus of the same species, under a cortical surface or shell. The exterior part of an egg is a shell, which in a hen, for instance, is a white, thin, and friable cortex, including all the other parts. The shell becomes more brittle by being exposed to a dry heat. It is lined everywhere with a very thin but pretty tough membrane, which dividing at or very near the obtuse end of the egg, forms a small bag, where only air is contained. In new-laid eggs this follicle appears very little, but becomes larger when the egg is kept. Within this are contained the albumen or white, and the vitellus or yolk; each of which has its different virtues. The albumen is a cold, viscous, white liquor in the egg, different in consistence in its different parts. It is observed, that there are two distinct albumens, each of which is inclosed in its proper membrane. Of these, one is very thin and liquid, the other is more dense and viscous, and of a somewhat whiter colour, but, in old and stale eggs, after some days incubation, inclining to a yellow. As this second albumen covers the yolk on all sides, so it is itself surrounded by the other external liquid. The albumen of a fecundated egg is as sweet and free from corruption during the whole time of incubation as it is in new laid eggs; and so is also the vitellus. As the eggs of hens consist of two liquors separated one from another, and distinguished by two branches of umbilical veins, one of which goes to the vitellus, and the other to the albumen; so it is very probable that they are of different natures, and consequently appointed for different purposes. When the vitellus grows warm with incubation, it becomes more humid, resembling melting wax or fat; and hence it occupies more space. For as the fœtus increases, the albumen insensibly wastes away and condenses; the vitellus, on the contrary, seems to lose little or nothing of its bulk when the fœtus is perfected, and only appears more liquid and humid when the abdomen of the fœtus begins to be formed. The chick in the egg is first nourished by the albumen, and, when this is consumed, by the vitellus, as with milk. If we compare the *chalazæ* to the extremities of an axis passing through the vitellus, which is of a spherical form, this sphere will be composed of two unequal portions, its axis not passing through its centre; consequently, since it is heavier than the white, its smaller portion must always be uppermost in all positions of the egg. The yellowish white round spot, called *cicatricula*, is placed on the middle of the smaller portion of the yolk; and therefore, from what has been said above, must always appear on the superior part of the vitellus. Not long before the exclusion of the chick, the whole yolk is taken into its abdomen; and the shell, at the obtuse end of the egg, frequently appears cracked some time before the exclusion of the chick. The chick is sometimes observed to perforate the shell with its beak. After exclusion, the yolk is gradually wasted, being conveyed into the small guts by a small duct.

Eggs differ very much, according to the birds which lay them, as to their colour, form, size, age, and the different ways of dressing them: those most used in food are hens' eggs. As to the preservation of eggs, it is observed that the egg is always quite full when it is first laid by the hen; but from that time it gradually becomes less and less so, till its decay; and however compact and close its shell may appear, it is nevertheless perforated with a multitude of small holes, though too minute for the discernment of our eyes, the effect of which is a daily decrease of matter within the egg, from the time of its being laid. This perspiration is much quicker in hot weather than in cold. To preserve the egg fresh, there needs no more than to preserve it full, and stop its transpiration; the method of doing which is, by stopping up those pores with matter which is not soluble in watery fluids; and on this principle it is that all kinds of varnish, prepared with spirit of wine, will preserve eggs fresh for a long time, if it be carefully rubbed all over the shell. Tallow, or mutton fat, is also good for this purpose.

Artificial Method of Hatching Eggs. See Hatching.

EGGENFELDEN, a bailiwick of the circle of the Lower Danube, in the kingdom of Bavaria, extending over 220 square miles. It contains five market-towns, 133 villages, and 867 hamlets, with 22,566 inhabitants. The capital is the town of the same name. It is situated on the river Roth, and contains 226 houses, with 1340 inhabitants.

EGHAM, a village of the hundred of Godley and Chertsey, in the county of Surrey, 18 miles from London. It is situated on the banks of the Thames, which is the boundary towards Middlesex, and over which is a bridge connecting it with Staines. The great western road passing through it gives some animation. The country around it is pleasant. The population amounted in 1801 to 2190, in 1811 to 2823, in 1821 to 3616, and in 1831 to 4203.

EGINHARD, or EGINHART, a celebrated historian of the ninth century, was a native of one of the eastern provinces of France. His family is not known, and those who have pretended that he was of noble descent have given no other proof of their assertion than the reception which he met with at the court of Charlemagne. He was instructed in letters by Alcuin, who foresaw the success of his pupil, and recommended him to the favour of the emperor. Being afterwards admitted to receive lessons along with the young princes, he justified the opinions which had been formed of his merits by the progress which he made in his studies; and Charlemagne, wishing to attach to his person a young man of so much promise, appointed the latter his secretary. Eginhard is said to have formed a strong attachment for Emma or Imma, one of the daughters of Charlemagne, whom, with the consent of the emperor, he is stated to have espoused; but, however this may be, it is certain that he married a lady of rank belonging to the court of Charlemagne. The expressions in the ancient manuscripts, though somewhat vague, leave no doubt as to this circumstance. After the death of Charlemagne, Eginhard passed into the service of Louis le Debonnair, who confided to him the education of his son Lothaire. But use and experience having inspired him with a disgust for the court, he obtained permission to quit it; and accordingly having resigned his employments, he withdrew to the monastery of Fontenelle, whilst his wife Emma, and his son Vussin, also embraced the monastic life. Having governed this monastery during seven years, he, in 823, resigned the administration to his friend Ansegise, and then retired first to the abbey of St Pierre, and afterwards to that of St Bavon de Gaud. He afterwards left his retreat, however, and returned to the court, where he is stated by some to have taken part in the troubles of which Louis le Debonnair became the victim. But this is contradicted by his letters, which prove that he neglected no means to prevent the execution of the plot entered into against this unfortunate prince by his own children. Eginhard is supposed to have died about the year 839. He left several works, of which the following are the most important: 1. *Vita et Gesta Caroli Magni*, Cologne, 1521, in 4to, rare; 2. *Annales Regum Francorum Pipini, Caroli Magni, Ludovici Pii, ab anno Christi* 741 *ad annum* 829, contained in the collection of Pierre Pithou, Paris, 1588, and Francfort, 1613; 3. *Eginhardi Epistolæ*, contained in the collection of Duchêne, tom. ii. in the *Eginhardus Vindicatus* of John Weinekens, and also in the collection of Dom Bouquet; 4. *De Translatione SS. Martyrum Marcellini et Petri*; 5. *Breviarium Chronologicum ab orbe condito ad Ann. Chr.* 809, which is merely an abridgment of the Chronicle of Bede.

EGMONT ISLAND, or NEW GUERNSEY, the principal island in the group called Queen Charlotte's Islands, in the South Pacific Ocean. It is about 54 miles in length, and from 20 to 32 in breadth. The country in general is mountainous, covered with woods, and intersected with numerous valleys and small rivers. The inhabitants are brave, vigorous, and active, but treacherous and dishonest. Long. 166. E. Lat. 11. S.

EGMONT ISLAND, a small woody island in the South Pacific Ocean, six miles in length by about four in breadth. Long. 138. 30. W. Lat. 19. 20. N.

EGNATIA, or GNATIA, a city of Peucetia, a province of Apulia, situated on the coast, the inhabitants of which are ridiculed by Horace for exciting the wonder of the ignorant multitude by burning incense on an altar without the process of ignition. Pliny, with the utmost gravity, makes the prodigy still more surprising, by stating that this sacred stone possessed the power of setting fire to any species of wood by mere juxtaposition (ii. 107). Attempts of this kind to impose on the credulity of a superstitious people were by no means uncommon amongst the ancients; and this trick, with some slight variations, was practised by the priests in very different parts of the world. Aristotle mentions a stone in Thrace from which, on being moistened with water, flames issued forth; and, according to Pliny, the same thing occurred in the country of the primitive Sabines. In Lydia, Pausanias was witness to a miracle of a somewhat similar nature. There was a small chapel set apart for this particular purpose; on entering he found the altar covered with ashes of a peculiar colour, and one of the magi having made his appearance, placed dry wood upon it, and his tiara on his head. He then repeated a few prayers, when a beautiful and brilliant flame issued from the altar without the application of fire. This city gave name to the Via Egnatia, which passed from Brundusium through Egnatia to Canusium. Its ruins are found at the *Torre d'Agnazzo*, where the inhabitants still pretend to show the temple alluded to by Horace.

EGREMONT, a market-town of the ward of Allerdale, in Cumberland, about five miles from the sea, and 290 from London. It formerly returned members to Parliament; and the family of Wyndham derive from a castle near it, now dilapidated, the title of earl. The market is held on Saturday. The population amounted in 1801 to 1515, in 1811 to 1741, and in 1831 to 1741.

EGYPT.

Egypt, a country not less remarkable for its physical character than its historical records, and forming as it were the connecting link between Africa and the civilized world, consists, first, of a long and narrow valley, which follows the course of the Nile from Assouan to Cairo; and secondly, of the extensive plain which is situated between the northern extremity of this valley and the Mediterranean Sea. Including the valley and the plain, it extends from the parallel of 24° N. where the river appears to force a passage for itself through the mountains of Nubia, to the vicinity of Damietta, in 31° 35′ N. where the principal stream discharges itself into the ocean. The natural boundaries of Egypt are so distinctly marked, that its nominal or territorial extent has seldom much exceeded the area which is included within its physical limits. Immediately above the cataracts of Syene, or Assouan, there is a small island, called Philæ by the Greeks, and Bilak by the Arabs,[1] which from the earliest times constituted the southern limit or extremity of Egypt. From Syene to Cairo, the river flows along a narrow valley, included between two mountain ridges, which an Arabian author calls "the wings of the Nile," one of them extending to the Red Sea, and the other terminating in the deserts of ancient Libya. The river occupies the middle of the valley as far as the strait called Djibbel-Silsili, which is about forty miles long; but at the mouth of this strait it runs along the right side of the valley, which is bounded by a steep line of rocks, cut as it were into peaks, whilst the ridge of hills on the left side is less precipitous, and generally presents an accessible slope, varying in acclivity. The mountains which confine the basin of the Nile in Upper Egypt are intersected by defiles, which on one side lead to the shores of the Red Sea, and on the other to the Oases.[2] Near Benisouef, the valley of the Nile, already much widened on the west, presents on that side an opening, through which are observed the fertile plains of Fayoum, forming a sort of table-land, separated from the surrounding mountains on the north and west by a wide valley, of which a portion, always laid under water, constitutes what the inhabitants call Birket-el-Kâroon. From the southern extremity of the Delta, near Cairo, the mountains recede eastward and westward; one called Djibbel-el-Nairon, stretching north-west towards the Mediterranean, the other named Djibbel-el-Attaka, running straight east to Suez, and both forming an angle of divergence of about 140°. At Battu-el-Bahara the river divides into two large branches, one of which flowing to Rosetta, and the other to Damietta, contain between them the triangular piece of insulated land called from its shape the Delta, Δ. The whole length of this tract, from Philæ in 24° 3′ 45″ N. to the northernmost point of the Delta, amounts to about four hundred and fifty geographical miles; the mean width of the valley between Syene and Cairo is about nine miles; and the whole area, or superficial extent, from the shores of the Delta to the first cataract, falls little short of eleven thousand square miles.[3]

The country of which we have described the boundaries and configuration is one which, to the scholar, the antiquary, and the philosopher, has long appeared the most interesting on the face of the earth. If not the very first, it was at least amongst the earliest, seats of civilization, which, from causes altogether unknown, struck its roots deep into the alluvial mud of the Nile. Long before the nations of the West had emerged from their primeval forests, Egypt had reached its zenith, and exhibited, completely formed, that extraordinary state of society in respect of laws, government, religion, and manners, which has occupied without exhausting the curiosity of succeeding times. The land of the Pharaohs was at once the cradle of science, the birth-place of letters, and the parent source of art as well as superstition; and, at a period long anterior to the dawn of civil history in other countries, it was covered with those monuments which the fury of five successive conquests, and the ravages of near forty centuries, have failed to annihilate. To Egypt Greece was indebted for the letters, science, art, philosophy, laws, government, and superstition, which she afterwards extended, altered, modified, or improved; and hence the polished nations of modern Europe, whose civilization is principally a derivative of that of ancient Greece, may trace the rudiments of their science, literature, and arts, to the ingenious people who were the primary instructors of the Greeks, and who, from a period far beyond the records of history, had settled on the banks of the Nile. But out of the materials which have reached our times, and which, in their transit through so many ages, have suffered almost every species of injury and mutilation, it must obviously be a task of prodigious difficulty to construct a chain of narrative, which shall connect the present with the past, without omitting some essential links; and it is plainly impossible, from piecing together mere fragments of ruins, to establish an unbroken concatenation between that which is and that which has once been. Like the bridge in the vision of Mirza, which in its nearer portion appeared tolerably entire, but in its more remote consisted only of broken arches, which gradually disappeared in the impenetrable mist that overhung the vast ocean of time in which it was lost, the history of Egypt, though it enables us to advance a certain way with a considerable degree of security, becomes at length only a collection of dislocated fragments, and is finally lost in that abyss of the elder time, of which there exists neither record nor monument. Still the materials on which we have to work are more ample and various than might be suspected by a superficial or perfunctory inquirer. We have, first, those monumental remains which have outlasted the ravages of time, war, revolution, conquest, and fanatical barbarism; we have, next, the direct accounts or incidental notices and statements of the Greek, Roman, and Arabian writers; we have, thirdly, the lights which modern science has diffused respecting the monuments which ancient science had constructed, and the institutions which ancient policy had founded; and we have, lastly, the marked advantage derived from the partial success which has crowned the efforts of modern ingenuity in attempting to decipher those inscriptions and writings which have formed the mystery of ages. From all these sources, and aided by the learned labours of those distinguished archæologists who have devoted themselves

---

[1] Both words, *Philæ* and *Bilak*, are corruptions of the Coptic word *Pi-lakh*, meaning extremity. Quatremère, *Mémoires Géographiques sur l'Egypte*, i. 388.

[2] Malte-Brun, *Universal Geography*, iv. 22, English Translation.

[3] Girard, *Mémoires sur l'Egypte*, iii. 4.

to illustrate the history, literature, and antiquities of ancient Egypt, we hope to derive sufficient materials to enable us to exhibit a clear and distinct digest of all that is at present known respecting the wonderful country, whose learning had become proverbial even in the days of Moses, and whose high civilization is attested by the colossal splendour of its monumental ruins. With this view we shall commence with its civil history.

SECTION I.

HISTORY OF ANCIENT EGYPT.

Origin and Etymology of the name.—High Antiquity of early Egyptian History.—Obscurity in which it is involved.—The only authority on which dependence can be placed.—Territorial Division of Egypt.—Whence and how peopled.—Ancient Inhabitants.—Copts.—Reign of the Priests.—Revolution.—Menes.—Age of this Monarch determined.—His Character and Actions.—Commencement of Legitimate History.—Fabulous extravagance of the Egyptian Chronology.—Dynasties from Menes to Mœris.—Invasion and Conquest of Egypt by the Shepherds.—Substance of Manetho's account.—Additional particulars of these Invaders.—Havoc committed by them.—Their ultimate expulsion and retreat into Syria.—Opinion of Bruce as to the origin of this people.—Other opinions.—Indian tradition respecting the Pali or Shepherds.—Palestine.—Expulsion of the Shepherds not to be confounded with the Exode of the Israelites.—Amenoph.—Thothmosis I.—Thothmosis II.—Mœris.—Thothmosis III.—Works executed by these Pharaohs, particularly Mœris.—Lake Mœris or Lake Fayoum.—Rhamses the Great, otherwise called Sesostris.—Era of this Conqueror.—His Education.—His Exploits.—His Indian Expedition.—Results.—Return of Sesostris.—Usurpation and treachery of his brother.—Expulsion of Armaïs, called also Danaus.—General State of Egypt at this period.—Monuments erected and Improvements executed.—Component parts of the Egyptian Empire.—Internal condition.—Division of the people into Castes.—Trade, Commerce, and Industry.—Successors of Sesostris.—Rhamses-Meiammon.—His Military Enterprises and Civil Labours.—State of Egypt under the succeeding Pharaohs.—Expeditions of Chechonk and Osorchon.—Ethiopian Invasion and Conquest of Egypt.—Sabacon.—Anysias.—Sethon.—Twelve contemporary Kings.—Psammeticus I.—His proceedings.—Attempt made by him to discover the Sources of the Nile.—Pharaoh-Necho or Nechus.—Circumnavigation of Africa.—War with Assyria.—Nechus defeated by Nebuchadnezzar, who became master of Egypt to the gates of Pelusium.—Psammeticus II. or Psammis.—Pharaoh-Hophra or Ouaphré, called also Apries.—His treachery towards the Jews.—Egyptians defeated by the Cyreneans.—Revolt.—Apries defeated by Amasis, and strangled by his own people.—Reign of Amasis.—Condition of Egypt.—Amasis succeeded by Psammenitus.—Persian Invasion under Cambyses.—Siege and capture of Pelusium.—Egyptians defeated in a general battle.—Capture of Memphis.—Barbarity of the Conquerors.—Fatal consequences of the invasion.—Depressed state of Egypt.—Insurrections.—Put down by the Persians.—Alexander the Great.—Greek Dynasty.—Ptolemy Lagus, called also Soter.—Events of his Reign.—His Character.—Ptolemy Philadelphus, surnamed Euergetes.—His Expeditions and Conquests.—Favour shown by him towards the Jews.—State of the Egyptian empire at this period.—Ptolemy Philopater.—Dissolute character of this Prince.—His Cruelty.—Conduct towards the Jews.—Minority.—Ptolemy Epiphanes.—Ptolemy Philometor.—Euergetes II. called also Physcon.—Disputed Succession.—Various fortune of the struggle.—Interference of the Romans in the Affairs of Egypt.—Death of Philometor.—Monstrous cruelty of Physcon.—His treatment of his wives; an Egyptian Henry VIII. in this respect.—Revolt.—Physcon restored.—His Death.—Ptolemy Lathyrus.—Cleopatra his mother.—Revolt quashed.—Capture and destruction of Thebes.—Alexander II.—His barbarous conduct.—Ptolemy Auletes.—Events of his Reign.—Policy of Rome respecting Egypt.—Pompey.—Julius Cæsar.—Mark Antony.—Conduct of Auletes.—His Death.—Cleopatra and her brother Ptolemy Dionysius.—Expulsion of the former.—Restored by Cæsar after Pharsalia.—Death of Cæsar.—The Triumvirate.—Defeat and Death of Antony.—Suicide of Cleopatra.—Egypt reduced into a province of the Roman Empire.—Hadrian.—Severus.—Claudius.—Aurelian.—Introduction of Christianity.—State of Egypt under Constantine.—Rise and Progress of Islamism.

The country latterly known by the name of Egypt was anciently denominated סצרים, *Mitzraim*, מצור, *Matzor*, and האריץכם, *haretz Cham*, the land of Cham. These names, especially the first, occur frequently in Scripture, and, according to the general opinion, the country was called *Mitzrim*, or *Mitzraim*, after the second son of Cham, though some have been inclined to think that the second son of Cham might have been called *Mitzrim*, after the country. The name of *Mitzrim*, pointed by the Masorites *Mitzraim* in the dual form, probably indicated the two divisions of Egypt into Upper and Lower. Bochart has clearly established that מצור, *Matzor*, signifies a fortress; and that Egypt was so called either from its being a region fortified by nature, or from the word *tzor*, which signifies *narrow*, and is sufficiently descriptive of the valley of Upper Egypt. The first of these etymologies, however, is to be preferred, because amongst the ancients Upper Egypt was considered as a natural fortification. With regard to *Mitzrim*, it is most probably a contracted mode of writing *Matzorim*, the plural of *Matzor*; and as it may be considered as perilous to give it a dual form on the authority of the Masorites, the word *Mitzrim*, with its plural termination, may therefore be held as denoting the Upper, the Middle, and Lower Egypt. Amongst the ancient inhabitants of the country, it was denominated *Chemi* or *Chame*, either from *Chmom*, signifying heat, or from *Chame* or *Kame*, signifying black, probably by reason of the burnt and black appearance of the soil. The etymology of the word *Egypt* has occupied the attention and puzzled the ingenuity of many learned writers. The most common opinion is, that Αἴγυπτος is composed of *αἶα* for *γαια*, *terra*, land, and Γυπτος, or rather Κοπτος, and consequently signifies the *land of Kopt*, or the *Koptic land*. But this etymology has been objected to; first, by reason of the alleged improbability that the whole country would be so named from an obscure town in the Thebais; and, secondly, because it was the river, and not the land on its banks, which was first called Ægyptus; objections which appear to be insuperable. The more probable opinion is that the word *Aiguptos* is a mere softening of *Gups-Pta*, or *Aigups-Ptas*, formed of *gups* or *aigups*, a vulture, and *Pta* or *Ptas*, dæmon; the vulture being one of the principal symbols of the *Ikh-Ptahor* or *Dæmon Ptah* of the ancient Egyptians. But be this as it may, there can be little doubt that, whatever be the true etymology of the word *Aiguptos* or *Ægyptus*, the name of Copts or Kobths is nothing else than a corruption of the Greek term; and that by the name of Kobthi were designated, first, the Egyptians in general, and afterwards the Christians of Egypt in particular. But the natives of Egypt were not known by the name of Copts until the time of Amru.[1]

The early history of Egypt claims a much higher antiquity than that of any other country, excepting perhaps China and Hindustan, and is consequently involved in darkness the more impenetrable. It is utterly impossible indeed to reconcile the accounts of different authors with each other, or with any common standard; and even the same authors are not always consistent with themselves. But some idea may be formed of the comparative value of the different catalogues of sovereigns, by observing which of them is confirmed by the testimony of the greatest number of respectable and unconnected writers, and by inquiring, at the same time, what internal evidence they afford of the truth or falsehood of their statements.

---

[1] Drummond's *Origines*, or Remarks on the Origin of several Empires, States, and Cities, vol. ii. chap. 2.

The only authorities on which dependence can be placed respecting the early history of Egypt, are Herodotus, Manetho, Eratosthenes, Diodorus Siculus, and Strabo, all of whom had been for longer or shorter periods in the country. Herodotus lived soon after the conquest of Egypt by the great Persian conqueror Cambyses, when the names of the later monarchs could scarcely have been forgotten. The earlier part of his history is certainly of a very apocryphal character; but as he does not continue the series of the kings further than Sesostris and Mœris, almost all his names are therefore sufficiently recent to be considered as within the province of legitimate history. Manetho lived under Ptolemy Philadelphus, to whom he dedicated his three books of the *History of Egypt;* and there is little doubt that the extracts preserved by Josephus, Eusebius, and Syncellus, although some of these may have passed from one compiler to another, are in general perfectly authentic. How much of the work was originally fabulous, and how much has been distorted by transposition and anachronism, it is impossible accurately to determine. But besides the original inadmissibility of so long a series of successive generations, the invention of which may possibly be imputed to the same national vanity which led the priests to boast to Herodotus of three hundred and thirty kings between Menes and Sesostris, there are several coincidences pointed out by Marsham, in the names and qualifications of princes mentioned at very remote periods, which tend strongly to encourage the opinion that the originals were respectively one and the same person. There are also other instances which render it not improbable that several of the persons enumerated may have been contemporary sovereigns of different subdivisions of the country: but, perhaps, this portion of Marsham's theory has been carried a little too far; and, amidst so much confusion, it is not to be wondered that all his learning and ingenuity should have failed to establish any satisfactory result. He holds the catalogue of Eratosthenes in high and just estimation, although he was not acquainted with the very strong argument in favour of its authenticity, derived from the agreement of many of the etymologies with the acknowledged meaning of the terms in the Egyptian language; an agreement, indeed, which renders it more than probable that Eratosthenes, who lived in the reign of Ptolemy Euergetes, did actually receive these names from the priests of Diospolis. This interesting catalogue has been successively copied by Apollodorus, Africanus, Eusebius, and Syncellus; but how many of the names contained in it were really those of actual sovereigns of Egypt, and how many had been negligently or ignorantly read and pronounced, it is by no means easy to ascertain. It may be observed, that scarcely any of them are to be found in the works of other chronologers or historians. Diodorus is, upon the whole, a very candid and judicious writer; and although some modern critics have entertained considerable prejudices against him, it will be afterwards found that he had a correct knowledge of the Egyptian institutions. The accuracy and good sense of Strabo are so well known, that we cannot but regret the paucity of historical facts respecting Egypt to be found in his writings. Besides the works of these authors, there is an anonymous chronicle copied by Africanus, and from him by Syncellus, which affords a series of kings somewhat shorter than that of Manetho, and also more regularly filled; but it seems to be principally a compilation from Manetho, with some reference to the contemporary events of the scriptural chronology.[1]

Such being the principal sources of early Egyptian history, we shall now proceed to the more immediate object of this section, namely, to exhibit an outline of the civil history of ancient Egypt. And here, in order to render our narrative intelligible, it is proper to state both the ancient and modern divisions of the country. These have been suggested by the course of the river, and the general configuration of the valley of the Nile, between the cataract of Assouan and the sea. Anciently this remarkable country was divided into three parts, namely, Upper Egypt, called the *Thebaid,* because Thebes was its capital; Middle Egypt, called the *Heptanomis,* or Seven Governments; and Lower Egypt, or the Delta, extending to the Mediterranean.[2] The Arabs and Ottomans have only changed the names of these divisions, which in fact are marked out by the hand of nature. First, Upper Egypt is called the *Saïd,* and includes the provinces of Thebes, Djirdjeh, and Siout; second, Middle Egypt, called the *Vostani,* consists of the provinces of Fayoum, Benisouef, and Minyeh; third, Lower Egypt, called *Bahari,* or the maritime country, includes the provinces of Bahyreh, Raschid or Rosetta, Gharbyeh, Menouf, Massoura, Sharkieh, and the Cairo district, consisting of the subdivisions of Kelioubeh and Atfihieh. The appellation of Upper Egypt is sometimes taken in a strictly physical acceptation, and made to include all the provinces above Cairo.

The first tribes who peopled Egypt, that is, the valley of the Nile between the cataract of Assouan and the sea, probably came from Abyssinia or Sennaar. The current of population appears to have descended along the course of the stream, and to have gradually overspread the valley fertilized by its waters; but it is impossible to fix the period of this first migration, which, however, must have been very remote. The ancient inhabitants of Egypt belonged to a race of men in most respects resembling the Kennous or Barabras, the actual inhabitants of Nubia. In the Copts of Egypt we find none of the characteristics of the ancient population of that country. The Copts are the product of a confused mixture of all the nations who have successively domineered over Egypt; and it would therefore be absurd to expect to find amongst them the characteristic features of the ancient race. The first settlers who arrived in Egypt were nomadic, and had not more fixed dwellings than the Bedouins of the present day; they were then destitute of science, of arts, and of definite forms of civilization. It was the work of ages of favourable circumstances which led the Egyptians, at first errant, to apply at length to agriculture, and to establish themselves in a fixed and permanent manner: then, and then only, arose the first towns, which in their beginnings were only small villages, but, by the successive development of civilization, became at length great and powerful cities. The most ancient towns of Egypt were Thebes (Luxor and Karnak) Esneh, Edfou, and the others of the Saïd above Dendera. Middle Egypt was then peopled; but Lower Egypt had neither inhabitants nor towns until a later period. It was only in consequence of prodigious works executed by the labour of man that Lower Egypt became habitable.[3]

[1] Young on Egyptian Literature and Antiquities, art. *Historiography of Egypt.*

[2] The figure of Egypt may be compared to the head and horn of an unicorn, the delta being the head, and the long narrow valley of the Nile the horn inserted, as it were, therein.

[3] "Notice Sommaire sur l'Histoire d'Egypte, redigée à Alexandrie pour le Vice-roi, et remise à S. A. au mois de Novembre 1829," being appendix No. 1 to the "Lettres écrites d'Egypte et de Nubie en 1828 et 1829, par Champollion le Jeune." Paris, 1833.

The Egyptians in the early stage of their progress were ruled by priests. The latter administered the government in every district of Egypt under a high priest, who again pretended to issue his orders in the name of God. This form of government, which is called a theocracy, resembled that by which the Arabians were governed under the first caliphs, though, in several respects, its construction was much less perfect. From its peculiar character, a government of this kind easily became unjust and oppressive, and, for a very long period, it retarded the advance of civilization. It had divided the nation into three distinct parts or castes; first the priests, then the military, and, thirdly, the people. The people alone laboured, and the fruit of all their toils was devoured by the priests, who kept the military in their pay, and employed them in keeping in check the rest of the population. But a period arrived when the military became weary of yielding a blind obedience to the priests. A revolution broke out, and the change which proved fortunate for Egypt was brought about by a military chief, named Menei or Menes, who became the head of the nation, established the royal government, and transmitted the power to his descendants in the direct line. From this period the country was ruled by kings, and the government became milder and more enlightened; for the royal power found a sort of counterpoise in the influence which the priesthood necessarily possessed, now that it was confined to its proper province of inculcating the laws of morality, and teaching the principles of the arts. Thebes still remained the capital of the kingdom; but king Menes, and his son and successor Athothes, laid the foundations of Memphis, which they rendered a strong city, and constituted their second capital. It was built at a short distance from the Nile; and its ruins have been found in the villages of Menf, Mokhnan, and particularly Mit-Rhahinch.

As the reign of Menes forms the extreme limit of legitimate curiosity in this interesting field of inquiry; and as all correct notions of Egyptian chronology must in a great measure rest on the determination of the period at which that monarch assumed or exercised the supreme power; various attempts have been made to fix this important epoch, from the data furnished either by monuments or by lists of dynasties and kings as given by the ancient authors. It will be sufficient for our present purpose, however, merely to state the results at which different inquirers have arrived. Menes, then, commenced his reign,

	B. C.	
According to Dr Hales, *New Analysis of Ancient Chronology*, vol. iv. p. 418	2412	
According to Old Chronicle, *New Analysis*, vol. iv. p. 407	2231	
According to Eratosthenes, Prichard's *Egyptian Antiquities*	2220	
According to Eusebius, *New Analysis*, vol. iv. p. 417	2258	or 2262
According to Julius Africanus, *ibid*	2218	
According to Dr Prichard, *Egyptian Antiquities*, p. 91	2214	

The mean of these different calculations is 2256, which, therefore, may be taken as perhaps the closest approximation to the truth. Amongst the principal authorities on which the reign of Menes has been determined as above, may be mentioned the statement of Josephus,[1] that Menes lived many years before Abraham, and that he governed Egypt more than 1300 years before Solomon. But Abraham was born 2153 years, and the son of David ascended the throne of Israel 1030 years before Christ; and these facts, combined with the account which is given in the old chronicle of the dynasty of kings which proceeded from Mitzraim, seem to warrant the conclusions of modern chronologers. It is evident, therefore, that Champollion has committed an egregious error in stating that, according to the ancient histories of Egypt, the epoch of the revolution which placed Menes on the throne was about six thousand years before the publication of Islamism. This is very nearly the double of the truth as ascertained by the very authorities to which he refers.

The actions of this monarch have been conveyed to us through the obscure and uncertain channel of tradition. On his accession he found the kingdom, like all priest-governed countries, in a most deplorable condition. Excepting the Thebais, the whole of it was a morass; and, though ruled by priests, the people were destitute of every kind of religion, as well as sunk in utter ignorance. According to Herodotus, Menes applied himself to remedy these evils. He diverted the course of the Nile, which before his time had washed the base of the sandy ridge near the borders of the Libyan desert, and thus protected from the inundations of the river the ground on which Memphis was afterwards erected. To accomplish this object, he erected a mound about twelve miles south from the future capital of Egypt; turned the course of the stream, a large branch of which had previously made its way through the valley of Fayoum, towards the Delta; and conducted it to the sea at an equal distance from the elevated ground by which on either side the country is bounded. Menes also acquired glory in war; but his best renown consists in having improved his country, and instructed his subjects in the arts of life. His death is said to have been occasioned by a hippopotamus.

We may here give an example of the fabulous extravagance of Egyptian chronology, as founded on the statements of the priests. Menes or Menas was the first mortal who sat upon the throne of Egypt, the country having before his time been governed by eight gods in succession. But Herodotus mentions, that the priests recited to him, from books, three hundred and thirty sovereigns, successors of Menes, of whom eighteen were Æthiopian princes, and one a queen called Nitocris. Now, allowing thirty-three years for a generation, the joint reigns of three hundred and thirty kings would amount to about eleven thousand years; a period which, according to the forged records of these priests, must have intervened between the reign of Menes and that of Sesostris. The statement of Diodorus Siculus, however, is by no means so violently opposed to truth and probability. He agrees with Herodotus in representing Menes as the first king of Egypt who reigned after the gods; but he says that after Menes fifty-two kings reigned during a period of fourteen hundred years, or about twenty-seven years at an average for each reign. This statement, though it falls short of the ordinary calculation, has at least a reasonable amount of probability in its favour, and indeed seems to be a pretty close approximation to the truth. Of the three hundred and thirty monarchs mentioned by Herodotus, on the authority of the sacred records, none except Mœris was distinguished by any acts of magnificence or renown; and hence he prudently abstains from loading his pages with the appellations and titles of this catalogue of royal lumber. It may, however, serve to assist the recollection of the reader, on this obscure and intricate subject, if we exhibit an abridged list of the kings who occupy the space between the accession of the first mortal sovereign of Egypt and the death of Mœris.

Death of Mœris	340	1308

During the long interval between the reign of Menes and the death of Mœris, the most remarkable event which occurred, and one, too, which forms the first distinct piece of history we meet with respecting Egypt, was the invasion of the Pastors or Shepherds, which, according to the chronology here adopted, took place more than two thousand years before the birth of Christ. This irruption, as related by Manetho, happened in the reign of Timaus king of Egypt, when God being displeased with the Egyptians, exposed them to a great revolution; for a multitude of men, of obscure origin, pouring from the East into Egypt, made war on the inhabitants, who, being apparently unwarlike, submitted almost without resistance. The Shepherds, however, behaved with the greatest cruelty; they burned the cities, threw down the temples of the gods, put to death the inhabitants, and carried the women and children into captivity. This people came from Arabia, and were called Hycsos, or King-Shepherds. They held Egypt in subjection for more than two centuries and a half, at the end of which period they were compelled by a king of Upper Egypt, named Amosis, or Thothmosis, to abandon the country. This prince's father had, it seems, gained great advantages over them, and shut them up in a place named Abaris or Avaris, that is, the Pass (afterwards called Pelusium), where they had collected all their cattle and plunder. Here they were closely besieged by Thothmosis with an army of 480,000 men; but at last the king, finding himself unable to reduce them by force, proposed a sort of capitulation, which was readily accepted: the Shepherds in consequence withdrew from Egypt with their families, to the number of 240,000 souls. Accordingly, they crossed the desert, and entered Syria; but fearing the Assyrians, who were then very powerful, and held Asia in subjection, they entered the land of Judæa, and built there a city capable of containing so great a multitude, which they called Jerusalem.

Such is the substance of Manetho's statement, as preserved by Josephus in his tract against Appion; and, with the exception of the concluding part, where he seems to identify the savage invaders of Egypt with the peaceful family of Jacob, its accuracy can scarcely be called in question. It appears, indeed, that these barbarians having established themselves in Egypt, tyrannized over it for several centuries; that the progress of civilization was arrested, and the inhabitants ruined, by exactions and rapine; that the barbarians having elected a chief, the latter took the name of Pharaoh; and that it was under the fourth of these foreign chiefs that Joseph the son of Jacob became the prime minister of Egypt, and afterwards brought thither the family of his father, which thus became the source of the Jewish nation. But in process of time different parts of Upper Egypt freed themselves from the yoke of the strangers; and at the head of this resistance appeared the princes descendants of the Egyptian line of kings whom the barbarians had dethroned. Of these the most distinguished was Amosis, who, having collected sufficient forces, drove them from Memphis, which they had made their capital; attacked them in Lower Egypt, where they were firmly established; and ultimately, by means of the capitulation of Avaris or Avara, delivered Egypt from their tyranny.

Various opinions have been entertained as to the origin of the detested race which overthrew Thebes and tyrannized over all Egypt. According to Bruce, the Shepherds who invaded Egypt were no other than the inhabitants of Barabra, and carriers to the Cushites, who lived farther to the south. The latter had built many stately temples in Thebes and other cities of Egypt; yet, according to him, they had no other dwelling-places than holes or caves in the rocks. Being a commercial people, they remained at home collecting and preparing their articles, which were dispersed by the Barabers or Shepherds already mentioned. These, from the nature of their employment, lived in moveable habitations, as the Tartars do at this day. By the Hebrews, he tells us, they were called Phut, but Shepherds by every other people; and from the name Baraber the word Barabra is derived. By their employment, which consisted in dispersing the Arabian and African goods all over the continent, they had become a great and powerful people; and, from their opposite dispositions and manners, were frequently enemies of the Egyptians. To Salatis Bruce ascribes the destruction of Thebes in Upper Egypt, so much celebrated by Homer for its grandeur and magnificence. In fact, he reckons three invasions of this people; the first being that of Salatis already mentioned, who overthrew the primary dynasty of Egyptian kings from Menes, and destroyed Thebes; the second that of Sabacon or So, a word which, according to him, was not the name of a single prince, but of a people, and signifies *shepherd;* and the third, when, after the building of Memphis, 240,000 of these people were besieged as above mentioned. But this hypothesis is in the highest degree inconsistent; for how is it possible that the third invasion, antecedent to the building of Jerusalem, could be posterior to the second, if the latter happened only in the days of Hezekiah?

---

[1] This is the 17th of Manetho.

There is less doubt as to the destruction of these barbarians. When forced to evacuate Egypt in virtue of the capitulation entered into with Amosis, they appear to have thrown themselves upon Syria, where several of their tribes fixed themselves, and became the ancestors of the Philistines, who occupied the eastern shores of the Mediterranean, and occasionally extended their power as far as the banks of the Euphrates.[1] It is not a little remarkable that a tradition of the conquest of the Shepherds is still preserved among the tribes of Central India. In one of the sacred books of the Hindus, a record is preserved of two migrations from the East in remote times; one of the Yadavas or Sacred Race, and the other of the Pali or Shepherds, who were a powerful tribe, and governed the whole country from the Indus to the mouth of the Ganges. Having passed the shores of the Persian Gulf, they took possession of Arabia, then crossed or turned the Red Sea, and occupied the lands on its western shore. But to a legend so wholly unsupported as this is, no weight or value can be attached. Many circumstances, however, conspire to render it probable that this people, whose memory was held in the greatest abhorrence in Egypt, by reason of their tyranny, were a Tartar or nomadic horde, and that, when expelled from that country, they settled on the shores of Syria, in the country which from them was called Palesthan or Palestine. The exode of the Israelites must not therefore be confounded with the expulsion of the Shepherds.

Amenoph, the son of Amosis, and the first of that name, having assisted in the expulsion of the Shepherds, with whom he had concluded the capitulation above mentioned, united all Egypt under his dominion, and raised the throne of the Pharaohs, that is to say, of the kings of the Egyptian race. He was the chief or head of the eighteenth dynasty. His entire reign, and that of his three successors, Thothmosis I., Thothmosis II., and Mœris-Thothmosis III. were devoted to the object of re-establishing a regular government, and raising up the nation, which had been crushed by so many years of servitude under a foreign yoke. The barbarians had destroyed everything; all therefore had to be reconstructed. These great kings spared no pains to raise up Egypt from its state of debasement; order was re-established throughout the whole kingdom; the canals, which had been neglected or destroyed, were repaired or re-formed; whilst agriculture and the arts, encouraged and protected, soon brought back abundance, and at once increased and perpetuated the resources of the government. In a little time the towns were rebuilt; edifices consecrated to religion appeared on all sides; and several of the monuments which are admired on the banks of the Nile belong to this interesting epoch of the restoration of Egypt by the wisdom of its kings. Of this number are the monuments of Semneh and Amada in Nubia, and several of those of Karnak and Medinet-Abou, which are the works of Thothmosis I. or of Thothmosis III. who is also called Mœris. This king, under whom the two obelisks of Alexandria were erected, is the Pharaoh who achieved the greatest undertakings; it is to him that Egypt owes the existence of the great lake of Fayoum. By immense works which he caused to be executed, and by means of canals and sluices, this lake became a reservoir which served to maintain, in the lower country, a perpetual equilibrium between the inundations of the Nile; to supply water when these were insufficient, or to withdraw it when they were excessive. Formerly it bore the name of Lake Mœris; at present it is called Birket-el-Karoun. These kings, and several of their successors, appear to have preserved in all its plenitude the royal power which they had recovered from the Shepherd chiefs; but they used it only for the advantage of the country, in correcting and reconstituting society, corrupted by slavery, and in restoring Egypt to the first political rank amongst surrounding nations.

At this period several nations of Asia had already attained a certain degree of civilization, and their power was believed to endanger the tranquillity of Egypt. Mœris and his successors often took arms, and carried the war into Asia or Africa, either to establish the dominion of Egypt, or to ravage and enfeeble those states, and thus to ensure the tranquillity of the Egyptian nation. Amongst these conquerors may be reckoned Amenoph II., the son of Mœris, who rendered tributary Syria and the ancient kingdom of Babylon; Thothmosis IV. who invaded Abyssinia and Sennaar; and, lastly, Amenoph III. who completed the conquest of Abyssinia, and undertook great expeditions into Asia. There still exist monuments of this king. It was he who caused to be built the palace of Sohleb in Upper Nubia, the magnificent palace of Luxor, and all that part south of the grand palace of Karnak at Thebes. The two colossal statues at Kourna are understood to represent this illustrious prince. His son Horus chastised a revolt of the Abyssinians, and continued the works of his father; but two of his children who succeeded him, having neither the firmness nor the courage of their ancestors, lost in a few years the influence which Egypt had exercised over neighbouring countries. King Menephtha I., however, restored the glory of the country, and carried his victorious arms into Syria, Babylonia, and even the north of Persia.[2]

We come now to the era of his son Rhamses the Great, known also in history by the name of Sesostris.[3] He was the first mighty warrior whose conquests are recorded with any degree of distinctness. Much diversity of opinion prevails as to the date of his reign. Some chronologers, among whom is Sir Isaac Newton, are of opinion that he is the Sesak or Shishak who took and plundered Jerusalem in the reign of Rehoboam the son of Solomon. Others, however, place him still earlier; and Mr Whitson contends that he was the Pharaoh who refused to part with the Israelites, and was at last drowned in the Red Sea. Larcher, who builds his calculation on Herodotus, asserts that Sesostris mounted the throne of Egypt 1356 years before Christ; Hales places his accession to the crown at the commencement of the thirteenth century before Christ; and Sir William Drummond, who contests the assertion of Larcher, fixes the commencement of his reign at a period still more recent, namely, about the beginning of the eleventh century anterior to our era. Mr Bryant, again, endeavours to prove that no such person ever existed; but that in his history, as well as in that of many ancient heroes, we have an abridgment of that of the Cushites or Babylonians, who spread themselves over great part of the then known world, and everywhere brought the people in subjection to them. His reign is the most extraordinary portion of the Egyptian history. The father of Sesostris was told in a dream, by the god Ptha, that his son, who was then newly born, should be lord of the whole earth. Upon the credit of this vision, he got together all the males in the land of Egypt who were born on the same day with Sesostris, appointed nurses and proper persons to take care of them, and had them treated like his own child; being persuaded that they who were the constant companions of his youth would prove the most faithful ministers and soldiers in his riper years. As they grew up they were inured to laborious exercises, and, in particular, were never permitted to taste food till they had performed a journey of upwards of twenty-two of our miles. When the old king imagined they were sufficiently educated and trained in martial exercises, he sent them, by way of trial of their qualities, against the Arabians. In this expedition Sesostris proved successful, and in the end subdued that people, who had never before been conquered. He was then sent to the westward, where he conquered the greater part of Africa, and was only stopped in his career by the Atlantic Ocean. Whilst he was absent on this expedition his father died; and then Sesostris resolved to fulfil the prediction of Ptha at his birth, by actually conquering the whole world. With this view he divided the kingdom into thirty-six provinces, and endeavoured to secure the affections of the people by gifts both of money and land. He forgave all those who had been guilty of offences, and discharged the debts of his soldiers. He then constituted his brother Armais or Harmais regent, but forbade him to use the diadem, and commanded him to offer no injury to the queen or her children, and to abstain from the royal concubines. His army consisted of 600,000 infantry, 24,000 cavalry, and 27,000 chariots. Besides these land forces, he had two fleets; one of them, according to Diodorus, of four hundred vessels. Of these fleets, one was designed to make conquests in the west, and the other in the east; and therefore the former was built on the Mediterranean, and the latter on the Red Sea. The first of these conquered Cyprus, the coast of Phœnicia, and several of the islands called Cyclades; and the second subdued all the coasts of the Red Sea; but its progress was stopped by shoals and other difficulties which the navigators of those days were unable to pass, so that he seems not to have made many conquests by sea.

---

[1] In the language of Asia the word *Pali* denotes shepherds, and *stan* or *sthan* means country; so that *Palis-tan* literally signifies shepherd-land, or the country of shepherds. But as *Palistan* is manifestly identical with *Palestine*, or the country of the Philistines, it is hence not improbable that the warlike nation which so frequently disputed the possession of the Syrian border with the descendants of Abraham were the progeny of the fierce herdsmen who for more than two centuries and a half held Lower, Middle, and even part of Upper Egypt subject to their despotic sway. (Russell's *Egypt*, p. 69, 2d ed.)

[2] Champollion, *Notice Sommaire sur l'Histoire d'Egypte*, 1829; *Lettres écrites d'Egypte*, appendix.

[3] This monarch has been designated by a great variety of names. Thus he has been called Sesostris, Sesoosis, Sesochis, Sesonchosis, Sethosis, Sethos, Ramesses, Rameses, Ramestes, Rhampstes, Rhamses, Vexores, and Ægyptus. But most of these appellations were probably titular. Thus, *Sesostris* may be ΣΕ-ΣΙΟΣ-Τ-ΡΗ, *Se-sios-t-re*, which signifies *filius domini, donum solis. Sesoosis* may, in like manner, be a corruption for ΣΕ-ΣΙΟΣ-ΣΙΟΣ, *Se-sios-sios, filius domini dominorum;* and *Ramesses*, derived from ΡΗ, *Ré, sol*, and ΜΕΣ, *mes, gignere*, may have signified *begotten by the sun.* But it is impossible to render ancient Egyptian according to the grammatical rules established in the Coptic language. (Drummond's *Origines*, vol. ii. p. 500.)

With the land forces Sesostris marched against the Ethiopians and Troglodytes, whom he overcame, obliging them to pay him a tribute of gold, ebony, and ivory. He then proceeded as far as the promontory of Dira, which lay near the Straits of Babelmandeb, where he set up a pillar with an inscription in sacred characters or hieroglyphics. He then marched on to the country where cinnamon grows, or at least to a country whence cinnamon at that time was brought, probably some place in India; and here he in like manner set up pillars, which were to be seen many ages afterwards. As to his further conquests, it is agreed by almost all authors of antiquity that he overran the greater part of the continent of Asia, and some part of that of Europe. Having crossed the Ganges, he erected pillars on its banks; and thence marching northward, he ascended the plateau of Central Asia, subdued the Assyrians and Medes, directed his course towards the Caspian and the Black Sea, and invaded the Scythians and Thracians. Authors are not agreed that he conquered the nations last mentioned. Some even affirm that he was overthrown with great slaughter on the banks of the Phasis, by Timaus, prince of the Scythians, and obliged to abandon a great part of his booty and military stores; but whether he was successful or the reverse in these parts, it is a common opinion that he settled a colony in Colchis. Herodotus, however, does not say whether the colony was designedly planted by Sesostris, or whether part of his army, having refused to accompany him further, settled in that region. From his own knowledge he asserts that the inhabitants of the country were undoubtedly of Egyptian descent. This was indeed evident from the personal resemblance they bore to the Egyptians, who were of swarthy complexions, with frizzled hair;[1] but more especially from the conformity of their customs, particularly that of circumcision. The utmost limit of this monarch's conquests, however, was in Thrace or Rumelia; for beyond this country his pillars were nowhere to be seen. These pillars he was accustomed to set up in every region which he conquered, with the following inscription, or one to the same purpose: "*Sesostris, King of Kings and Lord of Lords, subdued this country by the power of his arms.*" Besides these, he left also statues of himself, two of which, according to Herodotus, were to be seen in his time; the one on the road between Ephesus and Phocæa, and the other between Smyrna and Sardis. They were armed after the Ethiopian and Egyptian manner, with a javelin in one hand and a bow in the other; whilst across the breast a line was drawn from one shoulder to the other, with the following inscription: "*This region I obtained by these my shoulders.*" They were mistaken for images of Memnon.

The reasons assigned by this warlike prince for returning into Egypt from Thrace, and thus leaving the conquest of the world unfinished, were the want of provisions for his army, and the difficulty of the passes. Most probably, however, his return was hastened by the intelligence he received from the high priest of Egypt, concerning the rebellious proceedings of his brother, who, encouraged by his long absence, had assumed the diadem, violated the queen, and appropriated the royal concubines. On receiving this news, Sesostris hastened from Thrace, and, nine years after he had set out on his expedition, arrived at Pelusium in Egypt, attended by an innumerable multitude of captives taken from many different nations, and loaded with the spoils of Asia. His brother met him at this city, where, it is said, though with but little probability, Sesostris accepted from the traitorous regent an invitation to an entertainment. On this occasion he drank freely, as old soldiers are wont to do, whilst the queen and the rest of the royal family joined in the compotation; but during the entertainment Armais caused a quantity of dried reeds to be laid round the apartment where they were to sleep; and as soon as the party, filled with wine and wassail, had retired to rest, he set fire to the reeds. Sesostris, however, perceived the danger, and finding that his guards, overcharged with liquor, were incapable of assisting him, he rushed through the flames, and was followed by his wife and children. For this wonderful deliverance he made several donations to the gods, particularly to the god of fire; and he then took vengeance on his brother Armais, who is said to be the Danaus of the Greeks, and who, being now driven out of Egypt, withdrew into Greece, where, under his new name, he acquired great renown.

---

[1] These physical marks of the African race, although they may afford a proof that the founders of the Colchian colony were, if not Africans, at least of African descent, yet warrant not the conclusion that the ancient Egyptians belonged exclusively to this family of mankind. That Africans, particularly the inhabitants of the countries now called Nubia and Abyssinia, served in the army of Sesostris, seems to admit of little doubt; and it is by no means impossible that the founders of the Colchian colony were exclusively of this race, which having been subdued by Sesostris, and afterwards compelled to serve in his army, might naturally take the first opportunity that offered to detach themselves from a standard which to them was the emblem of subjection and humiliation. But it is a remarkable fact, that of the bodies found in the mummy cases, almost all those which have been unswathed and examined have strong red hair, and a cast of features somewhat resembling those of a New Zealander, and are as remote as possible from the general contour and expression of the negro countenance.

This illustrious conqueror, the history of whose achievements is so dashed and brewed with fable and romance, is generally supposed to have been one of the best of princes, as well as bravest of warriors. He employed all the riches taken from the conquered nations, and the tributes he received from them, in the execution of immense works of public utility. He founded new cities, endeavoured to elevate the ground of some, and surrounded others with strong embankments of earth, to protect them from the inundation of the river; he dug new canals, and to him is attributed the first idea of a canal for connecting the Nile with the Red Sea; and he covered Egypt with a great number of magnificent structures, many of which are still in existence. These are the monuments of Ibsambul, Derri, Guircheh-Hanan, and Wady-Essebouah, in Nubia; and in Egypt those of Kournah, of El Medineh near Kournah, a portion of the palace of Luxor, and the grand hall with columns in the palace of Karnak, which had been commenced by his father. This last monument is the most magnificent structure ever reared by the hand of man. But Sesostris did not confine himself to these more than Herculean labours. Not content with adorning Egypt with sumptuous edifices, and desirous to promote the real welfare of the people, he published a body of new laws, the most important of which was that which gave to all classes of his subjects the right of property in its fullest extent. By this he divested himself of that absolute and unlimited power which his ancestors had preserved after the expulsion of the Shepherds; and immortalized his name, which, in fact, was always venerated as long as there existed in the country a man of Egypt acquainted with ancient history. Hence it was under the reign of Rhamses the Great, or Sesostris, that Egypt arrived at the highest pitch of political power and internal splendour.

Amongst the countries which were either subject or tributary to him, this great monarch reckoned Egypt, the whole of Nubia, Abyssinia, Sennaar, several countries of the south of Africa; all the wandering tribes of the deserts east and west of the Nile; Syria; Arabia, in which the most ancient kings had establishments, near the valley of Pharaoh; and also in the places now called Djebbel-el-Mokatteb, El Magara, and Sabouth-el-Kadim, where there appear to have existed brass-founderies; the kingdoms of Babylon and Nineveh, now called Mossul; a great part of Anatolia, or Asia Minor; the Isle of Cyprus, and several islands of the Archipelago; and a considerable portion of the country now known by the name of Persia. At this period, when the star of the Pharaohs had reached its zenith, there existed regular and frequent communications between the Egyptian empire and that of India. The intercourse between these countries, indeed, appears to have been carried on with much activity; and the discoveries which are daily made in the tombs of Thebes, of stuffs of Indian fabric, of articles in wood the growth of India, and of hard-cut stones which certainly came from that country, leave no manner of doubt as to the commerce which ancient Egypt carried on with India, at a period when the European tribes and a great portion of the Asiatics were still in a state of barbarism. It is impossible indeed to explain the number and magnificence of the ancient monuments of Egypt, except on the supposition that the principal source of the immense wealth expended in producing them consisted in the ancient commercial prosperity of the country. Hence it is well ascertained that Memphis and Thebes were the first centre of that commerce, before Babylon, Tyre, Sidon, Alexandria, Tadmor (Palmyra), and Bagdhad, all cities in the vicinage, as it were, of Egypt, enjoyed that advantage and distinction.

With regard to the internal condition of Egypt at this period, it appears that the arts and the sciences, as well as what may be denominated police, were then carried to a high degree of advancement. The country was divided into thirty-six provinces or governments, administered by functionaries of different grades, according to a complete code of written laws. The population amounted in all to between five and seven millions. Of this a part specially devoted to the study of the sciences, and to promote the advancement of the arts, was charged, besides the ceremonies of worship, with the administration of justice, the assessment and collection of the imposts invariably fixed according to the nature and extent of each portion of property measured beforehand, and with all the branches of the civil administration. This was the instructed and learned part of the nation, and it was called the *Sacerdotal Caste*. The principal functions of this caste were exercised or directed by members of the royal family. Another portion of the Egyptian nation was specially entrusted with watching over the external defence, and guarding the internal tranquillity, of the country. It was in the numerous families endowed and supported at the expense of the state, and which formed the *Military Caste*, that all the conscriptions and levies of soldiers took effect. They regularly maintained the Egyptian army on the footing of a war establishment, at the total strength of about 180,000 men.[1] The third class of the population formed the *Agricultural Caste*. Its members devoted all their labour and attention to the cultivation of the soil, whether as proprietors or as farmers; and the products belonged to them *en propre*, subject only to the deduction of a portion destined for the support of the king, and also for that of the sacerdotal and military castes, which formed the principal, and indeed the most certain, revenues of the state. According to the statements of ancient historians, the annual revenue of the Pharaohs, including the tributes paid by foreign nations, may be estimated at not less than from L.27,000,000 to L.28,000,000 sterling. The artizans, the workmen of all kinds, and the merchants, composed the fourth class of the nation, or the *Industrious Caste*, which was subjected to a proportional impost, and thus contributed by its labours to defray the expense, as well as to augment the wealth, of the state. The productions of this caste raised Egypt to its highest pitch of prosperity. All kinds of industry were in fact practised by the ancient Egyptians; and their commerce with other nations more or less advanced, who formed the political world of that period, had experienced great development.

---

[1] The first but smallest of the divisions of this army was trained to fight on cars or chariots drawn by two horses. This constituted the *cavalry* of that period, for cavalry properly so called did not then exist in Egypt. The remainder consisted of corps of infantry of different arms, viz. the soldiers of the line armed with a cuirass, a buckler, a lance, and a sword; and the light troops, the archers, the slingers, and corps armed with hatchets or battle-axes. The troops were exercised in regular manœuvres, marched and performed movements in line by divisions and companies, and executed their evolutions to the sound of the drum and the trumpet. These circumstances indicate an advanced civilization. See the article ARMY.

Egypt carried on a regular and extensive commerce in the grain which remained after supplying its own consumption. It derived great profit from its herds, and also from its horses. It supplied the world with its linen fabrics and with its cotton tissues, equalling in perfection and in fineness any thing which India or Europe has yet produced. The metals, of which Egypt contained no mine, but which it derived from the tributary countries, or by advantageous exchanges with independent nations, came out of its workshops manufactured into various forms, and changed either into arms, instruments, utensils, or into articles of luxury and dress, which were eagerly sought after by all the neighbouring nations. It exported annually a considerable quantity of pottery of every kind, as well as innumerable products wrought in glass and in enamel; arts which the Egyptians had carried to the highest pitch of perfection. Lastly, it provided the neighbouring nations with *papyrus* or *paper*, formed from the interior pellicles of a plant which several centuries ago ceased to exist in Egypt.[1] The Egyptians had no monetary system at all similar to ours. For small commerce they had a money of convention; but in considerable transactions payments were made in rings of pure gold of a certain weight and diameter, or in rings of silver of a denomination and weight equally fixed. With them silver was a legal tender as well as gold. In regard to the state of the marine at this early period, we have not sufficient information to enable us to speak with confidence. It appears, however, that Egypt had a navy composed of large galleys, propelled both by oars and sails; and it may be presumed that the mercantile marine had also made considerable advances, although it is not improbable that commerce and navigation on an extended scale were carried on, in quality of brokers or agents, by a small tributary people of Egypt, whose principal cities were Sour, Saïd, Beirout, and Acre. In short, the internal prosperity of Egypt was founded on the great development of its agriculture and its industry. In the tombs of Thebes and of Sakkara are discovered at every step objects of improved and elaborate workmanship, showing that this people were acquainted with all the comforts of life, and all the enjoyments of luxury. No nation, ancient or modern, has in truth carried further than the old Egyptians the grandeur and richness of their edifices, or taste and *recherche* in furniture, utensils, costume, and decoration.

Such was Egypt at the period of its greatest known splendour. This prosperity dates from the epoch of the last kings of the eighteenth dynasty, to which belonged Rhamses the Great or Sesostris; a sovereign terrible to his enemies, but the benefactor of the nation, which he governed with prudence, and improved by his wise institutions. His successors enjoyed in peace the fruits of his labours, and preserved the greater part of his conquests, which the fourth of these in order, called *Rhamses-Meiammon*, a warlike and ambitious prince, still further extended, his entire reign being occupied with a series of successful enterprises against the most powerful nations of Asia. This king built the beautiful palace of Medinet-Abou at Thebes, on the walls of which may still be seen sculptured and painted all the campaigns of this Pharaoh in Asia, the battles which he fought on land and on sea, the siege and capture of several cities, and the ceremonies of his triumph on his return from his distant expeditions. This conqueror appears also to have improved the navy of Egypt, which had been neglected by his immediate predecessors.

Under the Pharaohs who reigned after Rhamses surnamed Meiammon, or Beloved of Ammon, Egypt enjoyed a long tranquillity. During this period of profound repose, although the warlike and conquering spirit with which the country had been animated during the preceding dynasties declined, Egypt must necessarily have improved its internal government, and advanced progressively in art and industry; but its external dominion became contracted from age to age, by reason of the increasing civilization of the countries, which thus scarcely owned its sway, and which, improved by their very connection with Egypt, could not be kept in subjection except by means of a military establishment out of all proportion to the resources and population of that country. A new political world had in fact been formed around Egypt. The tribes of Persia, incorporated into one nation, already menaced the great united kingdoms of Nineveh and Babylon; whilst, on the other hand, the latter, aiming at depriving Egypt of important branches of commerce, disputed with that country the possession of Syria, and employed the Arab nations and tribes to harass its frontiers. In this conflict, the Phœnicians, naturally the commercial agents of these powerful rivals, sided sometimes with the one party and sometimes with the other, according to the interest of the moment; but the struggle was long and obstinate, the commercial existence of one or other of these powerful empires being at stake.

The military expeditions of Pharaoh Chechonk I. and those of his son Osorchon I. who overran Western Asia, maintained during some time the supremacy of Egypt; and it might long have enjoyed the fruits of these victories, if an invasion of Æthiopians or Abyssinians had not turned its whole attention to the south. But all its efforts were unavailing. Sabacon, king of the Ethiopians, having seized upon Nubia, passed the last Cataract with an army augmented by all the barbarous races of Africa, and poured this savage horde like a torrent down the valley of the Nile. After an unavailing struggle, in which its native prince, Pharaoh Bok-hor, perished, Egypt yielded to the conqueror. Sabacon began his reign with an act of great cruelty, causing the conquered prince to be burnt alive; nevertheless, when he saw himself firmly established on the throne of Egypt, he is said to have become a new man, and in fact he is highly extolled for his mercy, clemency, and wisdom. Sabacon is probably the So mentioned in Scripture, who entered into a league with Hoshea king of Israel against Shalmaneser king of Assyria.

Of Sabacon's immediate successor little or nothing is known. After him reigned Sethon, who was both king and priest of Ptha. He gave himself up to religious contemplation; and not only neglected the military class, but deprived them of their lands. They were so much incensed at this, that they entered into an agreement not to bear arms under him; and in this state of affairs Sennacherib king of Assyria arrived before Pelusium with a mighty army. Sethon now applied to his soldiers, but in vain; they unanimously persisted in refusing to march under his banner. Being therefore destitute of all human aid, he had recourse to Ptha, who, according to the legend, promised, that if Sethon would but go out against the Assyrians, he should obtain a complete victory. Encouraged by this assurance, the king assembled a body of artificers, shopkeepers, and labourers, and with this undisciplined rabble marched towards Pelusium. He had no occasion, however, to fight; for the very night after his arrival at Pelusium, an innumerable multitude of field rats having entered the enemies' camp, gnawed to pieces the quivers, bowstrings, and shield straps; so that, next morning, when Sethon found the enemy disarmed, and on that account beginning to fly, he pursued them with terrible slaughter. In memory of this extraordinary event, a statue of Sethon was erected in the temple of Ptha, holding in one hand a rat, whilst the words, "Whosoever beholdeth me, let him be pious," appeared to be issuing from the mouth.

---

[1] The *papyrus*, called *berd* by the ancient Arabs, grew principally in marshy soils, and the cultivation of it proved a source of wealth to those who lived on the banks of Lakes Bourlos and Menzaleh or Tennis.

Soon after the death of Sethon, the form of government was totally changed, and the kingdom divided into twelve parts, over which as many of the chief nobility presided. But this division subsisted only for a short time; for Psammeticus I. one of the twelve, dethroned all the rest, fifteen years after the division was made. The history of Egypt now begins to be divested of fable; and from this time it may be accounted as certain as that of any other ancient nation. The vast conquests of Sesostris were now merely matters of tradition, and Psammeticus possessed only Egypt itself. Indeed none of the successors of Sesostris, not even that monarch himself, had made use of any means to keep in subjection the countries which he had once conquered. Perhaps his original design was rather to pillage than to conquer; and hence his vast empire speedily fell to pieces. Psammeticus, however, endeavoured to extend his dominions by making war on his neighbours; but by putting more confidence in foreign auxiliaries than in his native subjects of the military caste, the latter were so much offended that upwards of 100,000 fighting men emigrated in a body, passed the Cataracts, and took up their residence in Ethiopia, where they established an independent state. To repair this loss, Psammeticus earnestly applied himself to the advancement of commerce, and opened his ports to all strangers, whom he greatly caressed, contrary to the maxims of his predecessors, who had refused to admit them into the country. He also laid siege to the city of Azotus in Syria, which held out for twenty-nine years against the whole strength of his kingdom; a sufficient proof that, as a warrior, Psammeticus was by no means very formidable to his enemies. He is said to have been the first king of Egypt who drank wine. He also sent to explore the sources of the Nile, and attempted to discover the most ancient nation in the world by an experiment which has been often recorded. Having procured two newly-born children, he caused them to be brought up without hearing the sound of a human voice; imagining that these children would naturally speak the original language of mankind. When, therefore, at two years of age, they pronounced the Phrygian word for bread, or some sound resembling it, he concluded that the Phrygians were the most ancient people in the world. This Pharaoh was but an indifferent logician.

Nechus, the son and successor of Psammeticus, and the Pharaoh-Necho of Scripture, was a prince of an enterprising and warlike genius. In the beginning of his reign he attempted to cut through the isthmus of Suez, between the Red Sea and the Mediterranean; but owing to obstacles which nature had thrown in the way of such an undertaking, he was obliged to abandon the enterprise, after having lost 120,000 men in the attempt. After this he sent a fleet, manned with Phœnician mariners, on a voyage to explore the coast of Africa. Accordingly, having left the Red Sea, he sailed round the continent of Africa, doubling the Cape of Good Hope, and after three years returned to Egypt by the Mediterranean, having of course passed the Straits of Gibraltar. The most remarkable wars in which this king was engaged are recorded in the sacred writings. He marched against the king of Assyria; and being opposed by the king of Judæa, he defeated and killed his opponent at Megiddo; after which he set up King Jehoiakim, and imposed on him an annual tribute of a hundred talents of silver and one talent of gold. He then proceeded against the king of Assyria, and having weakened him so much that the empire was soon afterwards dissolved, he became master of Syria and Phœnicia. But the end of his reign was unfortunate; for Nebuchadnezzar, king of Babylon, having come against him with a mighty army, the Egyptian monarch boldly ventured a battle, but was overthrown with great slaughter, and Nebuchadnezzar became master of all the country as far as the gates of Pelusium. His son Psammeticus II., called also Psammis, endeavoured to recover the provinces which had been detached from Egypt, but without success.

But his successor Apries, the Pharaoh-Hophra of Scripture, in Egyptian *Ouaphré*, was in some respects more fortunate. He is represented as a martial prince, and in the beginning of his reign as very successful. He took by storm the rich city of Sidon; and having overcome the Cypriots and Phœnicians in a sea-fight, returned to Egypt laden with spoil. It was probably this success which induced Zedekiah, king of Judæa, to enter into an alliance with Ouaphré against Nebuchadnezzar, king of Babylon; an alliance the unfortunate result of which was foretold by the prophet Jeremiah; for when Nebuchadnezzar sat down with his army before Jerusalem, Apries marched from Egypt to relieve the city, but no sooner did he perceive the Babylonians approaching him, than he retreated as fast as he could, leaving the Jews exposed to the mercy of their enemies. By this cowardly or treacherous conduct, Apries justly brought upon himself the vengeance denounced by the prophet. The Cyreneans, a colony of Greeks, being strengthened by a body of their countrymen under their third king Battus, and encouraged by the Pythian oracle, began to expel their Libyan neighbours, and divide among themselves the possessions of those whom they had driven out. In these circumstances Andica, king of Libya, sent an embassy to Apries to implore his protection against the Cyreneans. Apries complied with this request, and sent a powerful army to his relief. But the Egyptians were defeated with great slaughter; and those who returned complained that the army had been sent out in order to be destroyed, and that the king might tyrannize without control over the remainder of his subjects. This notion having caught the attention of the multitude, an almost universal defection ensued. Apries sent Amasis, a friend in whom he thought he could confide, to endeavour to bring back the people to a sense of duty. But he was betrayed by Amasis, who, taking the opportunity of the ferment, caused himself to be proclaimed king. Both parties now prepared for war. The usurper had under his command the whole body of native Egyptians, and Apries such Ionians, Carians, and other mercenaries as he could engage in his service. The army of Apries amounted only to 30,000; but though greatly inferior in number to the troops of his rival, yet as he well knew that the Greeks were much superior in valour, he did not doubt of victory. The two armies met, and drew up in order of battle near Memphis, where a bloody engagement ensued, in which, though the army of Apries behaved with the greatest resolution, they were at last overpowered by numbers, and utterly defeated, the king himself being taken prisoner. Amasis now took possession of the throne without opposition, and confined Apries in one of his palaces, but treated him with great care and respect. The people, however, were implacable, and Amasis therefore found himself obliged to deliver the prisoner into their hands. Apries was accordingly given up to those " who sought his life," and who no sooner had him in their power than they strangled him, and laid his body in the sepulchre of his ancestors.

During the reign of Amasis, Egypt is said to have been perfectly happy, and to have contained twenty thousand populous cities. That good order might be preserved amongst such vast numbers of people, Amasis enacted a law by which every Egyptian was bound once a year to inform the governor of his province by what means he gained his livelihood; and if he failed in this, he was liable to be put to death. The same punishment he decreed to those who could not give a satisfactory account of themselves. This monarch greatly favoured the Greeks, and married a woman of Grecian extract. To many Greek cities, as well as particular persons, he made considerable presents. He likewise gave permission to the Greeks in general to come into Egypt, and either settle in the city of Naucratis, or carry on their trade upon the sea coasts; granting them also temples, and places where they might erect temples, to their own deities. He likewise received a visit from Solon the celebrated Athenian lawgiver, and reduced the island of Cyprus under his subjection.

This prosperity, however, ended with the death of Amasis, or rather before it. The Egyptian monarch having somehow incensed Cambyses, king of Persia, the latter vowed the destruction of Amasis. In the mean time Phanes of Halicarnassus, commander of the Grecian auxiliaries in the pay of Amasis, received some private disgust, and leaving Egypt, set out for Persia. He was a wise and able general, well acquainted with every thing which related to Egypt, and held in great estimation by the Greeks resident in that country. Amasis became immediately sensible of his loss, and therefore sent after him a trusty eunuch in a fast-sailing galley. Phanes was accordingly overtaken in Lycia, but not brought back; for having made his guard drunk, he continued his journey to Persia, and presented himself before Cambyses as the latter was meditating the destruction of the Egyptian monarchy.

But Amasis had not the misfortune to behold the calamities of his country.[1] He died about 525 years before Christ, after a reign of forty-two years, and left the kingdom to his son Psammenitus, just as Cambyses was approaching the frontiers of the kingdom.

The new prince was scarcely seated upon the throne when the Persian host appeared. Psammenitus drew together what forces he could, in order to prevent the invader from entering the kingdom. Cambyses, however, immediately laid siege to Pelusium, and made himself master of the place by a stratagem. Having placed in the front of his army a great number of cats, dogs, and other animals which were deemed sacred by the Egyptians, he then attacked the city, and took it without opposition; the garrison, which consisted entirely of Egyptians, not daring to throw a dart or shoot an arrow against their enemies, lest their weapons should kill some of the sacred animals. Cambyses had scarcely taken possession of the city, when Psammenitus advanced against him with a numerous army. But before the engagement, the Greeks who served under Psammenitus, in order to show their indignation against their treacherous countryman Phanes, brought his children into the camp, killed them in the presence of their father and the two armies, and then drank their blood. Enraged at so cruel an act, the Persians advanced to the combat, which proved long and bloody; but at the close of the day the Egyptians, overpowered by numbers, gave way. Cambyses prevailed, and the national independence of Egypt was for ever lost. Those who escaped from the field fled to Memphis, where they were soon after guilty of an outrage for which they afterwards paid dear. Cambyses sent a herald to summon them, in a small vessel from Mitylene; but no sooner did they observe this craft coming into the port, than they flocked down to the shore, destroyed the boat, tore in pieces the herald and all the crew, and afterwards carried their mangled limbs into the city in a kind of barbarous triumph. Not long afterwards, Memphis was taken by assault, and given up to pillage; whilst Psammenitus fell into the hands of an inveterate enemy, enraged beyond measure at the cruelties committed upon the children of Phanes, the Persian herald, and the Mitylenian sailors. The conquerors, being still a barbarous race, carried everywhere destruction and death. Thebes was sacked, its finest monuments were demolished or laid in ruins, and the iconoclastic fury of the conquerors raged even more fiercely against the temples than the palaces of the land, which was thus made desolate.

The rapid success of the Persians struck such terror into the Libyans, Cyreneans, Barcæans, and other dependents or allies of the Egyptian monarchy, that they immediately submitted. Nothing now remained but to dispose of the captive king, and revenge on him and his subjects the cruelties which they had committed. This the merciless victor executed in the severest manner. On the tenth day after Memphis had been taken, Psammenitus and the chief of the Egyptian nobility were ignominiously sent into one of the suburbs of that city; and the king being there seated, saw his daughter coming along in the habit of a slave with a pitcher to fetch water from the Nile, and followed by the daughters of the first families in Egypt, all in the same miserable garb, with pitchers in their hands, drowned in tears, and loudly bemoaning their miserable situation. When the fathers observed their daughters in this distress, they all burst into tears, except Psammenitus, who only cast his eyes on the ground and kept them fixed there. After the young women came the son of Psammenitus, with two thousand of the young nobility, all of them with bits in their mouths and halters round their necks, who were led to execution. This was done to expiate the murder of the Persian herald and the Mitylenian sailors; for Cambyses caused ten Egyptians of the first rank to be publicly executed for every one of those who had been assassinated. Psammenitus himself was afterwards restored to his liberty, and had he not showed a desire of revenge, might perhaps have been entrusted with the government of Egypt; but being discovered hatching schemes against the conquerors, he was seized, convicted, and condemned to drink bull's blood.

---

[1] " Son règne fut heureux et paisible," says Champollion; " le commerce reprit un grand essor, et les richesses affluaient en Egypte; non qu'elle fût forte par elle-même, non qu'elle eût reconquis par les armes son influence au dehors, mais parce que dans ce temps-là les rois de Babylone cessaient de menacer l'Egypte pour résister aux peuples de la Perse, réunis sous un seul chef, Cyrus, qui attaqua impétueusement l'Assyrie et en fit graduellement la conquête, terminée par la prise et l'asservissement de Babylone." (*Notice sur l'Histoire de l'Egypte.*)

The Egyptians, now reduced to the lowest degree of slavery, were placed at the mercy of satraps or governors appointed by the conquerors. Their country became a province of the Persian empire, and the body of Amasis, their late king, being taken out of the grave, and mangled in a shocking manner, was finally burnt. Never was conquest more complete, desolation more universal, or tyranny more fierce and unrelenting. It was the very frenzy of barbarous fanaticism let loose, like some evil spirit long kept in chains under darkness, to destroy the monuments of the proudest civilization which the world had ever yet seen, and which in some of its characteristics had far distanced all future rivalry.[1] In the moral chaos which ensued, the arts and sciences almost entirely disappeared from that very soil in which they had long flourished; and the learning of the Egyptians became merely a recollection or tradition of the past. But what was accounted by the superstitious portion of the people more grievous than all the rest, the sacred bull Apis was slain, and his priests were ignominiously scourged; treatment which inspired the whole nation with an unextinguishable hatred of the Persians. A similar spirit of vengeance dictated the attempt to seize the consecrated fane of Jupiter Ammon, situated in the great Oasis; an attempt which cost Cambyses half his army, and produced disaffection among the remainder. As long as the Persian empire subsisted, the Egyptians were never able to shake off the yoke. They revolted frequently, it is true, but in every instance they were ultimately overthrown with prodigious loss. The chiefs who headed these insurrections gained partial successes, and for a brief space even freed their country from servitude; but their generous efforts were soon exhausted against the constantly increasing power of the Persian empire, and the expected deliverance was not achieved.

But when Alexander (Iskander), at the head of an army of Greeks, overturned the dominion of the Persians in Asia, Egypt at length respired freely under this new and enlightened master; and if he had lived he would doubtless have raised it to something like its ancient renown. He founded the city of Alexandria, which he called after his own name, and destined to become the centre of the commerce of the world, for which, from its geographical position, it was eminently calculated; and he was meditating other plans equally enlarged and comprehensive, when all his projects were suddenly arrested by death.

Having thus arrived at the point where commences the history of the Greek rulers of Egypt, we shall, in order to connect that which precedes with what is to follow, exhibit a tabular view of the several Egyptian dynasties from the death of Mœris-Thothmosis III. to the accession of the first Ptolemy, the head of the Lagidæ. It is proper to observe here, however, that this arrangement of the dynasties, founded on the information contained in the writings of Herodotus and Diodorus, differs very materially from that of Manetho, which will be presented under a subsequent head; and that it has been adopted in this place solely with a view to the illustration of the narrative, to which it is more immediately applicable than the royal canon of Manetho.

Fifth Dynasty, 342 *Years.*

	Y.	B. C.

Ochus reduces Egypt, Fourth Persian administration,	18	
Alexander conquers Egypt	81	332

---

[1] In a poetical "Address to the Mummy in Belzoni's Exhibition," which appeared about the time when that enterprising but unfortunate traveller exposed his Egyptian tomb and other curiosities to the view of the London public, and which has deservedly been admired for its picturesque vigour combined with richness and felicity of historical allusion, the fury which marked the whole career of the Persian conquest is indicated in the most graphic manner. Addressing the mummy, the poet asks—

Didst thou not hear the pother o'er thy head
  When the great Persian conqueror, Cambyses,
Marched armies o'er thy tomb with thundering tread,
  O'erthrew Osiris, Orus, Apis, Isis,
And shook the Pyramids with fear and wonder,
When the gigantic Memnon fell asunder?

On the demise of Alexander the Great the Greek generals divided amongst them his conquests, when Egypt, together with Libya, and that part of Arabia which borders on Egypt, were assigned to Ptolemy Lagus, as governor, under Alexander's son by Roxana, who was but newly born. But nothing was further from the intention of this governor than to hold these provinces in trust for another. He did not, however, assume the title of king until he found his authority too firmly established to be overthrown; nor did this happen until nineteen years after the death of Alexander, when Antigonus and Demetrius had unsuccessfully attempted the conquest of Egypt. Ptolemy then declared himself king, and became the head of the Greek dynasty which governed Egypt for nearly three centuries. From the time of his first establishment on the throne, Ptolemy, who had assumed the cognomen of *Soter*, reigned twenty years, which, added to the former nineteen, make up the thirty-nine years during which it is computed by historians that he reigned alone. In the thirty-ninth year of his reign he associated one of his sons, named Philadelphus, as his partner in the empire, at the same time declaring him successor to the throne, in prejudice of his eldest son, named Ceraunus; a preference which he was induced to give by his extravagant affection for Berenice, mother of Philadelphus. When the succession had been thus settled, Ceraunus immediately quitted the court, and fled into Syria, where he was received with open arms by Seleucus Nicator, whom, in order to evince his gratitude, he afterwards murdered.

The most remarkable transaction of this reign was the embellishing of the city of Alexandria, which Ptolemy made the capital of his new kingdom; and the establishment of the celebrated Alexandrian Library, in which were deposited all the treasures of ancient learning. (See the article ALEXANDRIA.) About 284 years before Christ, died Ptolemy Soter, in the forty-first year of his reign, and eighty-fourth of his age. He was the best as well as the most accomplished prince of his race, and he left behind him an example of prudence, justice, and munificence which few of his successors chose to imitate. Learned himself, he was a great patron and encourager of learning in others; and whilst he proved himself one of the most eminent philosophers of his age, he also invited to his court, and placed in the schools which he had established in Alexandria, all those who were then most distinguished for scientific acquirements. To him learning and philosophy owe numerous and deep obligations; and for nothing are they more indebted than the practical direction which he gave to the pursuits of science, by withdrawing the speculations of the learned from the entities and quiddities of metaphysics, and the barren subtilties of scholastic systems of disputation, in order to engage them in the more profitable studies of history, geometry, medicine, and philosophy. In this indeed consisted the true glory of his reign. The employment to which he devoted his accomplished mind, and the encouragement which he afforded to true learning, reflect greater honour upon the memory of Ptolemy Soter, than all the magnificence of the Serapeion, all the brilliant utility of the Pharos, or the success which crowned his arms and issued in the extension of his empire. Besides the provinces originally assigned to him, he acquired those of Cœlo-Syria, Ethiopia, Pamphylia, Lycia, Caria, and some of the Cyclades.

His successor, Ptolemy Philadelphus, added nothing to the extent of the empire; nor did he perform any thing worthy of notice except further embellishing the city of Alexandria, and entering into an alliance with the Romans. In his time Magas the governor of Libya and Cyrene revolted, and held these provinces as an independent prince, notwithstanding the utmost efforts of Ptolemy to reduce him to obedience. At last an accommodation took place; and a marriage was proposed between Berenice, the only daughter of Magas, and Ptolemy's eldest son. But before this treaty could be carried into effect, Magas died; and Apamea, the princess's mother, afterwards did all in her power to prevent the match. This, however, she was unable to effect, though her intrigues produced a destructive war of four years' continuance with Antiochus Theus king of Syria, and the enacting of a cruel tragedy in the family of that prince. Philadelphus conveyed the waters of the Nile into the deserts of Libya, finished the Pharos near the harbour of Alexandria, and laboured to improve the navigable canal which connected the capital with both the Red Sea and the Mediterranean. But he dishonoured himself by resenting the advice given to his father by Demetrius the librarian, who recommended to Lagus to allow the succession to proceed in the natural course, and to settle the crown on his eldest to the exclusion of his second son.

About 246 years before Christ, Ptolemy Philadelphus died, and was succeeded by his eldest son Ptolemy, who had been married to Berenice, the daughter of Magas, as above stated. In the beginning of his reign he found himself engaged in a war with Antiochus Theus king of Syria. In this, however, he proved victorious, and brought with him two thousand five hundred statues and pictures, amongst which were many of the ancient Egyptian idols, which had been carried away by Cambyses into Persia. These were restored by Ptolemy to their ancient temples, and in memory of this pious act the Egyptians conferred on him the surname of *Euergetes*, or the *Beneficent*. In the expedition against Theus he greatly enlarged his dominions, made himself master of several countries situated beyond Mount Taurus, and carried his arms to the confines of Bactria. An account of these conquests was drawn up by Ptolemy himself, and inscribed on a monument, to the following effect:

"Ptolemy Euergetes, having received from his father the sovereignty of Egypt, Libya, Syria, Phœnice, Cyprus, Lycia, Caria, and the other Cyclades, assembled a mighty army of cavalry and infantry, with a great fleet and elephants out of Trogloditia and Ethiopia, some of which had been taken by his father, and the rest by himself, and brought thence and trained up for war. With this great force he sailed into Asia, and having conquered all the provinces which are situated on this side of the Euphrates, Cilicia, Pamphylia, Ionia, the Hellespont, and Thrace, he crossed the river with all the forces of the conquered countries, and the kings of those nations, and reduced Mesopotamia, Babylonia, Susiana, Persia, Media, and all the country as far as Bactria."

On his return from this expedition, he passed through Jerusalem, where he offered many sacrifices to the God of Israel, and ever afterwards expressed great favour for the Jewish nation. At this time the Jews were tributaries of the Egyptian monarchs, and paid them annually twenty talents of silver. This tribute, however, Onias, then high priest, had for a long time neglected to pay, and the arrears in consequence now amounted to a very large sum. Soon after his return, therefore, Ptolemy sent one of his courtiers named Athenion to demand the money, and instructed him to acquaint the Jews that he would make war upon them in case of refusal. A young man, however, named Joseph, nephew of Onias, not only found means to avert the king's anger, but even got himself appointed receiver-general, and by his faithful discharge of that important trust continued in high favour with Ptolemy as long as he lived.

Having at last concluded a peace with Seleucus, the successor of Antiochus Theus king of Syria, Ptolemy Euergetes attempted the enlargement of his dominions to the south; and in this he was so successful that he made himself master of all the coasts of the Red Sea, both on the Arabian and Ethiopian shores, as far as the entrance of the Strait of Dira or Babelmandeb. On his return he was met by ambassadors from the Achæans, who came to implore his assistance against the Ætolians and Lacedæmonians. This the king readily promised; but the envoys having in the mean while engaged Antigonus king of Macedonia to support them, Ptolemy was so much offended that he sent powerful succours to Cleomenes king of Sparta, hoping thereby to humble both the Achæans and their new ally Antigonus. In this, however, he was disappointed; for Cleomenes, after having gained very considerable advantages over the enemy, was at last defeated in the battle of Sellasia, and obliged to take refuge in Ptolemy's dominions. He was received by the Egyptian monarch with the greatest kindness, and a yearly pension of twenty-four talents was assigned him, with a promise of restoring him to the Spartan throne; but before this could be accomplished, the king of Egypt died, in the twenty-seventh year of his reign, and was succeeded by his son Ptolemy Philopater.

At this period the Egyptian empire had attained to a great height of power; and if the succeeding monarchs had been careful to preserve what was transmitted to them by Euergetes, it is probable that Egypt might have been capable of holding the balance against Rome, and, after the destruction of Carthage, might have prevented that haughty city from becoming mistress of the world. But after the death of Ptolemy Euergetes, the Egyptian empire being governed only by weak or vicious monarchs, rapidly declined; and henceforth it makes no conspicuous figure in history. Ptolemy Philopater commenced his reign with the murder of his brother; after which he gave himself up to all manner of licentiousness, and the kingdom fell into a state of anarchy. Cleomenes the Spartan king still resided at court; and being now unable to bear the dissolute manners which prevailed there, he pressed Philopater to give him the assistance which had been promised for restoring him to the throne of Sparta. This he insisted upon the more, because he had received advice that Antigonus king of Macedonia was dead, that the Achæans were engaged in a war with the Etolians, and that the Lacedæmonians had joined the latter against the Achæans and Macedonians. Ptolemy, when afraid of his brother Magas, had indeed promised to assist the king of Sparta with a powerful fleet, hoping by this means to attach the latter to his own interest; but now when Magas no longer stood in the way, it was determined by the king, or rather his ministers, that Cleomenes should not be assisted, nor even allowed to quit the kingdom. Of the disorders which ensued in the government, Antiochus king of Syria, surnamed the Great, took advantage, and attempted to wrest from the hands of Ptolemy the provinces of Cœlo-Syria and of Palestine. But in this he was unsuccessful, and might easily have been driven altogether out of Syria, had not Ptolemy been too much occupied with his debaucheries to think of carrying on the war. The discontent occasioned by this negligence soon produced a civil war in his dominions; and the whole kingdom continued in the utmost confusion and disorder until his death, which happened in the seventeenth year of his reign and thirty-seventh of his age. A slave to his passions, addicted to cruelty, and incapable of governing, he at that early age sunk under a ruined constitution, amidst the universal scorn and contempt of mankind.

In this reign the Jews were inhumanly persecuted. The hatred of this people entertained by Philopater arose out of a remarkable occurrence. Whilst engaged in his Syrian expedition, the king of Egypt had attempted to enter the temple of Jerusalem; but he was prevented doing so by the Jews, a circumstance which filled him with the utmost rage against the whole nation. On his return to Alexandria, being resolved to make those who dwelt in that city feel the first effects of his vengeance, he published a decree, which he caused to be engraved on a pillar erected at the gate of his palace, excluding all those who refused to sacrifice to the gods worshipped by the king; by which means the Jews were debarred from suing for justice, or obtaining protection, when they happened to require it. By the favour of Alexander the Great, Ptolemy Soter, and Ptolemy Euergetes, the Jews at Alexandria had enjoyed the same privileges with the Macedonians. In that metropolis indeed the inhabitants were divided into three classes. In the first were the Macedonians, the original founders of the city, and the Jews; in the second were the mercenaries who had served under Alexander; and in the third the native Egyptians. By another decree, however, Ptolemy now ordained that the Jews should be degraded from the first rank, and enrolled among the native Egyptians; but that he might not seem to be an enemy to the whole nation, he declared that those who sacrificed to the gods of the Egyptians should enjoy their former privileges, and remain in the first class. Yet notwithstanding this tempting offer, only three hundred out of many thousand Jews who lived in Alexandria could be prevailed upon to abandon their religion in order to save themselves from slavery. Meanwhile, the apostates were excommunicated by their brethren; and this, being construed as done in opposition to the king's order, exasperated him so much that he resolved to extirpate the whole nation, beginning with the Jews who lived in Alexandria and other cities of Egypt, and proceeding thence even to Judea and Jerusalem itself. Accordingly he commanded the Jews who lived in any part of Egypt to be brought in chains to Alexandria, and there to be shut up in the Hippodrome; and having sent for the master of the elephants, he ordered that functionary to have five hundred of these animals in readiness against the next day, to be let loose upon the Jews. But when at length the elephants were let loose, instead of falling upon the Jews, they turned their rage against the spectators and soldiers, great numbers of whom were destroyed; and this elephantine retribution, together with some strange appearances which were at the same time observed in the air, so terrified the king, that he commanded the Jews to be immediately set at liberty, and restored them to their former privileges.

The death of Philopater was followed by a minority, his son and successor Ptolemy Epiphanes being only five years old at the period of his demise. This minority was chiefly remarkable for having afforded the Romans an opportunity of interfering in and powerfully influencing the affairs of Egypt. When, owing to the extreme youth of the Egyptian monarch, the kings of Syria and Macedonia had resolved to dismember and divide his dominions, the guardians of the young prince made application to Rome to interpose her authority in the cause of justice, and to prevent the aggrandisement of two grasping and unprincipled monarchs with the spoils of an unoffending country. It was always the policy of Rome to mask her ambitious views under the show of a regard to justice; and this application, which furnished the necessary pretence, whilst it held out hopes of future advantage, appeared too inviting to be refused. The request of the guardians was promptly granted, and Marcus Æmilius Lepidus set sail for Alexandria to assume the direction of affairs, whilst ambassadors were dispatched to Antiochus and Philip, to make known to them the line of policy which the republic had resolved to pursue. But the peace which Rome thus dictated terminated when Epiphanes took the sceptre into his own feeble hand. As he became corrupt, his subjects grew discontented; various conspiracies were formed against him; and although these were discovered and detected, he at length fell by the hands of an assassin, in the twenty-ninth year of his age, and the twenty-fourth of his reign.

Ptolemy Epiphanes was succeeded by Ptolemy Philometor, who was only six years old. In the beginning of this reign a war commenced with the king of Syria, who, in the preceding reign, had seized upon the provinces of Cœlo-Syria and Palestine. In the course of the war Philometor was either voluntarily delivered up to Antiochus, or taken prisoner; and the Alexandrians, despairing of his ever being able to recover his liberty, raised to the throne his younger brother, who took the name of Euergetes II., but was afterwards called Physcon, on account of the prominent abdominal rotundity which by his gluttony and sensual indulgence he had acquired. Physcon, however, was scarcely seated on the throne, when Antiochus Epiphanes, returning into Egypt, expelled him from that country, and restored the whole kingdom, except Pelusium, to Philometor. His design was to foment a war between the two brothers, that he might have an opportunity of seizing the kingdom for himself; and with this view he retained possession of the city of Pelusium, by which, as it formed the key of Egypt, he might at his pleasure enter the country. But Philometor, apprised of his design, invited Physcon to an accommodation, which was happily effected by their sister Cleopatra; and in virtue of the agreement then entered into, the brothers consented to reign jointly, and to oppose to the utmost of their power Antiochus, whom they considered as a common enemy. This family compact did not suit the views of the king of Syria, who invaded Egypt with a mighty army; but the Romans interfered, and prevented him from seizing on the country.

The two brothers were no sooner freed from the apprehensions of a foreign enemy than they began to quarrel with each other; and their differences soon reached such a height that the Roman senate interposed. But before the ambassadors employed to inquire into the merits of the cause could arrive in Egypt, Physcon had driven Philometor from the throne, and obliged him to quit the kingdom. On this the dethroned prince fled to Rome, where he was very kindly received by the senate, who immediately decreed his restoration. He was reconducted accordingly, and on the arrival of the ambassadors in Egypt, an accommodation between the two brothers was negociated. By this agreement Physcon was put in possession of Libya and Cyrene, and Philometor of all Egypt and the island of Cyprus; each of them being declared independent of the other in the dominion allotted to them. The treaty, as usual, was confirmed with oaths and sacrifices, and was broken almost as soon as made. Physcon was dissatisfied with his share of the dominions, and he therefore sent ambassadors to Rome to require that the island of Cyprus might be added to his other possessions. But this the ambassadors failed to obtain, and accordingly Physcon proceeded to Rome in person. His demand was evidently unjust, but the Romans, considering it as their interest to weaken the power of Egypt, without further ceremony adjudged to him the island in question.

Physcon set out from Rome along with two ambassadors; and having arrived in Greece on his way to Cyprus, proceeded to raise a number of mercenaries, with a design to sail immediately for that island and conquer it. But the Roman ambassadors having informed him that they were commanded to put him in possession of it by fair means, and not by force, he dismissed his army, and returned to Libya, whilst one of the ambassadors proceeded to Alexandria. Their design was to bring the two brothers to an interview on the frontiers of their dominions, and there to settle matters in an amicable manner. But the ambassador who went to Alexandria found Philometor averse to comply with the decree of the senate; and, in fact, he had recourse to so much evasion, that Physcon sent the other also to Alexandria, hoping that the joint persuasions of the two would induce Philometor to comply. But the king, after entertaining them at an immense charge for forty days, at last plainly refused to submit, and informed the ambassadors that he was resolved to adhere to the first treaty. Having received this answer, the Roman ambassadors departed, and were followed by others from the two brothers. The senate, however, not only confirmed the decree in favour of Physcon, but renounced their alliance with Philometor, and commanded his ambassador to leave the city in five days.

In the mean time the inhabitants of Cyrene having heard unfavourable accounts of Physcon's behaviour during the short time he reigned in Alexandria, conceived so strong an aversion to him, that it was resolved to exclude him from their country by force of arms. On receiving intelligence of this resolution, Physcon hastened with all his forces to Cyrene, where he overpowered his rebellious subjects, and established himself in the kingdom. But his vicious and tyrannical conduct soon estranged from him the minds of his subjects; and some of them, having entered into a conspiracy against him, fell upon him one night as he was returning to his palace, wounded him in several places, and left him for dead. This he laid to the charge of his brother Philometor, and, as soon as he had recovered, undertook another voyage to Rome, where he made his complaints to the senate, and showed them the scars of his wounds, accusing his brother of having employed the assassins from whom he had received them. Though Philometor was known to be a man of humane and mild disposition, and therefore unlikely to have been concerned in such an attempt, yet the senate, offended at his refusing to submit to their decree concerning the island of Cyprus, listened to this false accusation, and carried their prejudices so far as not only to refuse an audience to his ambassadors, but to order them to depart immediately from the city. At the same time they appointed five commissioners to conduct Physcon to Cyprus, and to put him in possession of that island; enjoining all their allies in those parts to supply him with forces for that purpose.

Physcon having by this means got together an army which appeared to be sufficient for the purpose, landed in Cyprus; but being there encountered by Philometor in person, he was entirely defeated, and obliged to shelter himself in a city called Lapitho, where he was closely besieged, and at last obliged to surrender. Every one now expected that Physcon would have been treated as he deserved; but instead of punishing, his brother restored him to the government of Libya and Cyrene, adding some other territories instead of the island of Cyprus, and promising him his daughter in marriage. Thus an end was put to the war between the two brothers; the Romans being ashamed any longer to oppose a prince who had given such a signal instance of justice and clemency.

On the death of Philometor, occasioned by wounds received in battle, Cleopatra the queen intended to secure the throne for her son. But some of the principal nobility having declared for Physcon, a civil war was about to ensue, when matters were compromised on condition that Physcon should marry Cleopatra, that he should reign jointly with her during his life, and that he should declare her son by Philometor heir to the crown. These terms were no sooner agreed to than Physcon married Cleopatra, and on the very day of the nuptials murdered her son in her arms. But this bloody deed was only a prelude to the cruelties which he afterwards practised on his subjects. He was no sooner seated on the throne as sole occupant than he put to death all those who had shown any concern for the murder of the young prince: he then wreaked his fury on the Jews, whom he treated more like slaves than subjects, on account of their having favoured the cause of Cleopatra; and even his own people were treated with little more ceremony. Numbers were every day put to death for the smallest faults, and often for no fault at all, but merely to gratify the inhuman temper of this tun-bellied despot. Towards the Alexandrians he acted with the greatest barbarity, indulging all the sanguinary caprices of the most wanton cruelty. In a short time, being wearied of his queen, who was his sister, he divorced her, and married her daughter, also called Cleopatra, whom he had previously ravished. In a word, his behaviour was so exceedingly wicked that it soon became quite intolerable to his subjects; and he was at length obliged to fly to the island of Cyprus with his new queen, and Memphitis, a son whom he had had by her mother.

After the flight of the king, the divorced queen was placed on the throne by the Alexandrians; but Physcon, fearing lest a son whom he had left behind should be appointed king, sent for him into Cyprus, and caused him to be murdered as soon as he landed. This barbarity so provoked the people against him, that they pulled down and dashed to pieces all the statues which had been erected to him at Alexandria. The indignant act of the people being attributed by the tyrant to the instigation of the queen, he resolved to revenge it, by putting to death the son whom he had by her. Accordingly, without the least remorse, he caused the young prince's throat to be cut; and having put his mangled limbs into a box, he sent them as a present to his mother Cleopatra. The messenger by whom this horrid present was conveyed was one of Physcon's guards; and the man had orders to wait until the arrival of the queen's birth-day, which was to be celebrated with extraordinary pomp, and in the midst of the general rejoicing to deliver the present. The horror and detestation occasioned by this unexampled piece of cruelty cannot be expressed. An army was soon raised, and the command of it given to Marsyas, whom the queen had appointed general, and enjoined to take all the necessary steps for the defence of the country. On the other hand, Physcon having hired a numerous body of mercenaries, sent them under the command of Hegelochus against the Egyptians. The two armies met on the frontiers of Egypt, and a bloody battle ensued; but at last the Egyptians were entirely defeated, and Marsyas was taken prisoner. Every one expected that the captive general would have been put to death with the greatest torments; but Physcon, perceiving that his cruelties only exasperated the people, resolved to try whether he might not regain their affections by lenity; and therefore, having pardoned Marsyas, he set him at liberty. In the mean time Cleopatra, distressed by this overthrow, demanded assistance from Demetrius king of Syria, who had married her eldest daughter by Philometor, at the same time promising him the crown of Egypt as his reward. Demetrius accepted the proposal without hesitation, marched with all his forces into Egypt, and laid siege to Pelusium. But as this prince was no less hated in Syria than Physcon was in Egypt, the people of Antioch, taking advantage of his absence, revolted against him, and were joined by most of the other cities in Syria. Demetrius was accordingly obliged to return; and Cleopatra, being now in no condition to oppose Physcon, fled to Ptolemais or St Jean d'Acre, where her daughter the queen of Syria at that time resided. Physcon was then restored to the throne of Egypt, which he enjoyed without further molestation till his death, which happened at Alexandria, in the twenty-ninth year of his reign, and sixty-seventh of his age.

Physcon was succeeded by Ptolemy Lathyrus, about a hundred and twenty-two years before Christ; but the latter had not reigned long when his mother, finding that he would not be entirely governed by her, stirred up the Alexandrians, who drove him from the throne, and placed on it his youngest brother Alexander. After this Lathyrus was obliged to content himself with the government of Cyprus, which he was still permitted to hold. But Ptolemy Alexander, finding that he was to have only the shadow of sovereignty, whilst his mother Cleopatra possessed all the power, stole away privately from Alexandria. The queen knowing well that the Alexandrians would never suffer her to reign alone, employed every artifice to bring back her son, who at last yielded to her entreaties; but soon afterwards understanding that she had hired assassins to dispatch him, he caused her to be murdered. The death of the queen was no sooner made known to the Alexandrians than, disdaining to be governed by a parricide, they drove out Alexander, and recalled Lathyrus.

The deposed prince for some time led a rambling life in the island of Cos; but having got together a few ships, he the next year attempted to return into Egypt, when, being met by Tyrrhus, admiral of Lathyrus, he was defeated, and obliged to fly to Myra in Lycia. From this place he steered his course towards Cyprus, hoping that the inhabitants would place him on the throne instead of his brother; but Chareas, another admiral of Lathyrus, having come up with him just as he was about to disembark, an engagement ensued, in which Alexander's fleet was dispersed, and he himself killed. During these disturbances, Appion king of Cyrenaica, the son of Ptolemy Physcon by a concubine, having maintained tranquillity in his dominions during a reign of twenty-one years, died, and by his will left his kingdom to the Romans; a bequest by which the Egyptian empire was still further reduced and circumscribed.

Lathyrus being now freed from all competitors, turned his arms against the city of Thebes, which had revolted against him, and declared itself independent. The king marched in person against the insurgents, and, having defeated them in a pitched battle, laid siege to the ancient metropolis of Egypt. The inhabitants, however, defended themselves with great resolution for three years; but at last they were obliged to submit, and the city was given up to be plundered by the soldiery, who everywhere left the most melancholy traces of their rapine and cruelty. This calamity completed the destruction of Thebes, which until that time, notwithstanding all it had suffered under the Persians, was a place of wealth and consequence; but by the barbarous and vindictive policy of Lathyrus, the venerable city was reduced to a heap of ruins. Its fate was indeed peculiarly hard. First Memphis, and then Alexandria, had arisen to obscure its ancient splendour, and to attract each into its own bosom the wealth and population of the country; nor is it to be wondered that the citizens of Thebes should have evinced a desire to recover some share of the distinction of which they had been gradually deprived, and to secure to the Egyptians a seat of government at a greater distance from the arms and intrigues of warlike neighbours. But they paid dear for the attempt to establish their independence, and the overthrow of Thebes, begun by the Persian, was completed by the Greek.

About eighty-one years before Christ, Ptolemy Lathyrus was succeeded by Alexander II., the son of the Ptolemy Alexander for whom Lathyrus had been expelled. This prince had met with many adventures. He was first sent by Cleopatra into the island of Cos, with a great sum of money, and all her jewels. But when Mithridates king of Pontus made himself master of that island, the inhabitants delivered up to him the young Egyptian prince, together with all the treasures. Mithridates gave him an education suitable to his birth; but Alexander, not thinking himself safe with a prince who had shed the blood of his own children, fled to the camp of Sylla the Roman dictator, who was then making war in Asia Minor. From that time he lived in the family of the Roman general, till the news of the death of Lathyrus reached Rome. Sylla then sent him to Egypt in order to take possession of the throne. But as the Alexandrians had before his arrival chosen Cleopatra as their sovereign, it was agreed, by way of compromise, that Ptolemy should marry this queen, and admit her as his partner in the throne. This was accordingly done; but it proved a fatal marriage to Cleopatra, for nineteen days thereafter the unhappy queen was murdered by her husband. Nor did the cruelty of the royal barbarian cease with the commission of this horrid crime. During the fifteen subsequent years he showed himself such a monster of wickedness, that a general insurrection at length broke out amongst his subjects, and he was obliged to fly to Pompey the Great, who was then carrying on the war against Mithridates king of Pontus. But Pompey having refused to concern himself in the matter, he retired to the city of Tyre, where he died some months afterwards.

While he remained at Tyre a sort of prisoner, Alexander sent ambassadors to Rome, in order, if possible, to move the senate in his favour. But having been seized with the illness of which he died, before the negotiation was concluded, he, by his last will, made over all his rights to the Roman people, declaring them heirs to his kingdom; not out of any affection to the republic, but with the view of raising disputes between the Romans and his rival Auletes, a son of Ptolemy Lathyrus, whom the Egyptians had placed on the throne. The will was brought to Rome, where it occasioned warm debates, some being for taking immediate possession of the kingdom, whilst others thought that no notice whatever should be taken of such a will, because Alexander had not the right to dispose of his dominions in prejudice of his successor, and to exclude from the crown those who were of the royal family of Egypt. Cicero, in particular, represented that such a notorious imposition would debase the majesty of the Roman people, and involve them in endless wars and disputes; that the fruitful fields of Egypt would be a strong temptation to the avarice of the people, who would insist on their being divided; and that by this means the sanguinary quarrels about the agrarian laws would be revived. These reasons had some weight with the senate; but what chiefly prevented them at this time from seizing on Egypt was, that they had lately taken possession of the kingdom of Bithynia in virtue of the will of Nicomedes, and of Cyrene and Libya in consequence of that made by Appion. They perceived that if they should, on a similar pretence, take possession of the kingdom of Egypt, this might expose their design of setting up a kind of universal monarchy, and cause a formidable combination to be formed against them.

Auletes, who now assumed and disgraced the title of Ptolemy, surpassed all the princes who went before him in the effeminacy of his manners. The surname of Auletes was given him because he valued himself on his skill in performing upon the flute, and was not ashamed even to contend for the prize in the public games. He took great pleasure in imitating the manners of the Bacchanals; he danced in a female dress, in the same measures which were used during the festivals of Bacchus; and he acquired a second surname descriptive of this particular accomplishment. As his title to the crown was disputable, the first care of Auletes was to get himself acknowledged by the Romans, and declared their ally; and this was obtained by applying to Julius Cæsar, who was then consul, and immensely in debt. Cæsar, glad of such an opportunity of raising money, made the Egyptian king pay dear for his alliance. Six thousand talents, a sum equal to about L.1,162,500 sterling, were paid partly to Cæsar himself, and partly to Pompey, whose interest was necessary for obtaining the consent of the people. Though the revenues of Egypt amounted to twice this sum, yet it was raised with great difficulty, and occasioned general discontent; and whilst the people were almost ready to take up arms, a decree passed at Rome for seizing the island of Cyprus. When the Alexandrians heard of the intentions of the republic, they pressed Auletes to demand that island as an ancient appendage of Egypt; and, in case of a refusal, to declare war against that haughty and imperious people, who, they now saw, though too late, aimed at nothing less than the sovereignty of the world. But the king having refused to comply with this request, his subjects, already provoked beyond measure at the taxes with which they were loaded, flew to arms, and surrounded the palace. The king, however, had the good fortune to escape their fury, and having immediately quitted Alexandria, set sail for Rome.

But on his arrival in the metropolis of the world he found that Cæsar, in whom he placed his greatest confidence, was then in Gaul. He was, however, received with great kindness by Pompey, who assigned him an apartment in his own house, and omitted nothing in his power to serve him. But notwithstanding the protection of so powerful a man, Auletes was forced to go from house to house soliciting the votes of the senators; and after he had spent immense treasures in procuring, or rather in purchasing, a strong party in the city, he was at last permitted to lay his complaints before the senate. It would have cost him less, and reflected more honour on his character, had he followed the advice given him by Cato, who, having met the fugitive prince at Cyprus, advised him to return to Egypt, and endeavour by more equitable conduct to regain the affections of his people, instead of repairing to Rome, where all the riches of Egypt would not be sufficient to satisfy the rapacity of the leading men. At the same time there arrived an embassy from the Alexandrians, consisting of a hundred citizens, who had been deputed to make the senate acquainted with the reason of their revolt.

When Auletes first set out for Rome, the Alexandrians, not knowing what had become of him, placed on the throne his daughter Berenice, and sent an embassy into Syria, to Antiochus Asiaticus, inviting him to come into Egypt to marry the queen, and to reign in partnership with her. Before the arrival of the ambassadors, however, Antiochus had died, upon which the same proposal was made to his brother Seleucus, who readily accepted it. This Seleucus is described by Strabo as monstrously deformed in body, and still more so in mind. The Egyptians nicknamed him Kybiosactes, or the Scullion; a sobriquet which seems to have fitted him entirely. Scarcely was he seated on the throne, when he gave a signal instance of his sordid and avaricious temper. Ptolemy Lagus had caused the body of Alexander the Great to be deposited in a sarcophagus of massive gold. This the royal Scullion seized upon; and thereby so provoked his wife Berenice that she caused him to be murdered. She then married Archelaus, high priest of Comana, in Pontus, who pretended to be the son of Mithridates the Great, but was, in fact, only the son of a general in the service of that illustrious monarch.

On hearing of these transactions, Auletes was not a little alarmed, especially when the ambassadors arrived, which he feared would overturn all the schemes in favour of which he had laboured and expended so much. The embassy was headed by Dion, a celebrated Academic philosopher, who had many powerful friends at Rome. But Ptolemy found means to get both him and most of his followers assassinated; and thus intimidated the rest to such a degree that they durst not execute their commission, nor, for some time, even demand justice for the murder of their colleagues. The report of so many murders, however, at last spread a general alarm. But Auletes, certain of the protection of Pompey, did not scruple to own himself the perpetrator of them; and though a prosecution was commenced against Ascitius, one of the assassins who had stabbed Dion, the chief of the embassy, and the crime was fully proved, yet the ruffian was acquitted by venal judges, who had all been bribed by Ptolemy. In a short time the senate decreed that the king of Egypt should be restored by force of arms; and all the great men in Rome were ambitious of this commission, which, they expected, would be attended with immense profit. Their contests on this occasion occupied a considerable time; and at last there was discovered a prophecy of the Sybil, which forbade the assisting an Egyptian monarch with an army. Ptolemy, therefore, wearied out with so long a delay, retired from Rome, where he had made himself generally odious, to the temple of Diana at Ephesus, there to await the decision of his fate. At this place he remained for a considerable time; but as he found that the senate came to no resolution, though he had solicited them by letters so to do, he at last, by Pompey's advice, applied to Gabinius, the proconsul of Syria, a man of most infamous character, and ready to undertake any thing for money. The application was successful; and, though it was contrary to an express law for any governor to go out of his province without positive orders from the senate and people of Rome, yet Gabinius ventured to transgress this law, upon condition of being well paid for his pains. As a recompense for his trouble, however, he demanded ten thousand talents; that is, about L.1,937,500 sterling. Glad to be restored on any terms, Ptolemy agreed to pay the sum demanded; but Gabinius refused to stir until he had received one half of it. This obliged the king to borrow it from a Roman knight called Caius Rabirius Posthumius, Pompey interposing his credit and authority for the payment of the principal sum and interest.

Gabinius now set out for Egypt, attended by the famous Mark Antony, who at this time served in the army under him. He was met by Archelaus, who since the departure of Auletes had reigned in Egypt jointly with Berenice, at the head of a numerous army; but the Egyptians were utterly defeated, and Archelaus taken prisoner in the first engagement. Gabinius might now have put an end to the war, but his avarice prompted him to dismiss Archelaus, on the latter paying a considerable ransom; after which, pretending that the captive had made his escape, fresh sums were demanded from Ptolemy for defraying the expenses of the war. For these sums Ptolemy was again obliged to apply to Rabirius, who lent him what money he wanted, on exorbitant interest; but at last Archelaus was defeated and killed, and thus Ptolemy again became master of all Egypt.

No sooner had Auletes regained possession of the throne, than he put to death his daughter Berenice, and oppressed his people by the most cruel exactions, in order to raise the money he had been obliged to borrow whilst in a state of exile. These oppressions and exactions the Egyptians bore patiently, being intimidated by the garrison which Gabinius had left in Alexandria. But notwithstanding the heavy taxes which Ptolemy laid on his people, it does not appear that he had any serious intention of paying his debts. Rabirius, who, as we have already observed, had lent him immense sums, finding that the king affected delays, undertook a voyage to Egypt in order to expostulate with him in person. But Ptolemy paid little regard to his expostulations, and excused himself on account of the bad state of his finances, at the same time offering to make Rabirius collector-general of his revenues, in order that, whilst thus employed, he might indemnify himself. The unfortunate creditor accepted the employment, in the hope of recovering his debt; but soon afterwards, upon some frivolous pretence or other, Ptolemy caused him and all his servants to be closely confined. This base conduct exasperated Pompey as much as Rabirius; for the former had been in a manner security for the debt, as the money had been lent at his request, and the business transacted at his country house near Alba. However, as Rabirius had reason to fear the worst, he seized the first opportunity of making his escape, glad to escape with life from a debtor at once so faithless and cruel. To complete his misfortunes, he was prosecuted at Rome as soon as he returned, first, for having enabled Ptolemy to corrupt the senate with sums lent him for that purpose; secondly, for having debased and dishonoured the character of a Roman knight, by farming the revenues, and becoming the servant of a foreign prince; and, thirdly, for having been an accomplice with Gabinius, and sharing with him the ten thousand talents which that proconsul had received for his Egyptian expedition. But, by the eloquence of Cicero, Rabirius was acquitted; and one of the best orations to be found in the writings of that illustrious Roman was composed on this occasion. Gabinius was also prosecuted; and, as Cicero spoke against him, he very narrowly escaped death. He was, however, condemned to perpetual banishment, after having been stripped of all he was worth; and he lived in exile until the time of the civil wars, when he was recalled by Cæsar, in whose service he lost his life.

Auletes enjoyed the throne of Egypt about four years after his restoration, and at his death left his children under the tuition of the Roman people. Among the infants thus left to the protection of the republic were Cleopatra, who afterwards became so famous, and her brother Ptolemy Dionysius. As soon as these princes became of age, they were placed on the throne, and associated in the government; but their union was of short continuance, and each being supported by a numerous party, their dissensions soon terminated in a civil war. In this contest the queen was beaten, and compelled to seek refuge in Syria. But not long after her misfortune Julius Cæsar appeared in Egypt: his victory at Pharsalia had given him Rome, he was now undisputed master of the republic, and he had come to Egypt to complete his conquest by quelling the intestine commotions which had distracted that kingdom. Cleopatra lost no time in repairing to Alexandria, and having managed to obtain a secret interview with the Roman general, speedily secured his powerful favour by her arts and caresses. This able but profligate soldier immediately restored her to power, and issued a decree in the name of the senate, which in fact existed only in his own person, ordaining that Ptolemy Dionysius and his sister Cleopatra should be acknowledged as joint sovereigns of Egypt. This arrangement, however, displeased the partizans of the young king, who had recourse to a stratagem, by which Cæsar and his attendants narrowly escaped destruction. A war soon afterwards ensued; Ptolemy was defeated and killed; and the power of the Romans was established by the right of conquest, no less than by the title of guardianship.

In order to satisfy the prejudices of the Egyptians, Cleopatra was now provided with a colleague; and her youngest brother, then not more than eleven years of age, was placed beside her on the throne. Such an appointment could not possibly serve as any real restraint on the authority of the queen, or as a limitation of her power, although this was no doubt the object of the people in requiring it; but notwithstanding that the control thus established was in a great measure nominal, the apparent check was removed by the murder of the unhappy boy, who fell a victim to the remorseless jealousy which at the period in question inflamed, whilst it dishonoured, the descendants of Ptolemy Lagus. But the term of the dynasty which this great man had founded was now approaching. The murder of Julius Cæsar, and the subsequent defeat of Mark Antony, raised the fortune of Octavianus above all rivalry or competition, and at length invested him with the purple, as the acknowledged head of the Roman empire. Cleopatra, whose charms had enslaved the triumvir to his ruin, escaped by a voluntary death from the vengeance of the conqueror. Suspecting that he intended to degrade her, by assigning her a place in the train of captives who were to adorn his triumphal ascent to the capitol, the favourite of Cæsar and of Antony spared herself this ignominy by means of the friendly poison of an asp. With Cleopatra ended the line of the Greek sovereigns, and the descendants of Ptolemy Lagus, the founder of the Greek dynasty of Egypt, after having governed that country for the space of two hundred and ninety years.

From this time Egypt became a province of the Roman empire, and its history merged in that of the mighty people by whose lieutenants it was henceforth governed. Occasionally disturbed by intestine insurrections, and sometimes a prey to foreign war, it was nevertheless maintained against both domestic and external foes, until the decline of the Roman power under the successors of Augustus rendered it necessary to abandon the extremities in order to defend the heart of the empire, and to withdraw the legions from distant provinces in order to protect from the inroads of barbarians the countries situated on the Danube and the Tiber. In the beginning of the second century, the indefatigable Hadrian spent two years in Egypt, and during this stay laboured with his accustomed perseverance to revive among the natives a love of letters, and a taste for the beauties of architecture. At a somewhat later period, Severus made a similar visit to the land of the Pharaohs and Ptolemies, and, like his illustrious but eccentric predecessor, exerted himself to relieve the burdens and ameliorate the condition of the people; at the same time encouraging every attempt made to repair the ancient monuments, to replenish the libraries of Alexandria with books, and the museums with instruments and works of art, and, above all, to withdraw studious or contemplative minds from the dangerous and absurd pursuits of magic and judicial astrology. During the reigns of Claudius and Aurelian, Egypt was slightly agitated in consequence of the pretensions of Zenobia, queen of Tadmor or Palmyra, who, as a descendant of the Ptolemies, declared herself sovereign of Egypt, marched her armies to the frontiers of that country, and even gained some advantages over the Romans; but her troops being firmly opposed by the legions, at length sustained a total defeat, when the queen herself was taken prisoner and carried captive to Rome. At a subsequent period the Emperor Probus visited Egypt, where, under his auspices, many considerable works were executed; the navigation of the Nile was improved; and temples, bridges, porticos, and palaces were constructed, chiefly by the hands of the soldiers, who acted as engineers, architects, and common labourers. But on the division of the empire by Diocletian, Egypt fell into a very distracted state; Achilleus at Alexandria, and the Blemmyes, a savage race of Ethiopians, having defied the arms of Rome. Resolved to punish the insurgents, the emperor opened the campaign with the siege of Alexandria; he cut off the aqueducts which supplied the city with water, and, notwithstanding a vigorous resistance, pushed his attack with so much steadiness and effect, that at the end of eight months the besieged submitted to the mercy of the conqueror. Busiris and Coptos were even more unfortunate than Alexandria. These proud cities, one distinguished for its great antiquity, and the other remarkable for its riches, acquired by the transit of the commerce of India, having continued their resistance to the last, were carried by assault and utterly destroyed.

The introduction of Christianity into Egypt was attended by many excesses on the part of the people, and even by some commotions which endangered the stability of the government. The adherents of the ancient faith, the worshippers of Ammon, of Knouphis, and of Ptha, naturally resisted the exposure of their idols, the desecration of their temples, and the destruction of their most sacred monuments; whilst, on the other hand, the ministers of Christianity, with a zeal which far outran the limits of discretion, wantonly insulted the opinions of the idolaters, whose ignorance they disdained to enlighten, and sometimes set at defiance the authority of the civil magistrate, when interposed for the preservation of the public peace. But after the conversion of Constantine the spirit of Christianity grew milder as its ascendency became more certain, and the power of the church was effectually exerted, in co-operation with the provincial rulers, for supporting the rights of the empire, and repelling the inroads of barbarians; nor was it until a new religion sprung up in Arabia, and gave birth to a dynasty of warlike fanatics claiming a direct descent from the new Prophet, that Egypt, wrested from the hands of its European conquerors, was forced to receive more arbitrary masters, and to submit to a severer yoke.[1] At this era, when the crescent arose in its first splendour over the cross, we terminate our retrospect of the ancient history of Egypt.

SECTION II.

HISTORY OF MODERN EGYPT.

New Religion and new Conquest.—Islamism.—Its genius and character.—Progress of the Moslemin arms.—Conquest of Egypt by Amru.—Library of Alexandria burned by order of the Caliph Omar.—State of the country during the contests for the Caliphate.—Independent government established.—Achmed Ebn-Tolun and his immediate successors.—Dynasty of the Fatemite Caliphs.—Moez.—Abu-el-Mansur Barar.—Al Hakem.—Al Taher.—Al Mostanser Billah.—Proceedings and Rebellion of Bassasiri.—Defeated and killed by Togrol Beg.—Declension of the Empire of the Caliphs.—Famine and pestilence.—Intestine divisions.—Extinction of the Fatemite Caliphs.—Aladad.—Landing of the Crusaders in Egypt.—Alliance entered into between them and Shawer, Vizir of Aladad.—Nuroddin, prince of Syria.—Progress of the Crusaders.—Salah-eddin or Saladin.—Appointed Vizir by his uncle Nuroddin.—Usurps the sovereignty of Egypt.—Rebellion.—Crusade under William of Sicily.—Panic and Flight of his Army.—Damascus, Aleppo, and other places besieged and taken by Saladin.—His triumphal entry into Cairo.—Contests with the Crusaders in Palestine.—Saladin defeated.—A fleet of European ships in the Red Sea destroyed.—Great battle on the Jordan, where the Christians were defeated with prodigious slaughter.—Tiberias, Ptolemais, and other places surrendered to the Sultan.—Jerusalem also taken after a brave defence.—Loss sustained by the Christians.—Siege of Ptolemais.—Crusade under the Emperor of Germany.—Progress of the siege.—Arrival of Philip II. and Richard Cœur de Lion in the camp before Ptolemais.—Surrender of the place.—Battle of Ascalon, and defeat of Saladin.—Truce of three years, &c.—Death of Saladin.—Crusaders defeated.—Successors of Saladin.—Rise of the Mamlukes.—The Borghites, who also assumed the name of Mamlukes.—Defeated and nearly exterminated by Sultan Selim.—Form of government given to Egypt by the Sultan.—Powers conferred on the Beys.—The Mamlukes recover their ascendency, owing to the neglect of Egypt by the Turks.—Ibrahim Bey.—Ali Bey.—Syrian campaign of Ali.—His death and character.—Mohammed Bey.—Siege of Jaffa.—Pyramid of Heads.—Fall of Acre.—Death of Mohammed.—Ibrahim and Murad Beys.—Their mutual jealousies and disputes.—They agree to share the supreme power between them.—The expedition of Hassan Pasha, and re-establishment of the authority of the Porte.—Plague.—Return of Murad and Ibrahim from exile.—French Invasion of Egypt.—Origin and objects of this enterprise.—Battle of the Pyramids.—Battle of the Nile.—Bonaparte's expedition to Syria.—Jaffa.—St Jean d'Acre.—Siege of the latter place; defeat and return of Bonaparte to Egypt.—Battle of Aboukir, and destruction of a Turkish army.—Departure of Napoleon from Egypt.—Desaix's campaign in Upper Egypt.—Convention of El Arisch.—Assassination of Kléber.—Landing of the British under Sir Ralph Abercromby.—Battle of Alexandria.—Subsequent operations.—Capitulations of Cairo and Alexandria.—Policy of Great Britain in regard to Egypt.—The Beys.—Hassan Pasha.—His treacherous conduct.—Massacre of the Beys at Aboukir.—Remonstrances of the English.—Departure of the Capitan Pasha.—Kusruf.—Affairs of Egypt.—Battle of Damanhour, and defeat of Yussuf Bey.—Mehemmed Ali.—His origin and early history.—Circumstances of his rise.—Mutiny of the Albanians.—Taher Pasha.—His fall.—Mehemmed Ali and the Mamlukes.—Ali Gezaïrli.—Defeated by the Albanians and Mamlukes at Chalakan.—Projects of Mehemmed.—He foments discord among the Beys, whom he at length attacks.—Albanians ordered to return to their own country.—Mehemmed disobeys the mandate of the Porte, and is proclaimed Pasha by the people and the troops.—A body of Mamlukes enticed into Cairo and massacred.—State of affairs.—Arrival of Saleh the Capitan Pasha.—The Albanians and the people again declare in favour of Ali.—His formal investiture as Viceroy of Egypt.—The Mamlukes.—British expedition of 1807.—Affairs of Rosetta and El Hamad.—Disastrous result of the expedition.—State of affairs after the evacuation of Egypt by the British.—Position of Ali.—Destruction of the Mamlukes resolved on.—Dissimulation and treachery of the Viceroy.—General massacre of the Mamlukes.—Details of the butchery at the Citadel of Cairo.—Conduct of Mehemmed Ali throughout the affair.—Subsequent measures to complete their extermination.—The extinction of the Mamlukes as a body.—War with the Wahabis.—The Viceroy proceeds to Arabia.—Wahabis defeated.—Peace concluded.—Regular troops.—Views of the Viceroy.—Mutiny of the Albanians.—Change of system adopted.—War with the Wahabis renewed.—Capture of Derayeh, and severities of Ibrahim.—History of the formation of the Egyptian regular army.—Labours of Colonel Sèves and others.—Expedition to Upper Egypt, Dongola, and Sennaar.—Army augmented.—Capture of Mecca.—Actual force of the Egyptian army.—Schools and Colleges.—Pay, clothing, and condition of the troops.—Campaigns in the Morea.—Egyptian navy.—Its actual strength.—War with Turkey.—Campaigns in Syria, and beyond Mount Taurus.—Battle of Koniah.—Intervention of Russia.—Conclusion of Peace.—Character and designs of Mehemmed Ali.

[1] Russell's *Egypt*, pp. 91-95.

We come now to the birth of a new religion, and we also approach the era of a new conquest. Islamism, which originated in a free and warlike nation, breathed the fiercest intolerance, and enjoined the destruction of infidels. Unlike the founder of the Christian religion, who, being a simple preacher, exercised no power upon earth, Mahommed became a king, and having declared that the whole universe ought to be subjected to his sway, commanded his followers to employ the sabre to destroy the idolater and the infidel, an injunction which they were not slack in obeying. The idolaters of Arabia were soon converted or exterminated; the infidels in Asia, in Syria, and in Egypt were attacked and conquered. As soon as Islamism had triumphed at Mecca and Medina, it served as a rallying point to the different Arab tribes, who were all imbued with the fanatical spirit; and the result was, that a whole nation, actuated by one fierce impulse, precipitated itself upon its neighbours. The progress of the Arabs therefore was rapid and irresistible. Inflamed by fanaticism, their armies at once attacked the Roman empire and that of Persia. The latter was speedily subjugated; the Moslemins penetrated as far as the Oxus, obtained possession of innumerable treasures, destroyed the empire of Chosroes, and pushed their conquests beyond the limits of Persia. In Syria, the victories which they gained at Aiquadiah and Dyrmonk put them in possession of Damascus, Aleppo, Amasia, Cæsarea, and Jerusalem. By the capture of Pelusium and Alexandria they rendered themselves masters of Egypt, now wholly Coptic, and decidedly separated from Constantinople through heretical dissensions.

The conquest of this country was effected, in name of the Caliph Omar, by his able and politic general Amru Ebn-el-As. About the same time the famous library of Alexandria, which had been founded by the great Ptolemy, and which now formed the grand repository of ancient learning and science, fell a prey to the religious fanaticism of the conquerors. If, said the Caliph Omar, in ordering it to be consigned to the flames, if this library contains only what is in the Koran, it is useless; if it contains any thing else, it is dangerous. It must be confessed, that the spirit of destruction has seldom provided itself with a more convenient or comprehensive principle of self-justification. But this fact, and many others of the same nature, ought not to make us forget what we owe to the Arabian caliphs, the successors of Omar, who, so far from being actuated by such barbarous hostility to science, were constantly engaged in extending the sphere of human knowledge, and in embellishing society by the charms of their literature.[1]

The conquest of Amru, though it laid the foundation of the Saracen power in Egypt, still left that country in an unsettled state; whilst the frequent contentions for the honours of the caliphate, which ensued during the ninth century, occasionally afforded it opportunities of asserting and attempting to re-establish its independence.

---

[1] Napoleon's *Memoirs*, vol. ii. EGYPT, *Religion*. It is nevertheless possible that the successors of Mahommed may have been at first apprehensive lest the Arabs should suffer themselves to be enervated by the arts and the sciences, which were carried to so high a pitch in Egypt, Syria, and the Lower Empire. They had before their eyes the decline of the empire of Constantine, owing partly to perpetual discussions, scholastic and theological; and it is probable that this spectacle had prejudiced them against most libraries, which, in fact, were principally filled with books of this kind. But whatever may have been the immediate cause of the act which conferred such unenviable distinction on the name of Omar, it is certain that the Arabs were, for five hundred years, the most enlightened nation of the world. It is to them we are indebted for our system of numeration, our organs, solar quadrants, pendulums, and watches; and nothing can be more elegant, ingenious, or moral, than the literature which flowed from the pens of the writers of Bagdad and Bassora. (*Memoirs*, ubi supra.)

But no sooner had the struggle for supreme power been terminated by arms or by treaty, than the land of Mizraim, the inheritance of the Pharaohs and the Ptolemies, was again compelled to receive the law from the conqueror. In the year 889, an independent government was established in Egypt by Achmed Ebn-Tolun, who had rebelled against Al Mokhadi, caliph of Bagdad; and it continued to be governed by him and his successors for twenty-seven years, when it was again reduced by Al Moktasi, who had succeeded to the caliphate. In about thirty years afterwards we find it again an independent state, united with Syria under Mahommed Ebn-Taj, who had been appointed governor of these provinces. But this government was also short lived; for in the year 968 Egypt was conquered by Jawhar, general of Moez Ledinillah, Fatemite caliph of Kairwan in Barbary.

No sooner had Moez received information of the success of his general, than he prepared to take possession of his new conquest. He ordered all the gold which he and his predecessors had amassed, to be cast into ingots, and conveyed on camels' backs into Egypt; and, in order to show his determination to abandon his dominions in Barbary, and to make Egypt the place of his residence, he caused the remains of the three former princes of his race to be removed from Kairwan, and deposited in a mosque erected for that purpose in Kahira, or the City of Victory, the Grand Cairo of latter times. In order the more effectually to establish himself in his new dominions, and to fortify his conquest by all the force of religion, he suppressed the usual prayers offered up in the mosques for the caliphs of Bagdad, and substituted his own name in their stead; and this was complied with not only in Egypt and in Syria, but even throughout all Arabia, the holy city of Mecca alone excepted. The unity of Islamism was thus interrupted, and a schism originated, which continued for upwards of two hundred years, and was productive of continual anathemas, and sometimes destructive wars between the caliphs of Bagdad and of Egypt. Having thus fully established himself in his conquest, Moez died in the forty-fifth year of his age, three years after he had left his dominions in Barbary, and was succeeded by his son Abu-el-Mansur Barar, surnamed Aziz-Billah.

The new caliph having ascended the throne at the age of twenty-one, committed the management of affairs entirely to the care of Jawhar, his father's general and prime minister; and in 978 the latter proceeded to drive out Al Aftekin, the emir of Damascus; but at the end of two months the Egyptian general, who had laid siege to that city, was obliged to raise it, on the approach of an army under the command of Al Hakem, which, not being strong enough to engage in battle, he could not prevent from effecting a junction with the forces of Al Aftekin. He therefore retreated with the utmost expedition towards Egypt; but being overtaken by the two confederate armies, he was soon reduced to the last extremity, and only permitted to resume his march on condition of passing under Al Aftekin's sword and Al Hakem's lance. To this humiliating condition Jawhar was obliged to submit; and on his arrival in Egypt he advised Al Aziz to undertake an expedition in person against the combined army under the command of Al Aftekin and Al Hakem. The caliph followed his advice; and having advanced against his enemies, overthrew them with great slaughter, at the same time making Al Aftekin prisoner. Jawhar was afterwards disgraced, and died A. D. 990, and of the Hegira 381. About this time, also, Al Aziz having received intelligence of the death of the prince of Aleppo, sent a formidable army to reduce that place. But Lulu, who had been appointed guardian to the prince's son, finding himself pressed by the Egyptians, demanded assistance from the Greek emperor, who accordingly ordered a body of troops to advance to his relief. Manjubekin, general of Al Aziz, being informed of their approach, immediately advanced to give them battle, and an obstinate engagement ensued, in which the Greeks were overthrown with great slaughter. Manjubekin then pushed on the siege of Aleppo; but meeting with more resistance than he had expected, and his provisions beginning to fail, he felt himself obliged to raise the siege. Enraged at this proceeding, the caliph threatened the general with vengeance, and commanded him to resume the siege. Manjubekin obeyed, and continued the siege for thirteen months, during which time the place was bravely defended by Lulu; but at last the Egyptians, hearing that a numerous army of Greeks was on its way to relieve the city, raised the siege, and fled with the utmost precipitation. The Greeks then took and plundered some of the cities possessed by Al Aziz in Syria; whilst Manjubekin made the best of his way to Damascus, where he set up for himself. Al Aziz, informed of this revolt, marched in person with a considerable army against the rebellious general; but being taken ill by the way, he expired, in the twenty-first year of his reign and forty-second of his age.

Al Aziz was succeeded by his son Abu-el-Mansur, surnamed Al Hakem, who, being only eleven years of age, was put under the tuition of a eunuch of approved integrity. This reign is only remarkable for the madness with which the caliph was seized towards its close. This first manifested itself by edicts alike absurd and tyrannical, and at length rose to such a height that he fancied himself a god, and no fewer than sixteen thousand persons were found to acknowledge him as such. They were mostly Dararians, a new sect which sprung up about this time, and were so called from their chief, Mohammed Ebn-Ismael, surnamed Darari, who is supposed to have inspired the mad caliph with this impious notion. Darari set up as a second Moses, and did not scruple to assert that Al Hakem was the creator of the universe; for which blasphemy he was stabbed in the caliph's chariot by the hand of a zealous Moslemin. The sect, however, did not expire with its author. A disciple of his named Hamza, being encouraged by the mad caliph, spread it far and wide throughout his dominions; all the Mahommedan fasts, festivals, and pilgrimages, including that to Mecca, were abolished; and the zealous Mahommedans became greatly alarmed, supposing that Al Hakem designed entirely to suppress the worship of the true God, and introduce his own in its stead. But from this apprehension they were delivered by the death of the caliph, who at the instigation of his own sister was assassinated, in the year 1020.

Al Hakem was succeeded by his son Al Taher, who reigned fifteen years, and left the throne to a son under seven years of age, named Al Mostanser-Billah. In the year 1041, a revolt happened in Syria; but Al Mostanser having sent a powerful army into that country, reduced the rebels, and considerably enlarged the Egyptian dominions in Syria. In 1054, an adventurer named Al Bassasiri, having quarrelled with the vizir of Al Kayem, caliph of Bagdad, fled to Egypt, and put himself under the protection of Al Mostanser, who thinking this a favourable opportunity for enlarging his dominions, supplied Bassasiri with money and troops, by which means he was enabled to possess himself of Arabian Irak, and to ravage that province to the very gates of Bagdad. Alarmed at the progress made by Bassasiri, Al Kayem applied for assistance to Togrol Beg, who possessing very extensive dominions in the East, immediately complied with this request, and soon arrived at Bagdad with a formidable army. But nothing of importance happened till the year 1058, when Bassasiri, having found means to excite Ibrahim the brother of Togrol Beg to revolt, the latter was obliged to employ all his force against him. This gave Bassasiri an opportunity of seizing on the city of Bagdad, where he caused Al Mostanser to be immediately proclaimed caliph. The imperial palace was also plundered, and the caliph himself detained a close prisoner. But this success was short lived. In the year 1059, Togrol Beg having defeated his brother Ibrahim, and taken him prisoner, caused him to be strangled with a bowstring. He then marched to Bagdad, which Bassasiri abandoned at his approach; upon which the caliph Al Kayem was delivered up and immediately restored to his dignity. Bassasiri again advanced against the city; but in a battle which took place between the army of Togrol Beg and that of Bassasiri, the latter was defeated and killed. Thus the hopes of Al Mostanser were entirely frustrated; and from this period we may date the declension of the Egyptian empire under the caliphs. They had made themselves masters of almost all Syria; but as soon as Bassasiri's defeat and death were known, Aleppo revolted, and several other places followed its example. Al Mostanser sent a powerful army against the rebels, but it was entirely defeated, and his general taken prisoner.

This disaster was soon followed by others still greater. In 1066 a famine raged over all Egypt and Syria, and multitudes of people died in Cairo from want of food. Nay, to such a degree of misery were the inhabitants reduced, not only in Cairo, but throughout all Egypt, that the carcasses of those who died were sold for food at an exorbitant price, and the most loathsome animals were greedily devoured by a famishing people. The famine, as usual, was followed by the plague; and this again by an invasion of the Turks under Abu Ali Al Hasan-Naserod'dawla, the general who had been sent against the rebel chief of Aleppo, and defeated by him. The caliph was besieged in his own palace; and being in no condition to make resistance, the unfortunate prince was obliged to buy himself off at the expense of every thing valuable left in his exhausted capital and treasury. This, however, did not prevent the merciless plunderers from ravaging all Lower Egypt from Cairo to Alexandria, and committing the most horrid excesses throughout the whole of that portion of the country.

These events happened in the years 1067 and 1068. In 1069 and 1070 there occurred two other revolts in Syria; so that this country was now almost entirely lost to Egypt. In 1095 the caliph Al Mostanser died, after a reign of sixty years, and was succeeded by his son Abul Kasem, surnamed Al Mostali. The most remarkable event of this prince's reign was his taking the city of Jerusalem from the Turks in 1098; but this success was of short duration, for the Holy City was the same year taken by the Crusaders.

From this time till the year 1164, the Egyptian history presents little else than a series of intestine broils and contests between the vizirs and prime ministers, who had in a great measure stripped the caliphs of their civil power, and left them nothing but a shadow of spiritual dignity. But these contests at last led to a revolution, by which the race of Fatemite caliphs was totally extinguished.

One Shawer, having overcome all his competitors, became vizir of Al Adad, or Aladad, the eleventh caliph of Egypt. But he had not been long in possession of office when Al Dargam, an officer of rank, endeavoured to deprive him of his dignity; upon which both parties had recourse to arms, and a battle ensued, in which Shawer was defeated, and obliged to throw himself on the protection of Nuroddin, prince of Syria. The latter having received the fugitive graciously, and promised to reinstate him in his office of vizir, Shawer, as an inducement to Nuroddin to assist him more powerfully, told him that the Crusaders had landed in Egypt, and made considerable progress in the conquest of that country; and added, that in the event of being reinstated in his office, he would pay Nuroddin annually the third part of the revenues of Egypt, and besides defray the whole expense of the expedition. Nuroddin bore an implacable hatred to the Christians, and the more readily undertook an expedition against them, that he was to be well paid for his holy zeal in defence of the true faith. He therefore sent an army into Egypt under the command of Shawer, assisted by a general named Asadoddin; and as Dargam had cut off many generals whom he imagined favourable to Shawer's interest, and had weakened the military force of the kingdom, he was easily overthrown by Asadoddin, who reinstated Shawer in the office of vizir. The faithless minister, however, no sooner saw himself established in office than he refused to fulfil his engagements with Nuroddin, and thus forced Asadoddin to seize on Pelusium and some other cities. Shawer then entered into an alliance with the Crusaders, and Asadoddin was besieged in Pelusium by the combined forces of the Christians and Infidels. But Nuroddin having invaded the Christian dominions in Syria, and taken a strong fortress called Harem, Shawer and his confederates hearkened to terms of accommodation, and Asadoddin was permitted to depart for Syria.

In the mean time, Nuroddin, having subdued the greater part of Syria and Mesopotamia, resolved to make the perfidious Shawer feel the weight of his resentment. He therefore sent Asadoddin back into Egypt with a force sufficient to compel Shawer to fulfil his engagements; but the vizir took care, before the arrival of Asadoddin, to acquit himself of the obligation he had come under, and thus for the present averted the threatened danger. But it was not long until he gave Nuroddin fresh occasion to send this general against him. That prince had now driven the Crusaders almost entirely out of Syria; but he was greatly alarmed at their progress in Egypt, and offended at the alliance which Shawer had concluded with them, and which he still persisted in observing. This treaty was also thought to be contrived on purpose to prevent Shawer from being able to fulfil his promise to Nuroddin, of sending him annually a third of the revenues of Egypt. Nuroddin, therefore, in 1166, again dispatched Asadoddin into Egypt with a sufficient force, attended by his nephew Salah-eddin, or Saladin, who afterwards became so celebrated. The invaders entered the kingdom without opposition, and having totally defeated Shawer and the Crusaders, made themselves masters of Alexandria, and overran all Upper Egypt. Saladin was left with a considerable garrison in Alexandria; but after the departure of Asadoddin the Crusaders laid siege to that city, and the Syrian general was obliged to return to its relief. But the losses he had sustained in his expedition induced him to agree to a treaty with Shawer, by which he engaged to evacuate Egypt upon being paid a sum of money. No sooner had Asadoddin withdrawn, however, than Shawer entered into a fresh treaty with the Franks, by which he was to attack Nuroddin in his own dominions, whilst engaged in quelling a revolt which effectually prevented his sending more forces into Egypt. This treaty so enraged the Syrian prince, that he resolved to suspend for a time his other ambitious projects, and exert his whole strength in the conquest of Egypt.

By this time, however, the Crusaders had reduced Pelusium, and made considerable progress in Egypt, as well as in some other countries, through the divisions which reigned amongst the Mahommedan princes. Their conquests were marked by barbarities of which Infidels might well have been ashamed. Christians as well as Mahommedans were put to the sword; their prisoners were sold as slaves; and the towns which they captured were given up to be pillaged by a licentious soldiery. From Pelusium they marched to Cairo, which was then in no posture of defence, and in the utmost confusion on account of the divisions which prevailed in it. But as soon as he heard of their approach, the vizir caused the ancient quarter of the town to be set on fire, whilst the inhabitants retired into the other districts; and he also prevailed upon the caliph to solicit the assistance of Nuroddin, which, in truth, the latter was much inclined of himself to grant, as it afforded him a fair opportunity both for driving the Crusaders out of Egypt, and for seizing the kingdom to himself. With this view he had already raised an army of 60,000 horse, and on receiving Aladad's message he instantly gave them orders to march. The Crusaders had now arrived before Cairo, and so closely invested that place, that neither Shawer nor the caliph were aware of the approach of the Moslemin army which was hastening to their relief. The vizir, therefore, finding it impossible to hold out for any length of time, had recourse to his old expedient of treaties and promises; he sent the enemy 100,000 dinars, and promised them 900,000 more, if they would agree to raise the siege; terms which, as they dreaded the approach of Asadoddin, were very readily accepted by the Crusaders. The army of Nuroddin now approached the capital by forced marches, and were everywhere received with demonstrations of joy. On his arrival at Cairo, Asadoddin was invited by Aladad to the royal palace, where he was entertained in the most splendid manner; nor were Saladin and the other principal officers less magnificently treated. Shawer, also, conscious of his perfidious conduct, was not less assiduous in his attentions. But as he was believed to have formed a scheme for having the general and his principal officers seized and murdered during an entertainment, his head was struck off, and Asadoddin was made vizir in his stead. The latter did not, however, long enjoy his new dignity; for he died some months after his instalment into office, and was succeeded by the illustrious nephew of Nuroddin.

Saladin, the new vizir, was the youngest of all the grandees who had aspired to that office, and he had already given signal proofs of his valour and conduct. The circumstances which determined the caliph to give him the preference over so many competitors are not known; but it is certain that some of them were highly displeased with his promotion, and even publicly declared that they would not obey him. In order, therefore, to gain over to his interest these disappointed aspirants, Saladin found it necessary to distribute amongst them part of the treasures left by his uncle; and by means of this powerful instrument of corruption he soon governed Egypt without control, as had been customary with the vizirs before his time. Soon after his instalment into office, he also defeated and dispersed the negro guards of the royal palace, who had opposed his election; and having placed a strong garrison in the castle or citadel of Cairo, his power became firmly established.

For some time there subsisted between Nuroddin and Saladin a good understanding, which contributed in no small degree to raise the credit of the latter with the Egyptians. But in 1169 Nuroddin sent him orders to omit the name of Aladad, the caliph of Egypt, in the public prayers, and to substitute that of the caliph of Bagdad in its stead. This was not only a bold, but a dangerous attempt, as it might produce a revolt in favour of Aladad; and even if it did not, it afforded Saladin an opportunity of engrossing what small remnant of power had been left to the caliph. But Aladad was not sensible of the disgrace intended him; for when Nuroddin's orders were received, he lay on his death-bed, past all hopes of recovery. On his demise, Saladin seized all his wealth and effects, consisting of jewels of prodigious size, sumptuous furniture, a library containing a hundred thousand volumes, and many other valuable possessions. He caused his family to be closely confined in the most retired part of the palace, and either manumitted his slaves, kept them for his own use, or disposed of them to others.

Saladin had now arrived at the highest pitch of wealth, power, and grandeur. He was, however, obliged to act with great circumspection towards Nuroddin, who still continued to treat him as his vassal, and insisted on the most implicit obedience to his commands. Saladin relied chiefly for counsel on his father Ayub, a consummate politician, who, ambitious of seeing his son raised to the throne of Egypt, advised him to continue stedfast in his resolutions, and, whilst he amused Nuroddin with feigned submissions, to take every method in his power to secure to himself the possession of so valuable a kingdom. Nuroddin himself, however, was too great a master in the art of dissimulation to be easily imposed on; and though he pretended to be pleased with Saladin's conduct, he was all the while busily occupied in raising a powerful army, with which he intended the following year to invade Egypt. But whilst he was meditating this expedition, he was seized at Damascus with a distemper which put an end to his life, in the year 1173.

Though thus freed from the apprehension of so formidable an enemy, Saladin durst not yet venture to assume the title of sovereign, more especially when he saw the successor of Nuroddin at the head of a powerful army, and not less desirous than able to dispossess him. His first care, therefore, was to secure to himself an asylum in case he should be obliged to abandon Egypt; and having accomplished this object by the conquest of a considerable portion of Arabia Felix, he assumed the title of sultan or sovereign of Egypt, and was acknowledged as such by the greater part of the states. The zeal of the Egyptians for the Fatemite caliphs, however, soon produced a rebellion. The governor of a city in Upper Egypt having assembled an army of blacks, and marched into the lower country, was there joined by great numbers of other Egyptians; but Saladin dispatched his brother Malek against the insurgents, who were entirely defeated and dispersed. This, however, did not prevent another insurrection under an impostor, who pretended to be a son of the last Fatemite caliph, and who had collected a body of 100,000 men; but before they had time to do much damage, they were surprised by the sultan's forces, and entirely defeated, with the loss of nearly three fourths of their whole number.

About this time Saladin gained a considerable advantage over the Crusaders under the command of William II. king of Sicily. That prince having invaded Egypt with a numerous army, supported by a powerful fleet, had invested Alexandria both by sea and land. Saladin flew to the relief of a place the preservation of which was of so much importance to the success of his future plans, and he had mustered a force which he deemed sufficient to justify him in risking a battle; but before he had time to make the necessary dispositions, the Crusaders, seized with a sudden panic, fled with the utmost precipitation, leaving all their military engines, stores, and baggage behind them.

In the year 1175, the inhabitants of Damascus, jealous of the minister who had the tuition of the reigning prince, and governed all with an absolute sway, entreated Saladin to assume the sovereignty of that city and its dependencies; and the application was no sooner made than the sultan set out with the utmost celerity to

Damascus, at the head of a chosen detachment of seven hundred horse. Having settled affairs in that city, he appointed his brother Saif Al Islam governor, and set out for Hems, which he immediately invested. Having also made himself master of this place, he then proceeded to Hamah, which soon surrendered; but the citadel held out for some time. Saladin pretended that he accepted the sovereignty of Damascus and the other places he had conquered, only as deputy to Almalek-el-Saleh, the successor of Nuroddin, who was then under age; and that he was desirous of sending Azzoddin, who commanded in the citadel, with a letter to Aleppo, where the young prince resided. This so pleased Azzoddin that he took the oath of fidelity to Saladin, and immediately set out with the sultan's letter. But he had not been long at Aleppo before he was thrown into prison by the minister's orders; upon which his brother, who had been appointed governor of the citadel of Hamah in his absence, delivered it up to Saladin. The sultan then marched to Aleppo with a design to reduce it; but being vigorously repulsed in several attacks, he was at last obliged to abandon the enterprise. At the same time, Kamschlegin, Almalek's minister, hired the chief of the Batanists, or Assassins, to murder the sultan, and several attempts were in consequence made on his life; but happily for Saladin all of them miscarried.

After raising the siege of Aleppo, Saladin returned to Hems, which the Crusaders had invested. On his approach, however, they thought proper to retire; and the sultan then made himself master of the castle, which before he had not been able to reduce. This was soon followed by the reduction of Baalbec. And these rapid conquests so alarmed the ministers of Almalek, that, entering into a combination with some of the neighbouring princes, they raised a formidable army, with which they hoped to crush the sultan at once. Saladin, however, dreading the event of a war, offered to cede to Almalek, Hems and Hamah, and to govern Damascus only as his lieutenant. But these terms were rejected, and a battle ensued, in which the allied army were utterly defeated, and the shattered remains of it shut up in the city of Aleppo. This produced a treaty, by which Saladin was left undisputed master of Syria, excepting only the city of Aleppo and the territory belonging to it.

In 1176, Saladin having returned from the conquest of Syria, made his triumphal entry into Cairo; and having allowed his troops some time for repose, he began to encompass the city with a wall of great extent, which however he did not live to complete. Next year he led a numerous army into Palestine to operate against the Crusaders. But here his usual good fortune deserted him. His army was entirely defeated; forty thousand of his best troops were left dead on the field; and the rest, having no towns in which they could find shelter, betook themselves to the desert between Palestine and Egypt, where the greater part of them perished from want of water. Even Saladin himself seemed to have been intimidated by this disaster: for in a letter to his brother he stated that he was more than once in the most imminent danger; and that God, as he apprehended, had delivered him from peril, in order to reserve him for the execution of some grand and important design.

In the year 1182, the sultan, at the head of a formidable army, set out on an expedition to Syria, amidst the acclamations of the people. He was, however, repulsed with loss both before Aleppo and Almasel, after having spent much time and labour in besieging these places. In the mean time a powerful fleet of European ships appeared in the Red Sea, and threatened the cities of Mecca and Medina. The news of this armament no sooner reached Cairo, than Abubekr, Saladin's brother, who had been left viceroy in the sultan's absence, caused another to be fitted out with all speed, under the command of Lulu, a brave and experienced officer, who sailed in quest of the enemy. A dreadful engagement ensued, but after an obstinate resistance the Christians were defeated, and the prisoners butchered in cold blood. This proved so severe a blow to the Europeans that they never again ventured to attempt any thing in this quarter.

In 1183 Saladin continued to extend his conquests. The city of Amida in Mesopotamia surrendered after a siege of eight days; and Aleppo, which he now attacked with better success than formerly, also capitulated. After the conquest of Aleppo, Saladin took three other cities, and then marched against his old enemies the Crusaders. Having sent out a party to reconnoitre the enemy, they fell in with a considerable detachment of Christians, whom they easily defeated, taking about a hundred prisoners, with the loss of only a single man on their side. Animated by this first instance of success, the sultan drew up his forces in order of battle, and advanced against the Crusaders, who had assembled their whole army at Sephoris in Galilee. On viewing the sultan's troops, however, and perceiving that they were greatly superior in strength to what had at first been apprehended, the Christian leaders declined an engagement, nor could Saladin, with all his skill and address, force them to accept battle. But though it was found impossible to bring the Crusaders to a decisive engagement, Saladin found means to harass them greatly, and destroyed great numbers of their men; he also carried off many prisoners, dismantled three of their strongest cities, laid waste their territories, and concluded the campaign with the capture of another strong town. For three years Saladin continued to gain ground on the Crusaders, yet without obtaining any decisive advantage; but in 1187 the fortune of war turned completely against the soldiers of the Cross.

The Christians in fact now found themselves obliged to venture a battle, on account of the ravages which the sultan committed on their territories, and the encroachments which he daily made on all sides. Both armies therefore resolved to exert their utmost efforts, and a fierce and bloody battle ensued. Night prevented victory from declaring for either side; but the fight was renewed with equal obstinacy next day, and the contest still remained undecided. On the third day the sultan's men, finding themselves surrounded by the enemy on all sides but one, and on that also hemmed in by the river Jordan, so that all retreat was cut off, fought with the courage of despair, and at last gained a complete victory. Vast numbers of the Christians perished on this bloody field. A large body indeed succeeded in retiring to the top of a neighbouring hill covered with wood; but Saladin's troops having surrounded the hill, set fire to the wood, and obliged them to surrender at discretion. Some of the captives were butchered as soon as they had delivered themselves into the hands of the enemy; and others, amongst whom were Lusignan the king of Jerusalem himself, Arnold prince of Alshabek and Alkarak, the masters of the Templars and Hospitallers, and almost the whole body of the latter, were thrown into irons. So great was the consternation which this sad reverse produced amongst the Christians, that one of Saladin's men is said to have taken thirty of them prisoners, and tied them together with the cord of his tent, to prevent them from making their escape. The masters of the Templars and Hospitallers, with the knights acting under them, were brought into Saladin's presence, when he instantly ordered them to be cut in pieces. He called these warlike monks assassins or batanists; and he had been accustomed to pay fifty dinars for the head of every Templar or Hospitaller which was brought him. After the engagement Saladin seated himself in a magnificent tent, and placing the king of Jerusalem on his right hand, and Arnold prince of Alkarak on his left, he drank to the former, who was at that time ready to expire from thirst, and at the same time offered him a cup of snow water, which was thankfully received. The king then drank to the prince of Alkarak, who sat near him. But Saladin interrupted him with some warmth: "I will not," said he, "suffer this cursed rogue to drink; for that, according to the laudable and generous custom of the Arabs, would secure to him his life." Then turning towards the prince, he reproached him with having undertaken the expedition whilst in alliance with himself, and also with having intercepted an Egyptian caravan in the time of profound peace, and massacred the people of whom it was composed. But notwithstanding this, the sultan offered to grant him his life if he would embrace Mahommedanism. The disgraceful condition was however rejected, and the sultan, with one stroke of his scimitar, cut off the prince's head. This summary proceeding naturally alarmed the king of Jerusalem; but Saladin assured him he had nothing to fear, and that Arnold had brought his fate on himself by his want of common honesty.

The Crusaders being thus totally defeated and dispersed, Saladin next laid siege to Tiberias, which in a short time capitulated. He then marched towards Acca or Ptolemais, which likewise surrendered after a short siege. Here he found four thousand Mahommedan prisoners in chains, whom he immediately released; and as the inhabitants carried on a very extensive trade, he also discovered there not only vast sums of money, but likewise a great variety of valuable merchandise, all of which he seized and applied to his own use. About the same time his brother Almalek attacked and took a very strong fortress in the neighbourhood; after which the sultan divided his army into three bodies, that he might with the greater facility overrun the territories of the Christians, and thus in a short time made himself master of Neapolis, Cæsarea, Sephoris, and other cities in the neighbourhood of Ptolemais. His next conquest was Joppa, which was taken by assault after a vigorous resistance. Saladin then marched in person against Tebrien, a strong fortress in the neighbourhood of Sidon, which was also taken by assault after a siege of six days, razed to the ground, and the garrison put to the sword. From Tebrien the victorious sultan proceeded to Sidon itself, which surrendered almost on the first summons. Berytus was next invested, and yielded to the conqueror in seven days.

Saladin, proceeding with his conquests, made himself master of Ascalon after a siege of fourteen days, and then invested the city of Jerusalem. The garrison was numerous, and made an obstinate defence; but Saladin having at last made a breach in the walls by sapping, the besieged desired to capitulate. This was at first refused; but a strong representation having been made by the Christian ambassador, who threatened that if an honourable capitulation was refused them, the garrison would kill their wives and children, massacre their prisoners, commit their property to the flames, and then sally out and sell their lives as dearly as possible, Saladin immediately called a council of war, at which the general officers to a man declared it as their opinion that it would be most prudent to allow the Christians to depart unmolested. They judged according to the maxim which recommends that a bridge of gold should be made for a flying or a desperate enemy. The sultan therefore allowed the garrison to march out freely with their wives, children, and effects, upon receiving ten dinars from every man capable of paying that sum, five from every woman, and two from every young person under age; whilst for the poorer class who were unable to pay any thing, the rest of the inhabitants contributed the sum of thirty thousand dinars.

Most of the inhabitants of Jerusalem were escorted by a detachment of Saladin's troops to Tyre; and soon afterwards he advanced with his army against that place. As the port was blockaded by a squadron of five men of war, Saladin imagined that he might easily become master of it; but in this he found himself mistaken; for one morning at day-break a Christian fleet fell upon his squadron, and so entirely defeated it that not a single vessel succeeded in effecting its escape. About the same time Saladin himself was vigorously repulsed by land; and after calling a council of war, it was thought proper to raise the siege.

In 1188, Saladin, though his conquests were not so rapid and considerable as they had hitherto been, continued still superior to his enemies. He reduced the city of Laodicea and some other places, besides many strong castles; but he met also with several repulses. At length he took the road to Antioch; and having reduced all the fortresses, many of them deemed impregnable, which lay in his way, he intimidated Bohemond prince of Antioch so much that the latter desired a truce for seven or eight months; a request which, on account of the prodigious fatigues his men had undergone, and the circumstance of his auxiliaries now demanding leave to return home, Saladin was forced to comply with.

The heavy losses they had sustained, however, proved in some respects an advantage to the Christians, as they were thus obliged to lay aside those animosities which had proved the ruin of their affairs, and to act with more concert and unanimity. The brave men who had defended Jerusalem, and most of the other fortresses taken by Saladin, having retreated to Tyre, formed there a very numerous body; a circumstance which proved the means of preserving that city, and also of re-establishing their affairs. Accordingly, having received powerful reinforcements from Europe, they were enabled, in 1189, to take the field with thirty thousand foot and two thousand horse. Their first attempt was upon Alexandretta, whence they dislodged a strong body of Mahommedans, and then made themselves masters of the place with but little loss. They next laid siege to Ptolemais; but Saladin, as soon as he received intelligence of the fact, lost no time in marching to the relief of that place. After several skirmishes a general engagement followed, in which the soldan was defeated with the loss of ten thousand men. This enabled the Christians to carry on the siege with greater vigour; but so little acquainted were they with the methods of attacking strong places, that Ptolemais was enabled for two years to resist all their efforts, and was at last reduced rather by famine than by active warfare or military force.

This year the sultan was greatly alarmed on receiving intelligence that the emperor of Germany was advancing to Constantinople with an army of two hundred and sixty thousand men, in order to assist the other Crusaders. This prodigious armament, however, came at last to nothing. The multitude was so reduced by sickness, famine, and fatigue, that scarcely a thousand men reached the camp before Ptolemais. But the siege of that city was continued, though without success on the part of the Christians. They were repulsed in all their attacks; their engines were burnt with naphtha; and the besieged received supplies of provisions in spite of the utmost efforts of the besiegers, at the same time that famine and pestilence raged in the Christian camp, sometimes carrying off two hundred persons a day. But in 1191 the Christians received powerful succours from Europe. Philip II. of France, and Richard I. of England, surnamed *Cœur-de-Lion*, arrived in the camp before Ptolemais. The latter was esteemed the bravest and most enterprising of all the chiefs of the Crusade; and the spirits of the soldiers were greatly elated by the thoughts of acting under such an experienced commander. Soon after his arrival the English sunk a Mahommedan ship of large size, having on board upwards of six hundred soldiers, and a great quantity of arms and provisions, which was proceeding from Berytus to Ptolemais. Of the soldiers and the sailors who navigated this vessel, only a single person escaped, who, being taken prisoner by the English, was dispatched to the sultan with the news of the disaster. But the besieged still defended themselves with great resolution; and the king of England happening to fall sick, the operations of the besiegers were considerably delayed. On his recovery, however, the attacks were renewed with such fury that the place was every moment in imminent danger of being taken by assault. But although Saladin was informed of the condition to which it was reduced, and although it formed his principal magazine of arms, he found it impossible to march to its relief; and the inhabitants were therefore under the necessity of surrendering the place. One of the terms of the capitulation was, that the Crusaders should receive a very considerable sum of money from Saladin, upon the condition of their delivering up the Mahommedan prisoners they had in their hands; but Saladin refused to ratify this article, and, in consequence of his refusal, three thousand of those unfortunate men were slaughtered at once by orders of the king of England.

After the reduction of Ptolemais, Richard, now appointed generalissimo of the Crusaders, took the road to Ascalon, in order to besiege that place; after which he intended to make an attempt to recover Jerusalem. Saladin proposed to intercept him on his advance, and with this view placed himself in the way with an army of three hundred thousand men. On this occasion was fought one of the greatest battles of that age, or indeed of any other. After a terrible conflict, Saladin was totally defeated, with the loss of forty thousand men; and Ascalon soon afterwards fell into the hands of the Crusaders. Other sieges were subsequently undertaken with success, and Richard even approached within sight of Jerusalem; but by reason of the weakened state of his army, and the dissensions which prevailed in it, he found himself under the necessity of concluding a truce with the sultan. In the year 1192 this was accordingly agreed to, for the term of three years, three months, three weeks, three days, and three hours; and soon after it was concluded the king of England set out on his return to his own dominions.

In 1193 Saladin died, to the inexpressible grief of all true Moslemins, who held him in the utmost veneration. His dominions in Syria and Palestine were parcelled out amongst his children and relations in petty principalities. His son Othman succeeded to the throne of Egypt; but although he possessed the ambition, he wanted the enterprising genius of his father; and indeed Saladin had no successor capable of rivalling, far less eclipsing his renown. But Alcamel, to whom the sceptre devolved about the beginning of the thirteenth century, shed a lustre on his reign by repulsing the Crusaders, who for the fifth time had invaded the kingdom of the sultans. Damietta had yielded to the arms of the Christians; and, elated with their success, they advanced up the Nile, doubtless meditating the entire conquest of the country, when a general action took place, which in its issue proved disastrous, and compelled the invaders to accept a treaty, the conditions of which were more honourable to the generosity of the Moslemin conquerors than to the ability of the Christian commanders. Alcamel died at Damascus in 1238, and one of his sons, by name Aladel, was raised to the throne. But another claimant appeared in Nojmoddin, an elder brother of the deceased prince, and a bloody contest would probably have ensued, had not the young prince in the meanwhile disappeared or died. This circumstance led to the peaceable accession of Nojmoddin, who, like his predecessor, soon acquired great influence with the chiefs of the Crusade; whilst Richard, earl of Cornwall, perceiving that the sultan of Egypt possessed more power than the Syrian lords of Karak and Damascus, concluded an alliance with him, and thereby insured protection to the numerous Christian pilgrims when wending their weary way to the holy sepulchre.

Whilst affairs were thus unsettled, Nojmoddin entered Syria, resolved, with the aid of the wild tribes who roamed through the adjoining desert, to make himself master of Damascus. A battle crowned his enterprise with success, and opened a path to still more signal advantages, when Louis the Ninth of France landed at Damietta with a new host of Crusaders, and in the absence of the sultan made considerable progress, taking several towns, and forcing the inhabitants to fly into the upper part of the country. Nojmoddin, then engaged in the siege of Emessa, hastened to the relief of his subjects; but, overpowered by fatigue and anxiety, his strength failed, and he died by the way, leaving the government to his son, an inexperienced youth. Nojmoddin, however, left one who was able and willing to avenge him. Apprehending no serious opposition, the Crusaders, with their habitual want of precaution, pushed recklessly into the interior, when, to their extreme surprise, they suddenly found themselves in presence of a formidable army, raised by the exertions of the sultan's widow, the celebrated Shagir Aldor. A battle was inevitable; and Louis, compelled to fight at a disadvantage, was defeated and taken prisoner; whilst his followers, after enduring the greatest privations, were compelled to throw themselves on the compassion of the natives whose fields they had desolated, whose houses they had plundered, and whose hearths they had profaned.

The period at which we have now arrived is remarkable for the accession to power of a race of slaves, who, transformed into soldiers, became alike celebrated for their military qualities, and formidable by their exactions, to the country over which they domineered. It will be at once understood that we allude to the Mamlukes. The origin of this celebrated military caste dates from the time of Saladin. As a usurper, the sultan naturally put little confidence in the native troops; and hence, distrusting the fidelity of his subjects, he was led to place around his person a guard of foreigners, composed chiefly of slaves purchased or made captives in the provinces bordering on the western shores of the Caspian. Under succeeding sultans the power of these armed attendants was increased by new privileges; and in a short time they, like the celebrated pretorian bands at Rome, acquired or usurped the entire disposal of the sovereign authority. In the year 1250 the reigning sultan, Malek-al-Salek, was dethroned and slain by these mercenaries; in consequence of which crime the Mamlukes became sole masters of Egypt, and chose a sultan out of their own number. This was Ibeg, who, having been named regent during the minority of the young prince, married the queen-mother upon the death of that boy, and finally, supported by his companions in arms, stepped into the vacant throne.

The Mamlukes having obtained possession of the government, and neither understanding nor valuing any thing except the art of war, every species of learning soon decayed in Egypt, and barbarism in some measure resumed its ancient empire. Nor was their ascendency of long duration, notwithstanding their martial abilities. The fact is, that originally they formed but a small part of the standing forces of Egypt; and as a numerous army was necessary in a country where, according to the fundamental maxim of government, every native must be a slave, they were at first at a loss how to act, being justly suspicious of the other portions of the regular force. But at length they resolved to purchase Christian slaves, and educate them in the same way as they themselves had formerly been; and these were commonly brought from Circassia, where the people, though they professed Christianity, made no scruple of selling their children. When they had completed their military education, these soldiers were disposed of throughout the fortresses erected in the country to keep down the inhabitants; and because in their language a fort was denominated *borge*, the new militia received the name of *Borgites* or garrison-troops. By this expedient the Mamlukes hoped to secure themselves in the sovereignty; but the result proved that they were mistaken in their calculations. The old Mamlukes having become proud, insolent, and lazy, the Borgites took advantage of their degeneracy, rose upon their masters, deprived them of the government, and about the year 1382 transferred it to one of their own number, by name Barcok, under whom the Mamluke dynasty, properly so called, was brought to an end, after having endured about a hundred and twenty years.

The Borgites, as well as their former masters, now assumed the name of Mamlukes, and became famous for their valour and ferocity of conduct. They were almost perpetually engaged in wars either foreign or domestic; and their dominion lasted till the year 1517, when they were attacked by Sultan Selim. The Mamlukes defended themselves with incredible valour; but being overpowered by numbers, they were defeated in every engagement. The same year the city of Cairo was taken, after great slaughter, and the Borgite sultan was obliged to fly. But having collected all his force, he ventured a decisive battle, in which he was defeated, the most romantic efforts of valour proving unavailing against the innumerable multitude which composed the Turkish army. A great number of his troops perished on the field; and the unhappy prince himself, seeing all hope utterly gone, took shelter in a marsh, whence he was dragged by his pursuers, and soon afterwards put to death. Nor did the vengeance of the conqueror stop here. Having erected a throne on the banks of the Nile, he caused the prisoners, amounting to upwards of thirty thousand men, to be brought before him, when he ordered them to be beheaded in his presence, and their bodies to be thrown into the river. With the death of Tuman Bey, and the wholesale butchery which followed it, ended the glory, and almost the existence, of the Mamlukes, who were now everywhere hunted out and cut in pieces.

But notwithstanding these barbarous proceedings, Selim did not attempt the total extermination of the Mamlukes, though this would have been quite agreeable to the maxims of Turkish policy. He seems to have considered, that if he should establish a pasha in Egypt, with the same powers with which those of other parts were invested, such a lieutenant or viceroy would, by reason of the distance from the capital, be under strong temptations to revolt. He therefore devised a new form of government, according to which, the power being distributed amongst the different members of the state, an equilibrium might be established, and the dependence of the whole upon himself might thereby be secured. With this view he chose a divan, or council of regency, consisting of the pasha or viceroy, and the chiefs of the seven military corps. To the former, who was to be in all cases president, it belonged to notify to the council the orders of the Porte, to transmit the tribute to Constantinople, and to provide for the safety of government, both external and internal; whilst, on the other hand, the members of the council had a right to reject the orders of the pasha, or even to depose him, provided they could assign sufficient reasons for so doing; and all civil and political ordinances required to be ratified by them. From the Mamluke Beys, who presided over the provinces, were chosen the Sheikh-el-Belled, or governor of Cairo; the Janizary Aga, or commander of the janizaries; the Defterdar, or accountant-general; the Emir-el-Hadgee, or conductor of the caravan to Mecca; the Emir-el-Saïd, or governor of Upper Egypt; and the Sheikh-el-Bekheri, or governor of the scherifs. He then formed the whole body into a sort of republic; and with this view issued an edict, setting forth that a republican government was granted to the twenty-four sangiacs or governors of provinces. These were, 1. That the sovereignty of the Porte should be acknowledged by the republic, and, in token of obedience, its lieutenant should be received as the representative of the sultan; but if the said lieutenant should attempt to infringe any of its privileges, the republic might suspend him from his authority, and send to the Sublime Porte a complaint against him: 2. That in time of war the republic should provide twelve thousand troops at its own expense, to be commanded by a sangiac or sangiacs; 3. That the republic should raise annually, and send to the Sublime Porte, the sum of 560,000 aslany (afterwards augmented to 800,000, or about L.100,000), accompanied by a sangiac, who should receive an acknowledgment for the same: 4. That the same sum should be raised for the use of Medina and Kiaba or Mecca: 5. That the janizaries should not exceed fourteen thousand in time of peace, though this number might be increased in time of war: 6. That to the sultan's granaries should be sent annually a million measures of corn, 600,000 of wheat, and 400,000 of barley: 7. That, on fulfilling these articles, the republic should have a free government over all Egypt, independently of the sultan's lieutenant, but on condition of executing the laws of the country, with the advice of the moollah: 8. That the republic should be in possession of the mint as heretofore, but on condition that it should be under the inspection of the sultan's lieutenant, in order that the coin might not be adulterated: and, 9. That the republic should elect a Sheikh-el-Belled out of the number of Beys, to be confirmed by the sultan's lieutenant; and that the said Sheikh-el-Belled should be the sultan's lieutenant, and esteemed as the head of the republic. It was further provided, that if the sultan's lieutenant should be guilty of oppression, or exceed the bounds of his authority, the Sheikh-el-Belled should represent the grievance to the Porte; and in case the peace of the republic should be disturbed by foreign enemies, the sultan guaranteed it his protection free of all expense.

Thus the power of the Mamlukes, which conquest and massacre had broken, was in some measure re-established by the arbitrary will or caprice of the conqueror; and it continued to increase until at last the Turkish dominion over Egypt became little better than a species of feudal superiority, recognised in principle, but disregarded in practice. But in order to understand how this transference of authority was produced, it is necessary to attend to the manner in which the race of Mamlukes was continued and multiplied in Egypt. This was not in the ordinary way, by marriage or descent; on the contrary, during all the time the Mamlukes maintained a footing in Egypt, few of them left subsisting issue, and almost all their children perished in the first or second descent. The means by which they were perpetuated and multiplied were the same by which they were originally established, namely, by slaves brought from the country whence they originally came. From the time of the Moguls this commerce continued on the banks of the Cuban and Phasis, in the same manner as it is carried on in Africa, by wars amongst the hostile tribes, and the misery or avarice of the inhabitants, who sold their children to strangers. The slaves thus procured were first brought to Constantinople, and afterwards dispersed throughout the empire, where they were purchased by the wealthy. When the Turks subdued Egypt they should undoubtedly have prohibited this dangerous traffic; and their omitting to do so in a great measure dispossessed them of their conquest, a consummation which a series of great political errors had otherwise been long preparing. In fact, the Porte had, for a considerable time, neglected the affairs of this province, and, in order to restrain the pashas, had suffered the divan to extend its power till the chiefs of the janizaries and ayahs were left without control. The soldiers themselves, having become citizens by the marriages which they had contracted, were no longer the creatures of Constantinople; and a change introduced into their discipline still more increased these disorders. At first the seven military corps had but one common treasury; and though the society was rich, individuals, not having any thing at their own disposal, could effect nothing. But the chiefs, finding their power diminished by this arrangement, had interest enough to get it abolished, and to obtain permission to possess distinct property, lands, and villages. As these lands and villages, however, depended on the Mamluke governors, it was necessary to conciliate them, in order to prevent their exactions. From that moment the Beys acquired an ascendency over the soldiers, who till then had treated them with disdain; and this ascendency continued to increase, as their government secured to them the possession of considerable riches, which they employed chiefly in creating friends and multiplying dependents. They increased the number of their slaves; and after emancipating them, employed all their interest to obtain various employments, and procure advancement in the army. These upstarts, retaining for their patrons the superstitious veneration common in the East, formed factions implicitly devoted to their will, and were ready at all times to execute their commands.

Accordingly, about the year 1746, Ibrahim, one of the kiayas or commanders of the janizaries, rendered himself in reality master of Egypt, having managed matters so well, that of the twenty-four Beys or Sangiacs, eight were members of his own household. His influence too was augmented by always leaving vacancies in order to draw the emoluments himself, whilst the officers and soldiers of his corps were attached to his interest; and his power was completed by gaining over to his interest Rodohan, the most powerful of all the chiefs. Thus the pasha became altogether unable to oppose him, and the orders of the sultan were much less respected than those of Ibrahim. On his death in 1757, his family, that is, his enfranchised slaves, continued to rule in a despotic manner. But having quarrelled amongst themselves, Rodohan and several other chiefs fell in the contests which ensued, and the utmost anarchy and confusion prevailed.

In 1766, while matters still continued in this state, Ali Bey, who had been a principal actor in the disturbances, gained a decided superiority over his rivals, and, under the successive titles of Emir-el-Hadgee, and Sheikh-el-Belled, he rendered himself absolute master of Egypt. The birth of Ali Bey, like that of the Mamlukes in general, is extremely uncertain. It is commonly believed that he was born among the Abazans, a people of Mount Caucasus, who, next to the Circassians, are most valued by the Turks as slaves; and that having been brought to a public sale at Cairo, he was purchased by two Jews, brothers, named Isaac and Yussuf, who presented him to Ibrahim Kiaya. At this time he is supposed to have been about thirteen or fourteen years old; and he was employed by his patron in offices similar to those of the pages belonging to European princes. The usual education of Mamlukes was also given him. He was taught to manage a horse adroitly; to fire a carbine or pistol with a sure aim; and to throw the djereed, a kind of dart or javelin used in the diversions of the country. He was also instructed in the exercise of the sabre, and taught a little reading and writing. In all feats of activity he discovered such fire and impetuosity, that he obtained the surname of Djendali or Madman; and as he grew up he discovered an ambition proportioned to the activity displayed in his youth, but which served to moderate and restrain the ardour of his disposition. About the age of eighteen or twenty he received his freedom, and his kind patron also promoted him to the rank of kiachef or governor of a district, and at last elected him one of the twenty-four Beys, at once the tyrants and oppressors of the unhappy Fellahs.

The death of Ibrahim in 1757 afforded him an opportunity of satisfying his ambition; and he now engaged in every scheme connected with the promotion or disgrace of the chiefs, and had a principal share in the ruin of Rodohan Kiaya, as already mentioned. The post of Rodohan was quickly filled by another competitor for his dangerous office, who, however, did not long enjoy his elevation; and in 1762 Ali Bey, who was then styled Sheikh-el-Belled, having caused Abderrahman, the real possessor of the office, to be exiled, managed to get himself elected in his stead. But he soon shared the fate of the rest, and was condemned to retire to Gaza. This place, however, being then under the dominion of a Turkish pasha, proved by no means either agreeable to or safe for Ali, who accordingly betook himself to another asylum, where he remained concealed until 1766, when his friends at Cairo procured his recal. On this he appeared suddenly in that city, killed four of the Beys who were inimical to his designs, banished the rest, and assumed the whole power. Still, however, his ambition was not satisfied. Indulging the loftiest aspirations of ambition, he determined to throw off his dependence on the Porte, and to declare himself sultan of Egypt. With this view he expelled the pasha, refused to pay the accustomed tribute, and, in the year 1768, proceeded to coin money in his own name. The Porte being at that time on the eve of a war with Russia, had not leisure to attend to the proceedings of Ali; so that the rebel chief had leisure and opportunity for forwarding his enterprise. His first expedition was directed against an Arabian prince named Hammam, under pretence that the latter had concealed a treasure entrusted to him by Ibrahim Kiaya, and that he had afforded protection to rebels. The command of the expedition he entrusted to his favourite Mohammed Bey, by whom the unfortunate prince was destroyed, and his territories despoiled. Ali next set about executing a plan which had been proposed to him by a young Venetian merchant, for rendering Djidda, the port of Mecca, an emporium for all the commerce of India; and he even imagined that he would succeed in causing the Europeans to abandon the passage to the East Indies by the Cape of Good Hope. With this view he fitted out some vessels at Suez; and having manned them with Mamlukes, commanded Hassan Bey to sail with the squadron for Djidda, and attack it, whilst a body of cavalry under Mohammed Bey advanced against the town. Both these operations were executed to his wish, and Ali became quite intoxicated with his success. Nothing but ideas of conquest now occupied his mind; and without considering the disproportion between his own force and that of the Grand Signior, he never once doubted that he would be able to maintain himself against all the power of the Porte. And circumstances, it must be owned, were at this time favourable to his designs. Sheikh Daher was in rebellion against the Porte in Syria, and the pasha of Damascus had so exasperated the people by his extortions that they were ready for revolt. Having therefore made the necessary preparations, Ali, in 1770, dispatched about five hundred Mamlukes to take possession of Gaza, and thus to secure an entrance into Palestine. When Osman, pasha of Damascus, heard of the invasion, he prepared for war with the utmost diligence; whilst the troops of Ali Bey were, it is said, ready to fly at the first attack. But they were relieved from their embarrassment by Sheikh Daher, who hastened to their assistance; and Osman, dreading to encounter both, fled without offering the least resistance, thus leaving the enemy masters of Palestine. About the end of February 1771 the army of Ali Bey was put in motion. Its numbers have been variously represented, but it is probable that, including camp followers, a very numerous class in the East, it exceeded forty thousand men. This force, or rather armed multitude, commanded by Mohammed Bey, the friend of Ali, took the road to Acre, leaving wherever they passed frightful traces of their rapacity and want of discipline. At Acre a junction was formed with the troops of Sheikh Daher, consisting of fifteen hundred Safadins; Sheikh Daher's subjects being so called from Safad, a village of Galilee, originally under his jurisdiction. These were on horseback, and accompanied by twelve hundred Motualis cavalry under the command of Sheikh Nasif, and about a thousand Moggrebin infantry. Thus they proceeded towards Damascus, whilst Osman prepared to oppose them by another army equally numerous and ill regulated.

The military operations in Syria in the year 1771 have been described by Volney. The combined army of Ali Bey and Sheikh Daher marched to Damascus. The pashas waited for them; they approached, and, on the 6th of June, a decisive action took place. The Mamlukes and Safadins rushed on the Turks with such fury, that, terrified at their onset, the latter immediately took to flight, and the pashas were not the last in endeavouring to make their escape. The allies became masters of the country, and took possession of the city without opposition, there being neither walls nor soldiers to defend it. The castle alone resisted. Its ruined fortifications had not a single cannon, much less gunners; but it was surrounded by a muddy ditch, and behind the ruins were posted a few musketeers, who alone were sufficient to check this army of cavalry. As the besieged, however, were already conquered by their fears, they capitulated on the third day; and the place was to be surrendered next morning, when at daybreak an extraordinary revolution took place.

This was the defection of Mohammed Bey himself, whom Osman had gained over in a conference during the night. At the moment, therefore, when the signal of surrender was expected, this treacherous commander sounded a retreat, and turned towards Egypt with all his cavalry, flying with as great precipitation as if he had been pursued by a victorious army. Mohammed continued his march with such celerity that the report of his arrival in Egypt reached Cairo only six hours before himself. Thus Ali Bey found all his expectations of conquest disappointed, and a traitor whom he durst not punish at the head of his forces. A sudden reverse of fortune now took place. Several vessels laden with corn for Sheikh Daher were taken by a Russian privateer; and Mohammed Bey, whom he designed to put to death, not only made his escape, but was so well attended that he could not be attacked. As his followers continued to increase daily in number, Mohammed soon became sufficiently strong to march towards Cairo; and in April 1772, having defeated the troops of Ali in a rencounter, he entered the city sword in hand, whilst the latter had scarcely time to make his escape with eight hundred Mamlukes. Ali proceeded to Syria, which he reached with difficulty, and immediately joined Sheikh Daher with the troops which accompanied him in his flight. The Turks under Osman were at that time besieging Sidon, but they raised the siege on the approach of the allied army, consisting of about seven thousand cavalry. Though the Turkish army was at least three times this number, the allies did not hesitate to attack them; and having gained a complete victory, their affairs now began to wear a more favourable aspect.

In the beginning of 1773, Jaffa, a place which had revolted, capitulated, and Ali Bey began to think of returning to Cairo. For this purpose Sheikh Daher promised to furnish him with fresh succours; and the Russians, with whom he had now contracted an alliance, made him a similar promise. But Ali ruined every thing by his own folly and impatience. Deceived by an astrologer, who pretended that the auspicious moment indicated by the stars had just arrived, and also misled by false information insidiously conveyed to him by the agents of Mahommed, who caused letters to be written to him urging his immediate return to Cairo, he set out with his Mamlukes and about fifteen hundred Safadins sent him by Daher, without waiting for further aid; but he had no sooner entered the desert which separates Gaza from Egypt, than he was attacked by a body of a thousand chosen Mamlukes who were waiting his arrival. They were commanded by a young Bey named Murad, who being enamoured of the wife of Ali Bey, had obtained a promise of the lady from Mohammed, in case he should bring him her husband's head. As soon as Murad perceived the dust which announced the approach of Ali Bey's army, he rushed upon the advancing force, defeated it, and took Ali Bey himself prisoner, after wounding him in the forehead with a sabre. Being conducted to the presence of Mohammed Bey, Ali was treated by the latter with every appearance of respect, and a magnificent tent was ordered to be erected for him; but in three days thereafter he was found dead, of his wounds, as was given out, though some affirm, perhaps with good reason, that he was poisoned.

After the death of Ali, Mohammed Bey became undisputed master of Egypt; but to the people this change of despots proved to be one from bad to worse. At first he pretended to defend the rights of the sultan; he remitted the usual tribute to Constantinople, and he took the customary oath of unlimited obedience; after which he solicited permission to make war against Sheikh Daher, the ally of Ali Bey. This request, although springing out of personal animosity, was nevertheless granted, and Mohammed made diligent preparations for war. Having procured a considerable train of artillery, he provided foreign gunners, whom he placed under the orders of an Englishman named Robinson; and, having completed the necessary preparations, he, in the month of February 1776, appeared in Syria with an army equal in number to that which he had formerly commanded when in the service of Ali Bey. Daher's forces, unable to cope with so formidable a body, abandoned Gaza, which Mohammed immediately took possession of, and then marched towards Jaffa, the ancient Joppa, situated on a part of the coast the general level of which is very little above that of the sea. The city is built on an eminence in the form of a cone, and about a hundred and thirty feet in height. The houses distributed on the declivity rise above one another like the steps of an amphitheatre; and on the summit is a small citadel, which commands the town; whilst the bottom of the hill is surrounded by a wall without a rampart, of twelve or fourteen feet in height and two or three feet in thickness, but without a ditch, and environed by gardens. The city was defended by five or six hundred Safadins and as many inhabitants, who had only a few brass cannon, twenty-four pounders, without carriages, which they mounted as well as they could on timbers prepared in a hurry.

Mohammed, finding he must have recourse to force, formed his camp before the town, in the most irregular and disorderly manner possible. Batteries were now erected upon a rising ground at the distance of about two hundred yards from the town, and the bombardment commenced. A wall only three feet thick, and without a rampart, was soon breached even by the ill-served artillery of Mohammed, and the Mamlukes advanced on foot to the assault; but the besieged coolly waiting till they arrived at the empty space between the city and wall, assailed them from the terraces and windows of the houses with such a shower of bullets, that the assailants retired, under a persuasion that the breach was utterly impracticable. Murad Bey brought them several times back to the attack, but all his efforts were vain. Six weeks passed in this manner; and Mohammed, distracted with rage, anxiety, and despair, had thoughts of abandoning the enterprise. But fortunately for him, the besieged, whose numbers were diminished by the repeated attacks, became weary of defending the cause of Daher; and some persons having begun to treat with the enemy, it was at length proposed to abandon the place, upon the Egyptians giving hostages. Conditions were agreed upon, and the treaty was on the point of being concluded, when, in the midst of the security which this circumstance occasioned, some Mamlukes entered the town. Numbers followed their example, and attempted to plunder; the inhabitants defended themselves, and the attack recommenced. The whole army then rushed into the town, which suffered all the horrors of a successful assault; men, women, and children, young and old, were indiscriminately cut in pieces; and Mohammed, equally mean and barbarous, caused a pyramid, formed of the heads of these unfortunate sufferers, to be raised as a monument of his inglorious victory.

This disaster everywhere diffused the greatest terror and consternation. Sheikh Daher fled, and Mohammed soon afterwards became master of Acre, where he behaved with his usual cruelty, and abandoned the city to pillage. The French merchants claimed an exemption, which was obtained with the utmost difficulty, and, but for a fortunate accident, would have been of little consequence. Being informed that the treasures of Ibrahim, the kiaya of Daher, had been deposited in that place, Mohammed immediately demanded them, threatening the merchants with death if they were not instantly delivered up; and a day was appointed for making the search; but before it arrived the tyrant had caught a malignant fever, of which he died after a short illness. When his death became known, the army, aware of the vengeance it had provoked, and being now without a head, made a precipitate and tumultuous retreat. This event occurred in the summer of 1776. Sheikh Daher continued his rebellion for some time, but he was at last entirely defeated, and his head sent to Constantinople by Hassan, the Turkish capitan-pasha or high admiral.

As soon as the news of Mohammed's death reached Egypt, Murad Bey hastened to Cairo in order to dispute the sovereignty with Ibrahim Bey, who had been entrusted with the government on the departure of Murad for Syria. Preparations for war were in consequence made on both sides; but at last, finding that the contest would be attended with equal difficulty and uncertainty, they came to an accommodation, by which it was agreed that Ibrahim should retain the title of Sheikh-el-Belled, and that the power which neither was inclined to relinquish should be divided between them. But the Beys and other chiefs who had been promoted by Ali Bey, perceiving their own importance totally annihilated by this duumvirate, resolved to shake off the yoke, and therefore united in a league for supporting what they were pleased to term the house of Ali Bey. This combination was managed with so much silence and dexterity, that both Murad and Ibrahim were obliged to abandon Cairo. In a short time, however, having collected reinforcements, they returned and defeated their enemies; but notwithstanding this success, they were unable altogether to suppress the party which had been formed against them. A new combination was formed among the Beys, five of whom were sentenced to banishment in the Delta. They pretended to comply with this order, but took the road through the desert of the Pyramids, and, though they were pursued for three days, arrived safe at Minieh, a village situated on the Nile, forty leagues above Cairo. Here they took up their residence, and being masters of the river, soon reduced Cairo to distress by intercepting its provisions. A new expedition, therefore, became necessary, and Ibrahim took the command upon himself. In the month of October 1783 he set out with an army of three thousand cavalry, and the two armies soon came in sight of each other; but Ibrahim thought proper to terminate the affair by negociation. This gave great offence to Murad, who, suspecting some design against himself, immediately left Cairo. A war between the two sovereign colleagues seemed now inevitable, and the armies continued for twenty-five days in sight of each other, being only separated by the river. But negociations were at length opened; and the five exiled Beys, finding themselves abandoned by Murad, took to flight. They were however pursued and brought back to Cairo, and peace appeared to be re-established on a better footing than heretofore; but the jealousy of the two rivals having produced new intrigues, Murad was once more obliged to leave Cairo in 1784. He encamped, however, at the very gates of the city; and Ibrahim, dreading his power, or overawed by his boldness, found himself obliged in his turn to retire to the desert, where he remained till March 1785. A new treaty was then entered into, by which the rivals agreed to share the supreme power between them; an arrangement which certainly afforded but little prospect of lengthened tranquillity.

Matters were in this situation, when, in 1786, the Porte, having concluded a peace with Russia, resolved to reduce Egypt once more to a state of subjection and obedience. With this view, Hassan Pasha, famous for his exploits in the Morea and in Cyprus, was dispatched by the sultan at the head of a force amounting to twenty-five thousand men. Having effected a landing at Alexandria in the month of July, Hassan made instant preparations for advancing towards Cairo. But he was met near Mentorbes by Murad at the head of his Mamlukes, and a furious battle immediately ensued. The victory, however, remained with Hassan. The ground being still soft from the effects of the inundation, the Mamlukes, whose horses sunk in the mud, were unable to charge with their accustomed impetuosity, and the Turkish infantry thus gained a decided advantage. Had it not been for this fortunate circumstance, Hassan might have been shorn of some of his laurels in contending with that superb cavalry, by far the finest and most enterprising in all the East. As it was, Cairo opened its gates to the victorious pasha, who, after appointing a governor, continued his march in pursuit of the Beys into the Saïd. But finding the power of these chiefs still in some measure unbroken, and experiencing great difficulties in subsisting his army in the face of an active and vigilant enemy, Hassan was induced, in the course of the following year, to accede to a treaty, by which the Beys were left in full possession of the country from Barbieh to the confines of Nubia, upon condition of their relinquishing all claims to the territory below the place just mentioned. By this arrangement, he freed Lower Egypt from the exactions of the Mamlukes, and secured to the inhabitants of that part of the country the benefit of something like a settled government. He also applied himself to lighten their burdens, to redress their grievances, and to fortify Cairo so as to enable it to hold out against any sudden inroad of the disaffected Beys; and his whole conduct indeed was alike distinguished for wisdom and moderation. But, in 1790, the plague appeared in its most virulent type; and after committing frightful ravages amongst the lower classes, who in all countries, and particularly in Egypt, are the first victims of a pestilence, it put an end to the life of Hassan Pasha. By this event the authority which had kept the Mamlukes in check was annihilated; and, after a short interval, during which an attempt was made to confirm the authority of the Porte, Murad and Ibrahim returned from exile, and once more assumed the sovereign power, in defiance of all the menaces of the divan.

But the domestic contentions by which Egypt had so long been distracted were now to be succeeded by foreign invasion. From an exaggerated notion of the importance of the British dominions in the East, which were regarded as a source of inexhaustible wealth to this country, the possession of Egypt, the channel through which the commerce of India anciently flowed into Europe, had long been viewed by the statesmen of France as a most desirable acquisition for that country. Various arguments, some of them plausible enough, were accordingly advanced in support of this conclusion. In particular, it had been contended that the communication between India and the southern parts of Europe, by the channel of the Red Sea, was the shortest, the safest, and the most economical; that the Nile might be connected with the Arabian Gulf by means of a canal cut across the isthmus of Suez; that, independently of the commerce of India, the country on the eastern shores of the Red Sea abounded in spices, perfumes, and other valuable products; that Africa had gold dust and ivory to give in exchange for the more bulky commodities of Europe; and therefore that Egypt, if occupied by one of the maritime powers of the Mediterranean, would prove a more valuable possession than all the British territories in India. From the time of Leibnitz, who addressed to Louis XIV. a memorial recommending the occupation of Egypt for the purpose of destroying the maritime and commercial ascendency of the Dutch, the speculation which he had in some measure originated continued to find favour with the statesmen of France; and when the naval pre-eminence of Britain, which a series of unexampled triumphs had placed on a firm basis, put an end to all hope of disputing with her the empire of the ocean, or again establishing a footing in India by means of armies transported by fleets, the project of seizing upon Egypt began to be anxiously discussed and seriously meditated. Nor was this scheme viewed merely in connection with objects of commercial enterprise, or even the extension of the colonial possessions of France. To the bold and ardent minds that now predominated in the French councils, it promised other and still more important advantages. The subjugation of Egypt by a nation whose territory bordered on the Mediterranean was considered as the most effectual blow which could be struck against the power of Turkey; whilst, by occupying that country with a powerful military force, and, as a necessary consequence, adding to it the possession of Syria, a position would be obtained from which the British possessions in India might be threatened, and perhaps in due time attacked. Ideas the most gigantesque were formed, and to men flushed with the confidence inspired by victory all things seemed possible.

It is not certainly known with whom originated the project of sending an expedition at this time to Egypt, and various persons have claimed or received the merit of the suggestion. It is beyond all doubt, however, that the ardent mind of Napoleon entered into the scheme with characteristic energy,[1] and that the executive directory acquiesced in it with a readiness which perhaps arose as much from policy as conviction. The young soldier of Italy had already become too great for a republic. In a country which had recently witnessed so many revolutions, and where all distinctions are so liable to be eclipsed by military glory, the man who had dictated to Austria the preliminaries of Leoben could not but be an object of dread to a feeble and unpopular government; and hence it is at least a reasonable presumption, that the immediate advantage of removing to a safe distance a dangerous army and a still more dangerous military chief, weighed fully as much with the executive directory as any of the speculations to which we have alluded.

But be this as it may, an expedition was fitted out with all possible secrecy, and on the 18th May 1798 it sailed from Toulon. The squadron consisted of thirteen sail of the line, six frigates, and a dozen brigs, sloops, and cutters, having on board about forty thousand men of all arms, under the command of Napoleon, who had been named general-in-chief of the army of the East. After doubling Cape Corso and Cape Bonara, the expedition arrived on the 10th of June before Malta, which, through the degeneracy of the knights, surrendered almost without resistance; and having left a garrison in the island, it next steered for the coast of Egypt, which, after narrowly escaping an encounter with the British fleet under Lord Nelson, it reached on the 1st of July. The troops were immediately landed near Alexandria, and on the evening of the 5th that place was carried by assault. The general-in-chief then passed several days in laying down the principles on which the city was to be fortified; and, in a short time, a complete system of works, capable of a long defence, was formed under the able superintendence of the principal French engineers.

---

[1] Napoleon has himself explained the views with which this expedition was undertaken. "There were three objects," says he, "in the expedition to Egypt: 1*st*, To establish a French colony on the Nile, which would prosper without slaves, and serve France instead of the republic of St Domingo and of all the sugar islands; 2*dly*, To open a market for our manufactures in Africa, Arabia, and Syria, and to supply our commerce with all the productions of those vast countries; 3*dly*, Setting out from Egypt as from a place of arms, to lead an army of 60,000 men to the Indus, to excite the Mahrattas and oppressed people of those extensive regions to insurrection. Sixty thousand men, half Europeans, and half recruits from the burning climates of the equator and the tropics, carried by 10,000 horses and 50,000 camels, having with them provisions for fifty or sixty days, water for five or six days, and a train of artillery of a hundred and fifty field-pieces, with double supplies of ammunition, would have reached the Indus in four months. Since the invention of shipping the ocean has ceased to be an obstacle, and the desert is no longer an impediment to an army possessed of camels and dromedaries in abundance. The first two objects were fulfilled, and, notwithstanding the loss of Admiral Brueys' squadron at Alexandria, the intrigue by which Kléber was induced to sign the convention of El-Arisch, the landing of from 30,000 to 35,000 English commanded by Abercromby at Aboukir and Cosseir, the third object would have been attained; a French army would have reached the Indus in the winter of 1801-1802, had not the command of the army devolved, in consequence of the murder of Kléber, on a man who, although abounding in courage, talents for business, and good-will, was of a disposition wholly unfit for any military command." (*Memoirs*, vol. ii. part 2, p. 205.)

Having given the necessary directions, and made suitable preparations, Napoleon left Alexandria to advance against the Mamlukes, who had resolved to dispute his passage towards Cairo; at the same time repeating to Admiral Brueys, who commanded the French squadron, the order previously given to enter the port of Alexandria, or, in case he should consider that impossible, to proceed to Corfu or Toulon. The first encounter with the Mamlukes took place at Shebreis on the 13th July. Here they waited the approach of the French army, which was drawn up so that each division formed a square, with the baggage in the centre; and they soon spread over the whole plain, outflanking the wings, and seeking on all sides a weak point to enable them to break the French line; but finding it everywhere equally formidable, and being opposed with a double fire from front and flank, they were compelled to retire with loss, after having made several fruitless attempts to charge. The French army then continued its advance, and was approaching Cairo, when information reached the general-in-chief that the Mamlukes, combined with the troops of that city, and with a considerable number of Arabs, janizaries, and spahis, were waiting for them between the Nile and the Pyramids covering Ghizeh, where they boasted that the success of the invaders would terminate. Napoleon halted a day at Omedinar, to afford the troops some repose, and enable them to get their arms in readiness, and to prepare for battle. On the 21st, at one in the morning, the army marched from Omedinar, and at ten perceived Embabeh, and the enemy in line. Their right was supported on the Nile, where they had traced out a large entrenched camp, lined with forty pieces of cannon, and defended by about twenty thousand infantry, consisting of janizaries, spahis, and militia from Cairo. On this entrenched camp the Mamluke cavalry, amounting to between nine and ten thousand horse, rested its right, and extended its left in the direction of the Pyramids, crossing the road to Ghizeh; whilst two or three thousand Arabs maintained the extreme left, and occupied the space between the Mamlukes and the Pyramids. These dispositions were formidable. But Napoleon, discerning that the intrenched camp was merely sketched out, and that the cannon were mounted on field carriages, and consequently immoveable, concluded that the infantry would not quit the intrenched camp, or that if they came forth it would be without artillery. On these data he made his dispositions for battle; resolving to prolong his right, and to follow the movement of that wing with his whole army, at the same time passing out of the range of the guns of the intrenched camp. Murad Bey, who commanded in chief, quickly divined the purpose of his antagonist; and comprehending at once that the fortune of the day depended on preventing the French from executing this movement, and availing himself of his numerous cavalry to attack them on their march, he advanced at the head of about two thirds of his horse, amounting to between six and seven thousand, and fell upon General Desaix, who was moving forward by the extremity of the French right. The charge was made with such rapidity that Desaix was for a moment compromised, and the squares appeared to be falling into confusion. But as the head of the corps of Mamlukes was not numerous, and the mass did not arrive for some minutes, the delay was sufficient to enable Desaix to complete the formation of the squares, and to receive the charge with coolness. Regnier supported Desaix on the left, whilst Napoleon, marching on the main body of the Mamlukes, placed himself between the Nile and Regnier. The Mamlukes were received with discharges of grape and musketry, and some of the bravest died almost on the bayonets of Desaix's division; but the mass, by an instinct natural to horse, turned round the squares, and this frustrated the charge. In the midst of the fire, the dust, and the smoke, part of the Mamlukes regained the intrenched camp, against which the divisions of Bon and Menou immediately advanced, whilst General Rampon with two battalions occupied a defile between Ghizeh and the camps. The most horrible confusion now prevailed at Embabeh. The cavalry had thrown itself upon the infantry, which, seeing the Mamlukes beaten, rushed into the djerms, caiques, and other boats, in order to pass the Nile; then the Mamlukes, perceiving that their retreat was in the wrong direction, attempted to regain the Ghizeh road, but were driven back by Rampon's battalions on the intrenched camp, where many of them fell. But many more were drowned in attempting to pass the Nile; and the intrenchments, artillery, pontoons, and baggage, all became the prize of the conquerors. Of this army of above sixty thousand men, not more than two thousand five hundred horse escaped with Murad Bey. Ibrahim fled into the eastern parts of the Delta, whilst Murad, with the remnant of his Mamlukes, retreated into the desert beyond Sakbara.[1]

But this victory was speedily counterbalanced by a signal overthrow which the French experienced at sea. Admiral Brueys, neglecting or disregarding the orders given by Napoleon to enter the port of Alexandria, had moored his squadron, for defending the entrance of Aboukir Bay, in a line of battle, flanked by numerous gun-boats, four frigates, and a battery of guns and mortars on an island in their van. But this position, though strong, had a defect of which the quick eye of Nelson enabled him to take decisive advantage. On the 1st of August this great commander appeared off the mouth of the Nile with a squadron equal in force to that of the enemy, and instantly directed his course towards him. The French ships were at single anchor, with springs on their cables, and riding with their heads to wind, which was from the north-west. On this circumstance the plan of attack was formed. About half the British ships got between the enemy and the shore, either by cutting through their line or sailing round the head of it; and the rest attacked on the outside. All dropped their anchors close alongside of their opponents; and by this disposition some of the French line were doubled on, whilst all engaged on the land side were taken unprepared. The battle began about six in the evening, and was long and obstinately contested. After it had lasted several hours, the L'Orient of 120 guns, which carried the French admiral's flag, blew up with a terrible explosion, but not until the six headmost ships had surrendered. Next morning at daylight the action recommenced; but, with the exception of two sail of the line and two frigates which escaped, the other ships were either taken or destroyed. Never indeed was victory more complete. Of thirteen sail of the line, nine were captured and two destroyed, the Timoleon having shared the same fate as the L'Orient. The loss on the part of the French was necessarily great. Upwards of 5200 perished, and 3105, including wounded, were sent ashore by cartel. The British loss in killed and wounded amounted to 895. Westcott was the only captain who fell.

---

[1] It was at the commencement of the battle of the Pyramids that Napoleon addressed to his soldiers the words which afterwards became so famous: "From the tops of these Pyramids forty centuries look upon you."

After Cairo had surrendered to the French, Bonaparte formed his army into three divisions, one of which, commanded by General Desaix, was sent into Upper Egypt in pursuit of the Mamlukes; another was left for the defence of Cairo; and at the head of the third he marched in person in pursuit of Ibrahim Bey, who had taken his route towards Syria with a rich caravan. In order to render abortive the designs of Bonaparte, Britain formed an alliance with the Porte; and the chief preparations for carrying the concerted plan into effect were made in Syria, under the direction of Djezzar, pasha of Acre. The frontiers of Egypt towards Syria were to be attacked by an army from Asia Minor; and this operation was to be seconded by making a strong diversion towards the mouths of the Nile, and by various attacks in Upper Egypt with the remains of Murad Bey's cavalry. Sir Sidney Smith left Portsmouth to superintend the execution of this extensive plan, and to afford every assistance in his power by means of the maritime force under his command. In the mean time, the harbour of Alexandria was blockaded by a force of four sail of the line and five frigates, under the command of Sir Samuel Hood; it having been found impracticable to burn or destroy the French fleet of transports, without the assistance of a land force sufficient to attack Alexandria.

In order to destroy the preparations of the Djezzar Pasha, and disconcert the plans of Sir Sidney Smith, General Bonaparte resolved to leave Egypt and march into Syria; and although the result of the expedition proved disastrous to the French interest, yet Bonaparte perhaps never undertook an enterprise with more rational expectations of ultimate success. The town of Jaffa, the ancient Joppa, was obstinately defended, but at last yielded to the superiority of European tactics. From this place the French general marched with his army in three divisions against St Jean d'Acre, to which he immediately laid siege. But the pasha was powerfully encouraged to make an obstinate resistance, by Sir Sidney Smith, who appeared off Acre with the Tigre and Theseus seventy-fours, and some smaller vessels; and in order to animate him still more, he sent a French engineer of distinguished merit, through whose means Sir Sidney had himself been enabled to effect his escape from the Temple. But although the fortress had been repaired by Colonel Philippeaux, the engineer alluded to, yet it is more than probable that it could not have long held out against the skill and intrepidity of Napoleon, had not his heavy artillery, and siege equipage of every kind, been intercepted by the British, whilst on their way from Jaffa. After a protracted and bloody siege of sixty-one days continuance, during which the French had repeatedly mounted the breach, and been on the very eve of succeeding in their attempts, having in the last assault effected a lodgment in a tower within the body of the place, Napoleon was obliged to abandon all hope of reducing Acre, the garrison of which had been strongly reinforced, and, after sacrificing his heavy artillery, to commence his retreat towards Egypt. The siege began on the 20th of March, and was raised in the night between the 20th and 21st of May 1799. The French army retreated by Kantura, Cæsarea, Jaffa, and Gaza; then crossed the desert, and stopped at El-Arisch, where Bonaparte left a garrison; and reached Cairo on the 14th of June, twenty-six days after breaking up from before Acre, having been much harassed in their retreat by the Syrians. The loss sustained by the French army during the four months of the Syrian expedition is estimated at seven hundred men who died of disease, five hundred killed in the different actions, and about eighteen hundred wounded; in all two thousand nine hundred men *hors de combat*. But even this is probably below the truth.

During the absence of General Bonaparte in Syria, no method had been left unattempted in order to ruin the interest of the French in Egypt, and kindle a rebellion in that country; and to a certain extent these efforts had been successful; but the presence of Bonaparte speedily restored tranquillity. His army had no doubt suffered severely in its retrograde march from Syria; but with such zeal and activity did he direct his attention towards its organization, that in the short period of three weeks it was in a condition to resume active operations, a though, according to the accounts then current, it had been completely buried in the burning sands of the desert. After affording the Turks all the assistance in his power, Sir Sidney Smith, on the 12th of June 1799, set sail from the bay of Acre, and proceeded first to Beruta on the same coast, whence he shaped his course to Lamica road in the island of Cyprus, in order to refit his little squadron. Having effected this object, he left Cyprus for Constantinople, in order there to concert measures with the Porte for expelling the French from Egypt. But in the meanwhile an event occurred which served for the time to confirm their ascendency. When Napoleon set out on the expedition to Syria, he left Desaix, with his division, to prosecute the war against the Mamlukes; but Murad, having retired before him as far as Syene or Assouan, baffled all the attempts of the French general to bring him to action, whilst he cut off detached parties, hung on the flanks and rear of the invaders, and intercepted their supplies. Accordingly, on his return from Syria, Napoleon, having re-established the shattered discipline of his troops, was preparing to march against Murad, who had ventured down into the province of Fayoum, when he found himself suddenly called upon to confront another and apparently more formidable enemy.

On the 14th of July, the general-in-chief received intelligence from Alexandria that a Turkish fleet of from a hundred and twenty to a hundred and fifty sail had come to anchor in the bay of Aboukir, landed a body of troops on the shore of the peninsula, and carried the fort of Aboukir by assault. He accordingly issued directions to his officers to move towards the point threatened; and the first rendezvous of the army was appointed at Rhamanieh, on the left bank of the Nile. The advanced guard under Murat took the route to Ghizeh, followed by the divisions of Lannes and of Bon; Kléber's division marched from Damietta; Regnier, who was in Sharkieh, received orders to march on Rhamanieh, after leaving a column of six hundred men to protect his communication; and the whole, including Menou's moveable column, together with the park of artillery and the staff, moved on to Rhamanieh, which Napoleon reached on the 20th of July. The general-in-chief was in hopes that he would be able to destroy the army which had landed at Aboukir before that of Syria, raised during the two months which had elapsed since he quitted that country, could arrive before Cairo; and these hopes were completely realized. After the French army broke up from its position at the village of Birket, which had been fixed as the centre of its movements, it assembled near the Wells, between Alexandria and Aboukir; and Bonaparte fixed his head-quarters at the former place. The Turkish army amounted to about eighteen thousand men, and was receiving daily reinforcements; but it had no cavalry. It had taken up a position on the peninsula of Aboukir, which it was now engaged in fortifying by means of two lines of entrenchments; one joining the redoubt in front of the village to the sea, and the other three quarters of a league in advance, having the right supported by a sand-hill commanding Lake Maadieh, and the left extending to the Mediterranean, so that it could march thence either on Alexandria or Rosetta. Concluding, from the nature of these fortifications, that the Turkish army wished to make this point its centre of operations, Napoleon made his dispositions accordingly. Having set out from Alexandria on the 24th, he proceeded to the Wells, about half way across the isthmus, where he encamped, and was there joined by all the troops which were at Birket. By the mistake of a company of sappers the Turks now learned, for the first time, that the general-in-chief and the French army were opposite them, and accordingly passed the whole night in making their final dispositions to receive the attack which they knew to be inevitable. The plan of the French general was to attack instantly, and either to gain possession of the whole peninsula, or at least to oblige the first line of the enemy to fall back on the second, by which means the French would be enabled to occupy the position of the first line, and to overwhelm the Turkish army, thus hemmed in, with bombs, howitzer-shells, and balls, of which there were immense supplies in Alexandria. Accordingly, Lannes, with eighteen hundred men, moved against the left of the enemy; Destaing, with a like number of troops, prepared to attack the right; and Murat, with all the cavalry and a light battery, divided into three corps, remained opposite the centre, ready to act according to circumstances. The skirmishers on both wings soon engaged with those of the enemy, and in a short time the battle became general. The Turks, however, maintained the combat with success, until Murat, having penetrated their centre at the head of his cavalry, wheeled his left to the rear of their right, and his right to the rear of their left, thus cutting off the communication between the first and second lines. The first line now fell into complete disorder, and rushed tumultuously towards the second, consisting of about nine thousand men; but being encountered by the French cavalry in the midst of the plain, their right was driven into the sea, and their left into Lake Maadieh, whilst the columns of Lannes and Destaing advanced at the charge and vigorously pursued them. An unprecedented spectacle was now exhibited. To escape from the French cavalry and infantry, the fugitives threw themselves into the water, and were almost all drowned, scarcely a hundred men out of ten thousand having succeeded in getting on board the vessels. The French now advanced to the attack of the second line, and Lannes forced the entrenchments at the point of their junction with the lake, at the same time making a lodgment in the first houses of the village of Aboukir. Mustapha Pasha, who was in the redoubt, then made a sortie, debouching with a strong body, and separating the French right from the left, which he took in flank at the same time that he placed himself in rear of the right; but his attack was checked by the general-in-chief, who forced him to give ground, and enabled Lannes to continue his movement. Finding themselves thus cut off, the Turks instantly fell into the most frightful disorder, and, as General Destaing was advancing at the charge against the intrenchments on the right, they tried to regain the fort; but, like the first line, the second was now encountered by Murat's cavalry, and had it not been for the village, which afforded shelter to those who had time to reach it, not a man of them would have escaped. As it was, three or four thousand Turks were driven into the sea, and Mustapha, with his whole staff, and from twelve to fifteen hundred men were surrounded and made prisoners. The French loss amounted to near three hundred men. Sir Sidney Smith was a spectator of this dreadful overthrow, having arrived in Aboukir, and landed during the action: he narrowly escaped being taken, and reached his ship with great difficulty.[1]

The Turks had still left three or four thousand men, who occupied the fort, and barricaded themselves in the village. But as it was not thought possible to force the enemy in the houses which he occupied without great loss, protected as he was by the fort, a position was taken, and the most advantageous points were fixed on for placing heavy cannon, to raze the enemy's defences without risk of further loss. General Menou conducted the siege with vigour and address, and after bombarding the fort for eight days, until it exhibited nothing but a heap of ruins, the son of the pasha and two thousand men laid down their arms, and became prisoners of war. In the fort the French found eighteen hundred men killed, and three hundred wounded.

On the 26th, Napoleon returned to Alexandria, where he first learned, as is said, from some English newspapers, the reverses experienced by the French, particularly in Italy and on the Rhine; as also the violent commotions which were agitating the interior of France. This determined him to abandon the East and return to Europe, in order to be in readiness to profit by events, and to take advantage of that fortune in which he already placed unbounded confidence. Berthier alone was entrusted with the secret intentions of the general-in-chief, and proved himself worthy of this confidence. Meanwhile, Admiral Ganthéaume was ordered to get ready two frigates with the utmost expedition, but without being informed as to their destination; and Napoleon brought with him Generals Lannes, Marmont, Murat, and Andréossi, together with Monge and Berthollet of the Institute; whilst Bessières and his guides received sealed notes, which were not to be opened till a certain day and a certain hour, at a particular point of the sea-shore, and which were found to contain orders for immediate embarkation. Another sealed packet, which was to be opened on the day after the frigates had sailed, contained the nomination of General Kléber to the chief command, and of Desaix to that of Upper Egypt.[2]

The departure of General Bonaparte appears to have revived the courage of Murad Bey, and inspired him with a determination to attempt something against the French.

---

[1] In describing "cette glorieuse journée," a writer in the *Dictionaire Historique*, says, "La déroute est complète; l'ennemi, dans le plus grand désordre, et frappé de terreur, trouve partout les baïonnettes et la mort. Dix mille hommes se précipitent dans la mer; ils y sont fusillés et mitraillés." (Vol. i. p. 10.)

[2] Napoleon has been severely censured for his desertion, as it is called, of his companions in arms. But his own answer appears to be quite decisive. "Napoleon," says he, "returned to France, 1*st*, Because his instructions authorized him to do so; he had carte-blanche in all respects: 2*dly*, Because his presence was necessary to the republic: 3*dly*, Because the army of the East, which was victorious and numerous, could not, for a long time, have any enemy to contend with; and because the first object of the expedition was accomplished: the second could not be attained so long as the frontiers of the republic should be menaced, and anarchy should prevail in the interior." (*Memoirs*, vol. ii. part 2, p. 212.) If Kléber had not been assassinated, and if Menou, than whom a less military man never commanded, had not been at the head of the French army, Napoleon would probably have been spared the reproach of deserting this army from a foresight of coming misfortunes. It is evident, indeed, that when he left Egypt in August 1799, he thought that country secured to France, and hoped one day to be able to realize the second object of the expedition. Kléber had under his command 28,000 men, of whom 25,000 were in a condition to take the field; and there can be little doubt, we think, that, at the head of such a force, *he* would have been able to maintain himself in the country.

But his enterprise proved unfortunate. Having descended the Nile as far as El-Ganayur, he was repulsed by a division of the army of Upper Egypt, under the command of General Morand; and being overtaken in his flight, his camp was surprised at Samahout, a great number of Mamlukes were entirely cut off, two hundred camels with spoils, a hundred horses, and a prodigious quantity of military implements, fell into the hands of the republicans; and it was with the utmost difficulty that the bey himself effected his escape. Thus signally defeated, Murad wandered through the inhospitable deserts of Upper Egypt in search of an asylum and the means of subsistence. But as he had proved an indefatigable enemy to the French, and was dreaded even in his misfortunes, Desaix resolved if possible to exterminate him; and for this purpose he caused two columns of infantry mounted on dromedaries to be immediately organised, the one commanded by himself in person, and the other by Adjutant-general Boyer. On the 19th of October, after a forced march of three days, these moveable columns overtook Murad in the desert of Sediman, and a combat immediately ensued. The Mamlukes, animated with the hopes of gaining possession of the dromedaries, fought with determined valour. But their attack was met with such vigour on the part of the French, that they were soon put to flight, and pursued back to the deserts by their indefatigable antagonists.

On the 24th of September, a Turkish fleet of eighteen vessels came to anchor before Damietta, and was so rapidly increased by constant reinforcements, that towards the end of the subsequent month it amounted to fifty-three vessels. This fleet was commanded by Sir Sidney Smith, whose flag was hoisted on board of the Tigre. On the 1st of November, four thousand Turks having effected a landing, were attacked by General Verdier at the head of only a thousand men, and, notwithstanding their great superiority of numbers, were defeated with a loss of three hundred men killed, eight hundred prisoners, including Ismael Bey, the second in command, thirty-two stand of colours, and five pieces of cannon. After a number of other affairs, which were fought with various success, the French seemed willing to evacuate Egypt upon certain conditions; and in December, General Kléber, upon whom the chief command had devolved, made proposals of peace to the grand vizir. These were communicated to Sir Sidney Smith, and it was at length arranged that a conference should be held on board the Tigre, then at anchor in the bay of Acre. Kléber appointed as commissioners on the part of the French, General Desaix and M. Poussielgue, who, towards the end of December, embarked for the capital of Syria; but a gale of wind, which drove the Tigre to sea, prevented the ship, for eighteen days, from returning to the bay. The commissioners then made and received certain propositions in writing, after which they were landed; and on the 24th of January 1800, these terms, having been reduced into form, were mutually signed at El-Arisch. By this convention[1] it was stipulated that the French army, with all its stores, artillery, and baggage, along with the ships of war and transports at Alexandria, should be permitted to return to France unmolested by the allied powers. But Vice-admiral Lord Keith, who commanded in chief in the Mediterranean, refused to ratify the treaty entered into at El-Arisch; and the French, considering themselves as deceived and insulted, indignantly recommenced hostilities, and gained several advantages over the Turks. The British government, however, becoming sensible of the advantage of clearing Egypt of the enemy without bloodshed, at length agreed to accede to the convention. But it was now too late. Kléber, indignant at the deception practised on him, had turned upon the Turks at Heliopolis, routed the army of the grand vizir with great slaughter, and driven the remains of it into the desert of Syria; and Menou, who, on Kléber's assassination,[2] had succeeded to the chief command, encouraged by the hopes of receiving fresh supplies and reinforcements from Europe, and considering that the French had made themselves masters of all the strong posts throughout Egypt, resolved to retain possession of the country at every hazard, and to defend his positions against any force which might be brought to oppose him. Accordingly, after driving the wrecks of the grand vizir's army from Gaza, where they had endeavoured to rally, and also threatening Syria with another inroad, he strongly fortified Alexandria, Damietta, and Rosetta, and not only completed the lines which had been commenced at Aboukir, but made several important additions, and put every place into such a state of defence as enabled it to bid defiance to any attack upon the part of the Turks.

In the mean time Great Britain was not idle. Having organized an army destined to invade Egypt and compel the French to evacuate that country, the command of it was entrusted to Sir Ralph Abercromby, who had distinguished himself both in the West Indies and in Holland. In the beginning of March 1801 he appeared off Aboukir Bay; but the weather having proved unfavourable, the disembarkation of the troops did not commence until the morning of the 8th. Meanwhile the French having marched from Alexandria, took up a position on the heights of Aboukir, to oppose the landing of the British forces; but, by the admirable arrangements of the navy, the disembarkation was effected in spite of all opposition, and the enemy were dislodged from the sand-hills which commanded the landing place, by the troops gallantly charging up the heights the instant they were formed on the beach. The action lasted two hours; but the French having only about four thousand men to oppose nearly three times that number, were at length obliged to sound a retreat. The loss of the French on this occasion was estimated at three thousand, and that of the British at fifteen hundred men, in killed, wounded, and prisoners. A portion of the army then moved forward, and on the 13th a sharp encounter took place, in which, owing partly to ignorance of the country and the delusion created by the mirage, several British regiments, including the 92d, suffered severely. But the battle which in a great measure decided the fate of Egypt took place on the 21st of March, about four miles from Alexandria. It began at daybreak, by a false attack on the left of the British; but the efforts of the French were chiefly directed against the right of their opponents, which they attempted to turn, and at one time had nearly succeeded. Being at length repulsed, however, they next attacked the centre, though with less vivacity, and were here also defeated. None of these attacks was made with sufficient continuity, or in a manner which deserved success, being rather partial onsets than vigorous, decided, and sustained efforts directed to the accomplishment of a definite object. Having failed in his ill-directed attempts to penetrate the British line, Menou at length retired upon Alexandria, leaving the field of battle in possession of his adversaries. About two hundred prisoners fell into the hands of the British; but as the latter were much inferior in cavalry to the enemy, whose retreat was also covered by cannon planted on the opposite heights, they were unable to pursue their advantage. The loss of the British was very considerable, but the most irreparable part of it consisted in that of the commander-in-chief, who was mortally wounded, and died on the 28th. He was succeeded by General Hutchinson, the second in command, to whom was committed the completion of the conquest of Egypt.

---

[1] Napoleon affirms that "intriguing persons had made Kléber sign" the "capitulation" of El-Arisch (*Memoirs*, vol. ii. part 2, p. 214); and it is certain that the French officers generally were sick of the war in the East, and desirous to return to Europe. But as to the assertion that Kléber negociated with the allies merely to gain time, and that he never intended to accede to the convention; an assertion which has been reiterated in a great number of works, from the Travels of Dr Clarke to the Memoirs of Bourrienne; it betrays an entire ignorance of facts. Kléber had actually signed the capitulation, and was preparing to execute it on the part of the French, when a notice arrived from Sir Sidney Smith that hostilities were to be continued in consequence of Lord Keith's rejection of the treaty. This prompt intimation, alike honourable to Sir Sidney and worthy of the British character, was duly appreciated by the French, when it became known to them that the Turks, apprised of the admiral's refusal to ratify, intended to take advantage of Kléber's ignorance, and to attack him whilst resting on his arms, in reliance on the faith of the treaty. The low morality of the Osmanlees led them to regard the meditated act of treachery as perfectly allowable; and accordingly they never forgave Sir Sidney for his generous integrity, considering him as one who had sacrificed their interests, if not betrayed their cause.

[2] This gallant and experienced officer was treacherously assassinated by a janizary, whilst presenting a memorial for his perusal. Suspicion at first fell on Menou, who, as a difference subsisted between him and Kléber, was supposed to have hired the assassin; but the dying assertions of the murderer clearly established the injustice of this suspicion. If not impelled by mere fanaticism, the assassin was most probably hired by the grand vizir; and the abominable treachery which the Turks are known to have contemplated, after Lord Keith's refusal to execute the convention of El-Arisch, serves to countenance this supposition. The assassin himself was impaled alive, his right hand was burned off, and his body was left to be devoured by birds of prey. Three sheikhs who were privy to his designs, but did not divulge them, were also beheaded.

The new commander-in-chief having invested Alexandria, at length proceeded against the French, whom he attacked on the 19th of May, near Rhamanieh, and forced to retire towards Cairo. He had under his command four thousand British troops, with an equal number of Turks under the capitan pasha. He then directed his march towards Cairo, from which the army of the grand vizir was at this time distant only four leagues, and where the main strength of the French army had now assembled. With nine thousand chosen troops, the grand vizir, assisted by some British officers then in his camp, gained an advantage over a body of from four to five thousand French; Damietta soon fell into the hands of the allies; and the successor of Murad Bey, who had died of plague, having declared in favour of the British, joined General Hutchinson with fifteen hundred cavalry. Belliard, who commanded in Cairo, satisfied that without reinforcements from Europe the war could not be prosecuted with any prospect of success, now proposed terms of capitulation; and, on the 27th of June, a convention was accordingly concluded, by which the French agreed to evacuate Cairo, on condition of being sent to France, with their arms, cannon, baggage, and colours, without being made prisoners of war. But Alexandria, which was strictly blockaded by General Coote, still held out; and Menou had somewhat hastily expressed a determination to bury himself in the ruins rather then surrender. Such vows, however, being generally made with a tacit mental reservation, are seldom observed with literal fidelity. A regular bombardment was commenced by the ships in the harbour, and the batteries on land;[1] the defences began to give way; a practicable breach was made; and the besiegers were about to make preparations for the assault, when Menou, who evidently waited for the moment when he might yield without dishonour, signified his readiness to listen to terms. A convention was accordingly entered into, and on the 2d of September the garrison capitulated on nearly the same conditions which had been granted to General Belliard at Cairo.

It is not a little remarkable in itself, and may serve to illustrate the wisdom with which the affairs of this country were then managed, that after the campaign of 1801, which cost Britain several millions sterling, ten thousand of her best soldiers, and the commander-in-chief of her army, General Belliard at Cairo, and General Menou at Alexandria, obtained almost the same capitulation which Kléber, twenty months before (24th January 1800), had signed at El-Arisch; in other words, all these sacrifices had been made to bring about the same result which, but for the inexplicable opposition of Lord Keith, Sir Sidney Smith would have effected without the expenditure of a guinea or the loss of a single life. If ever glory was barren, therefore, that which the British had gathered in the expulsion of the French deserves such a qualifying epithet. But, however this may be, Egypt, after having been for more than two years the theatre of almost incessant conflicts, was once more reduced under the government of Turkey, and obliged to acknowledge the authority of the Ottoman Porte; a result, we may add, which proved as evanescent as all the other objects of British policy regarding that country.

It would indeed be difficult to give any satisfactory account of the views which Great Britain at this period entertained regarding Egypt. Her policy was too vacillating to be reconciled with any fixed principle of action.

---

[1] When General Hutchinson marched for Cairo, leaving General Coote to blockade Alexandria, the latter officer, wishing to strengthen his position, and shorten the line of the blockade, had recourse to an expedient which wisdom and humanity must alike condemn. In the pocket of General Roiz, who had been killed in the action of the 21st of March, there was found a letter written by Menou, expressing an apprehension that the British would cut the embankment along which was carried the canal of Alexandria, and thereby admit the waters of the sea into Lake Mareotis. From this moment the project unhappily suggested in this letter became a favourite object with the army. By securing the left and part of the front, the duty would be lessened, the French cut off from the interior, and a new scene of operations opened: these were the military advantages which the execution of this project would ensure, and the army thought of nothing else. But there were nevertheless grave objections to the measure. The mischief it might do was incalculable; the Arabs could give no information where the sea, if once let in, could be checked; and the ruin of Alexandria might probably be the consequence. Besides, it was argued that the inundation, whilst it covered the British left, would also secure the French front, except from a new landing. But every consideration yielded to the supposed urgency of the service, which superseded all remoter considerations; and the measure was determined on. To comprehend the precise nature of the operation, however, it is necessary to attend to the natural formation of the country. To the south and westward of Alexandria extends a valley, running in the latter direction upwards of forty miles, and forming the bed of the ancient Lake Mareotis. Of this hollow space a large portion was under the level of the sea, which, therefore, was only prevented flowing into it by the dike or embankment along which runs part of the canal from the Nile to Alexandria. General Coote accordingly directed four cuts of six yards in width, and ten yards asunder, to be made in this embankment; and his orders were executed with the zeal and alacrity generally displayed in the work of authorized destruction. When the fascines which protected the workmen were removed, the water rushed in with a fall of nearly seven feet, and with such force that the portions of the dike intervening between the cuts were all washed away; yet although the whole breach widened to the extent of a hundred yards, it was nearly a month before the valley filled and the water found its level. Thus a work which formed the pride as it had ever been the peculiar care of Egypt, which it had required the labour of ages to construct and consolidate, and which all former invaders, however barbarous, had spared, was in a few hours destroyed by the ruthless hands of British soldiers. (Stewart's *Military Service of the Highland Regiments*, vol. i. p. 482, 2d edition.)

At first she seemed disposed to establish her power in that country; then she renounced all idea of such an establishment; her ambassador at Constantinople applauded the destruction of the Mamlukes; then hopes were held out by her to the Beys, and whilst she neglected to apprise them of the danger which impended over them, she sought to save them when their ruin was inevitable. But the Beys merited different treatment. They had resolutely opposed the French from the first moment of the invasion, and by the heavy losses which they had sustained in this unequal contest, their power was so far reduced as to leave them in some measure at the mercy of the Turks. In assisting to expel the French from Egypt they had thoughtlessly sacrificed their own means of self-defence. But this circumstance gave them an undoubted claim to the protection of the British, whose allies they had been in the contest; and their claim was distinctly recognized by General Hutchinson, who interposed in their behalf, and exerted himself to procure for them the most favourable terms. The Capitan Pasha, however, had vowed their destruction, and, as usual with Turks, he set about the accomplishment of his object by means of dissimulation and treachery.

Pretending to enter into the views of General Hutchinson, who insisted that their rights and dignities should be restored to the Mamlukes, on condition of their paying the usual tribute to the sultan, Hassan reinstated Ibrahim Bey, who was now at the head of their affairs (Murad having fallen a victim to the plague), in his former office of Sheikh-el-Belled; he also lavished favours and caresses on the other chiefs, and sought by every means to gratify their pride, and, above all, to allay their suspicions. In this he was but too successful. Hassan enacted his part so well, and seemed so sincere in his professions, that these rough soldiers, forgetting all the lessons of former experience, suffered themselves to be led as it were blindfold into the snare which had been so artfully prepared for them. Accordingly, having so far attained his object, the Capitan Pasha invited the principal Beys of the house of Murad, including Osman Bey Tambourgi, Osman Bey Bardissi, Murad Bey Soghayr, and several others, to visit his camp at Aboukir. After some hesitation, they resolved to accept of Hassan's proffered hospitality, and repaired to Aboukir, where they were received with every mark of honour and distinction. Their tents were placed in the demilune formed by the encampment of the troops, and pleasure and amusement were the order of the day. The time passed in paying visits of ceremony, and in military promenades, and already a month had elapsed without their receiving from the Capitan Pasha so much as even a hint of his intentions respecting them, or of the object of his invitation. This long silence alarmed them, and they expressed their fears to General Hutchinson; but that officer, never suspecting the atrocity which Hassan was meditating, assured them of the friendly dispositions of the pasha, and the good intentions of the Porte, towards them. This assurance, however, was not sufficient to quiet their fears; their distrust increased every instant; and several had resolved to quit the camp without taking leave of the pasha, and to return to Cairo.

But the crisis was at hand. Whilst matters were in this state, the Capitan Pasha and the Beys were invited to an entertainment to be given at Alexandria on the occasion of General Hutchinson's resigning the command to Lord Cavan, prior to his departure from Egypt. On the morning of the day appointed for the festival the pasha had the Beys to breakfast in his tent; and, after the repast, the whole party embarked on board some boats which had been provided for the occasion. The pasha went in his own cutter with the Beys and some of their Mamlukes, whilst the other boats were appropriated to the officers of his suite. When they had proceeded to a short distance, the Capitan Pasha perceived a light skiff rapidly approaching: "There," said he to the Beys, "are doubtless dispatches for me from Constantinople." Anon the skiff came alongside, and a packet was handed to the pasha, which he immediately broke open, and, on pretence of reading his dispatches more at leisure, stepped on board the small boat, which immediately dropped astern. Meanwhile the other boats proceeded on their course, the skiff following at a great distance; when, on entering the lake of Aboukir, the Beys suddenly discovered before them three large sloops filled with soldiers armed and ready for action. They now saw that they had been betrayed, and accordingly prepared to defend themselves. Mohammed Bey Manfoukh drew his sabre, and the rest followed his example; the sloops opened their fire, and these brave men fought like lions against the Turkish soldiers; but in this unequal contest valour proved unavailing against numbers; and discharges of artillery and musketry hurled destruction amongst the boats. Osman Bey Tambourgi, Murad Bey, Osman Bey el Achkar, Ibrahim Kiaya Sennary, and several Mamlukes, were killed; whilst Osman Bey Bardissi and Ibrahim Bey Hussein were severely wounded. Those who escaped the massacre were taken prisoners, and carried on board the ship of the Turkish vice-admiral, where they were compelled to swear on the Koran that they would not demand to be given up to the British, and would remain in the hands of the Turks.

When the news of this catastrophe reached Alexandria, General Hutchinson dispatched General Stuart to the Capitan Pasha to reproach him with his abominable treachery; and at the same time the British army left its camp, and formed in order of battle opposite the Turks. The resentment of the troops knew no bounds, and they burned to avenge so sanguinary a violation of the laws of hospitality. But the Capitan Pasha, alarmed at this demonstration, lost no time in complying with the demands of the British general; the prisoners and the wounded were landed and conveyed to Alexandria; and to those who had fallen the British army rendered the honours of military sepulture.[1] The pasha then sent Isâk Bey, his interpreter and confidant, to endeavour to pacify the British general, who had been greatly exasperated at the treachery of the Turk, and who, in a conversation which ensued with the envoy, described the conduct of his master in the only language fitted to characterize its atrocity.

As soon as the objects of his expedition had been attained, Hassan, not chusing to winter in the open road of Aboukir, made the necessary preparations for embarking the troops under his command, and having broken up his camp, set sail for Constantinople. After his departure, Mohammed Kusruf, his favourite slave, who had been appointed pasha of Cairo, repaired to the capital in order to assume the reins of government. A Georgian by birth, this minion of fortune had owed his elevation to his plausible manners and artful flatteries; but, from want of prudence and knowledge of mankind, he soon showed himself unequal to the station to which he had been raised, and his inexperience proved the cause of his subsequent misfortunes. As soon as he had taken possession of his pashalik, Kusruf commenced military operations against the Mamlukes, who, having rallied under Osman Bey Bardissi, had retired into Upper Egypt, their usual asylum, where they set the pasha at defiance. Having failed to induce them to return and fix their residence in the capital, the latter dispatched into the Saïd a corps of six thousand Albanians under the command of Taher, their chief, assisted by the celebrated Mehemmed Ali, then beginning to rise into power, with orders to seize Elfi Bey, and to dislodge the Mamlukes. But this expedition proved abortive. Taher returned without effecting any thing of consequence, and all attempts at negociation proved equally unavailing. Emboldened by this failure, the Mamlukes descended into the province of Fayoum, which they plundered, and extending their ravages into the provinces of Minyeh and Benisouef, they at the same time threatened the capital itself. In these circumstances, Yussuf Bey, kiaya of Kursuf, having assembled a considerable force, and been joined by Taher with his Albanians, received orders to proceed against the Mamlukes, and directed his march upon Damanhour, where part of them had encamped under the command of Osman Bey Bardissi. A battle ensued in the neighbourhood of this place; the Mamlukes, with their usual impetuosity, charged the left flank of the Turks, which had been left uncovered; the Turkish infantry, broken by the shock, fell into irretrievable disorder, and the sabres of the Mamlukes soon completed their overthrow. The first charge decided the victory. The Turks were miserably defeated, with the loss of about five thousand men killed and wounded; whilst the success of the Beys cost them only between sixty and seventy men. But the latter neglected to profit by their victory, and instead of pushing directly for the capital, which was in no condition to oppose them, they allowed the viceroy time to rally the fugitives, and to place Cairo in a tolerable state of defence.

[1] Mengin, *Histoire de l'Egypte sous le Gouvernement de Mohammed-Aly*, vol. i. pp. 13–16. *Zeitschrift für Kunst und Gesch. des Krieg.* January and February 1831. *Abrégé de l'Histoire des Mamlouks, Bulletin des Sciences Militaires*, vol. x. p. 219.

The troops of Taher Pasha and of Mehemmed Ali, by reason of their distance from the scene of action, had not taken part in the battle of Damanhour, which in fact had been fought by the Turks with only a part of their force, and before the Albanians could join. This, however, did not prevent Yussuf, who had escaped the sabres of the Mamlukes, from attributing the loss of the battle to the cowardice or disaffection of Mehemmed Ali, who, as he alleged, had treacherously kept back his troops; and although the accusation appears to have been groundless, it was not on that account disregarded by Kusruf, who had already seen cause to dread the commanding talents and aspiring character of this remarkable person, and who, accordingly, resolved to avail himself of the pretext thus offered in order to effect his destruction. An attempt was accordingly made to bring him to trial for neglect of duty; but ere this could be effected, there broke out a revolt, which soon became a revolution, and which in its ulterior consequences has exercised the most powerful influence upon the destinies of Egypt. Before proceeding, however, to notice the circumstances attending this memorable revolt, headed by Taher Pasha, we shall interrupt the progress of the narrative for a little, and, in order that the connection of events may be preserved, take a retrospective survey of the origin, early fortunes, and gradual rise to distinction, of the remarkable individual who has so deeply impressed the great lineaments of his character upon the history of Egypt.

Mehemmed Ali, viceroy of Egypt, is a native of Cavalla, an obscure village in Rumelia, a district of Albania. Having lost his father in early life, he entered the service of the governor of his native town, under whom he appears to have received that species of training which qualifies a man to rise in such a country as Turkey, where energy, intrepidity, and expertness in the use of arms, are considered as the most valuable accomplishments. He commenced his career as a subordinate tax-gatherer, an office to which his activity had recommended him; and, in the discharge of his duty, he soon gave proofs of that decision of character and of those resources of mind for which he afterwards became so distinguished, exacting the money he was ordered to raise with most impartial rigour, and not sparing the blood nor even the lives of the unhappy peasantry over whom his fiscal jurisdiction extended, when they attempted, as sometimes happened, to resist his demands. It has been said that the youth is father to the man; and, upon the same principle, the Rumeliot tax-gatherer may be described as father to the future pasha and viceroy. On one occasion, the inhabitants of a village having refused payment of the tax imposed on them, at first threatened, then resisted, and at last broke out into open revolt. Alarmed at this unusual boldness, and dreading the effect of the example, the governor sent for Mehemmed, who at once undertook to reduce them to obedience. Having assembled a few men, whom he hastily armed, the young collector accordingly proceeded at their head to the refractory village, where, having announced that he was charged with a secret mission, he entered a mosque, and summoned the principal inhabitants to meet him in the house of prayer. Not suspecting any violence, the heads of the village obeyed his summons; but no sooner had they come within the walls than he ordered them to be bound hand and foot, and immediately set off with his captives for Cavalla, pursued by the villagers, whom, however, he overawed by threatening, in case they made any attack, to put their friends to instant death. This vigorous proceeding, evincing a characteristic union of conduct and firmness, procured for him the rank of Bulukbashi, and a rich wife, a relative of his patron the governor. He next became a dealer in tobacco and other merchandise, a business which he is understood to have followed with considerable success; and as mercantile pursuits are not held in Turkey to be incompatible with military duties, Mehemmed, ever careful not to neglect the latter, gradually worked his way up to that degree of consideration which gained him the command of the contingent of troops furnished by his native district to the army with which Turkey was then preparing to defend Egypt against the French. In 1798, Bimbashi or Major Mehemmed Ali reached Egypt with his contingent of three hundred Albanians, and from the day of his landing in that country his rise was uniform and constant. This command, which opened the field of future greatness to Ali, has been attributed by some to the fact of his having married a rich wife, just as the fortunes of Bonaparte have, by a similar class of reasoners, been ascribed to the accident which, in the same year, led to his union with the widow of General Beauharnois.

Not long after his arrival in Egypt, the Rumeliot tax-gatherer and tobacconist, by his gallant conduct on the field of battle, attracted the particular notice of the pasha, who recommended him to Kusruf, the governor of Cairo. This was his first step towards advancement in that country where he was destined ere long to establish an undisputed supremacy of power. After the massacre of the Mamlukes at Aboukir, he became a general of division in the army of Yussuf Bey, and was marching at the head of his division towards Damanhour, when the precipitation of Yussuf brought on the battle with the insurgent Mamluke chiefs, which terminated so fatally for the Turks. Yussuf, as we have already seen, attributed his miserable defeat to the alleged misconduct or disaffection of Mehemmed, whom he accused of having purposely delayed the advance of his division; and the charge, whether groundless or not, was entertained by Kusruf, now pasha of Egypt, who accordingly resolved to expel the young Albanian general from that country. But he little knew the character of the person with whom he had to deal. The pay of the troops being considerably in arrear, they applied for redress to the pasha, who referred them to the defterdar, or minister of finance ; but the latter being in no condition to satisfy their demands, told them to go to Mehemmed Ali, who, in his turn, assured them that he had not received a piastre for the liquidation of their claims, and at the same time encouraged them to persevere in their demand for payment. Meanwhile the viceroy sent orders to Mehemmed to appear before him in the night ; but the latter, not unacquainted with the object of such private interviews, returned an answer stating that he would appear on broad day in the midst of his troops. The danger of the viceroy now became imminent. The soldiers demanded their arrears in an audacious tone, accompanied with menaces, which Kusruf, reckoning on his means of repression, had the imprudence to despise ; a revolt immediately broke out ; the artillery opened on the mutineers, who replied by volleys of musketry directed against the palace of the viceroy ; and a fierce conflict ensued. The soldiers of Ali, who had been cantoned in the environs of the capital, now joined the insurgents, and the battle became general. At this moment, Taher Pasha, chief of the Albanians, went to present himself before the viceroy, and to offer to become mediator between him and the exasperated troops. But Kusruf refused to see him, and sent him orders to return to his residence, without concerning himself about what was passing. Taher, however, chose to follow a different course. Repulsed by the viceroy, he now openly took part with the mutineers ; and having, partly by force and partly by stratagem, obtained possession of the citadel, he attacked the palace, whence the viceroy was soon forced to fly with his wife and one or two attendants to Mansoura. In short, the revolt speedily became a revolution, and the vice-regal power passed from the hands of Kusruf to those of Taher Pasha.

But the power which the Albanian chief had acquired by mutiny was soon lost by misconduct. Taher governed only twenty-two days, during which brief space he committed all sorts of injustice and cruelty, and in particular caused two Coptic intendants and a merchant of Damascus to be decapitated. His career was cut short by two Turkish bimbashis, who anticipated the wishes of the Porte, which, on receiving intelligence of what had occurred in Egypt, dispatched a couple of capidgis-bashis for the head of Taher. The Mamlukes, seconded by Mehemmed Ali, now entered Cairo, and having formed an alliance with the Albanians, the government reverted into the hands of their chiefs, Ibrahim Bey and Osman Bey Bardissi, in conjunction with Mehemmed. The new allies then marched an army against Kusruf Pasha ; besieged and took Damietta, into which the viceroy had thrown himself with his adherents ; and having made the latter prisoner, conducted him back to Cairo. Meanwhile the Porte observing Egypt about to slip a second time through its fingers, lost no time in dispatching a new pasha, Ali Gezaïrli, to assume the direction of affairs ; but as soon as the intelligence of his arrival reached the confederate chiefs, they quitted Damietta, marched against the intruder, and soon forced him to take refuge within the walls of Alexandria. Whilst matters were in this state, discord arose between the Mamlukes and Albanians. The latter demanded their pay, which had fallen into arrear, from Osman Bey Bardissi, and not receiving any satisfactory answer, they quitted the camp at Damanhour, and returned to Cairo under the conduct of Mehemmed Ali. Osman Bey Bardissi made the same movement with his Mamlukes, and returned to Cairo, where he resumed the direction of affairs. Profiting by this disunion, Ali Gezaïrli summoned the rebels to submit to his authority ; and, to his great surprise, the summons was obeyed. Full of hope, and conceiving he had now the ball at his feet, Ali set out for Cairo at the head of a considerable force, instead of an escort merely, as had been agreed on. But the Mamlukes and Albanians, apprised of his design, took up a position at Chalakan, near the Nile, where they awaited the arrival of the pasha. Ali here attempted to negociate, and even tried to draw over to his side some of the commanders of the confederate insurgents ; but these men, aware that they had gone too far to recede, treated his advances with disdain ; and the Mamlukes having charged with their usual impetuosity, overthrew the pasha's force in an instant, and put to death Ali himself, whom they overtook in his flight from the field of battle.

As the undisputed ascendency of the Mamlukes might in the end have proved fatal to designs which Mehemmed Ali was now cherishing, the wily Albanian, who knew that he was an object of dread and suspicion both to Turks and Mamlukes, contrived to embroil Bardissi, the Hotspur of the Beys, with some of his associates, and to fan the flame of that discord which he had artfully kindled. These impetuous and headstrong men fell into the snare which had been laid for them ; they went to war amongst themselves, and sought to exterminate one another, whilst Mehemmed took care to keep alive the disunion by which he was so soon to profit. At length, on the 12th of March 1804, he threw off the mask, attacked Bardissi and Ibrahim in their palaces, whence these brave men cleared a passage with their swords ; and recognized Kusruf, whom he took out of prison in the citadel, as pasha of Egypt, intending, no doubt, to use the latter as an instrument for promoting his own ends. But shortly afterwards he again expelled the unfortunate viceroy, who was promptly replaced by Kurschid Pasha. Meanwhile the Beys having taken refuge in Upper Egypt, commenced war against the Turks and Albanians ; and Elfi Bey, who had been for some time in England, having by this time returned, joined his brethren in arms ; but his counsels, though they served to delay, could not avert the fate which now impended over the Mamlukes. An order issued by the Porte for the return of the Albanians to their own country, brought on the crisis which had been long prepared. Mehemmed, whose designs were in a great measure matured, disobeyed the mandate, upon the pretext that his services were still necessary to repress the audacity and insubordination of the Mamlukes. The people of Cairo rose, and the sheikhs and ulemas having proclaimed Mehemmed Ali their pasha, demanded his confirmation of the Porte, which was granted. The Mamlukes were now summoned to submit to the new governor ; and as they hesitated or refused, a snare was laid for them which proved fatal to many of their numbers. Some sheikhs and Albanian captains with whom the governor maintained a secret understanding, having opened a communication with the Mamluke chiefs, promised to deliver up to them the gates of Cairo on the day of the festival of the inundation of the Nile. Accordingly, on the 18th of August 1805, a large party of Beys, who were devastating the environs of the city, penetrated into the suburbs, and, meeting with no resistance, entered Cairo itself, where all appeared equally tranquil. Nothing was heard but the sound of their martial instruments, whilst the terrified inhabitants, having shut themselves up in their houses, left the streets completely deserted. Dividing their numbers into two parties, they advanced resolutely, anticipating only a triumph ; when, all of a sudden, as soon as they had become entangled in the narrow streets of the city, a rattling fire of musketry opened upon them from the houses in which their enemies were concealed, and whence destruction showered upon their ranks. Recovering from the astonishment created by this unexpected reception, they rushed towards the gates of the city; but these having been shut immediately after their entrance, all retreat was cut off, and, with the exception of a small party who by some means contrived to make their escape, the whole perished under the musketry of an unseen enemy.

Ibrahim and Bardissi, more distrustful than their associates, had not participated in the imprudence to which so many of their number had fallen victims; and having retired into Upper Egypt, the ordinary refuge of the conquered, they defeated the troops of the pasha, and prevented the collection of the imposts; whilst Elfi, the most powerful of the Beys, reigned in Fayoum, Ghizeh, and part of Lower Egypt. Mehemmed Ali at the head of a body of troops followed their movements as far as the confines of the province of Kelouhyeh; but finding all his efforts unavailing against so active and enterprising an enemy, he returned to Cairo. The contest between Ali and the Mamlukes continued to be carried on with various fortune, though, upon the whole, to the advantage of the new governor; when the policy of England, the hatred of Kurschid towards the pasha, the influence of the gold of Elfi Bey at Constantinople, and the suspicions entertained of Mehemmed, determined the Porte to re-establish the government of the Mamlukes. Accordingly, on the 1st of July 1806, Saleh, capitan pasha, arrived at Alexandria with 3000 men of the Nizam-jedid, and ordered Mehemmed to quit Egypt for the pashalik of Salonica. A capidgi-bashi was also dispatched to Cairo to command the attendance of Ali at Alexandria, where, it was pretended, he would be formally invested with his new government. But the Rumeliot peasant was not the man to fall into so obvious a snare. Having worked his way to the eminent station which he then occupied with only five hundred men at his disposal, it was not likely that he would descend from the vantage-ground on which he stood, when surrounded by fifteen hundred resolute Albanians, ready to die in his defence. Accordingly he appealed both to the attachment of the people of Cairo, and to the affection of the Albanians; nor did he appeal in vain. The former declared loudly in his favour; and the latter, drawing their sabres, swore to conquer or die along with him. "Cairo," said he, "is to be publicly sold; whoever will give most blows of the sabre will win it, and remain master." In this coin his Albanians were quite prepared to pay down the price of the Egyptian capital upon the shortest notice. But no actual collision took place. Elfi Bey, who had promised fifteen hundred purses (L.30,000 sterling) to the grand vizir, failed to perform his engagement; dissensions broke out between him and the other Beys, who dreaded lest the protection of England should render him too powerful; and the Porte, finding itself on the eve of a war with Russia, was in no condition to engage in a contest in Egypt. Saleh accordingly received instructions to treat with the pasha upon the principle of recognizing his power; and shortly afterwards Mehemmed Ali received from the Porte his formal investiture as viceroy of Egypt. Seeing all his hopes thus frustrated, Bardissi died of grief at Monfalou, Elfi Bey soon followed him to the tomb, and his troops having disbanded, part of them entered the service of the viceroy, whose force was further increased by a battery of ten pieces of English artillery served by European cannoniers.[1]

The remains of the Mamlukes, who, as usual, had taken shelter in Upper Egypt, did not now exceed two thousand five hundred horsemen, exclusively of the Arabs their allies; and the viceroy was preparing to proceed against them, in the hope of effecting their extermination, when he received dispatches from Constantinople, announcing the commencement of hostilities between Great Britain and the Ottoman Porte, and soon afterwards found himself called to contend with a new enemy. The English ministry having resolved to send a second expedition to Egypt, a body of about five thousand men from Sicily landed near Alexandria on the 17th and 18th of March 1807, the whole being under the command of Major-General Mackenzie Fraser. The object of this ill-fated expedition was to unite with the Beys, and, by their assistance, to prevent Egypt from falling again into the hands of the French, whose ambassador at Constantinople was understood to exercise a predominating influence in the politics of the Divan. But whatever may have been the views entertained by the British government, nothing short of the most profound ignorance of the state of Egypt, the broken and dispirited condition of the Mamlukes, and the actual amount of the Turkish forces in that country, can account for their sending out such a handful of men, whom, if their calculations had been founded on the slightest knowledge, they must have been sensible they were exposing to almost certain destruction. The disembarkation of the troops was completed on the 18th, and Alexandria, after a trifling resistance, surrendered on the 20th of March. A strong detachment under Generals Wauchope and Meade was then sent to take possession of the fort and heights of Abou-Mandour, on the left bank of the Nile, above Rosetta, and afterwards to occupy Rosetta itself. The first part of this service was accomplished without opposition; and the second proved a miserable failure. Having imprudently carried his detachment into the streets of Rosetta, which are only a few feet wide, with high, flat-roofed houses on either side, pierced by windows like loop-holes, and forming a better defence to a weak enemy than a walled town, Wauchope, who had been allowed to enter without interruption, was suddenly assailed with vollies of musketry from every part, whilst the troops were unable to return a single shot with any effect, and, after an unavailing struggle, were forced to retire with the loss of nearly three hundred officers and soldiers killed and wounded. General Wauchope paid for his temerity with his life, and General Meade was wounded. This repulse disconcerted the whole enterprise, and the troops retired to Aboukir, whence they were ordered to Alexandria. But the general being still anxious, if possible, to get possession of Rosetta, he resolved to make a second and more methodical attempt to carry that town. Batteries were accordingly constructed; a line was taken up between the Nile and the gate of Alexandria; a chain of posts was established between Lake Etko and El Hamad; and when all was ready the batteries opened against the town. But their fire made little or no impression on the heavy and strong masses of building; the Turks and Albanians gave themselves no concern about the fate of the inhabitants, who were the principal sufferers; and as the houses contained scarcely any furniture, all attempts to set the town on fire proved abortive. At this period much was expected from the co-operation of the Mamlukes, who, it was thought, would descend from Upper Egypt and keep the Turks and Albanians in check; but, like all the other calculations connected with the expedition, this proceeded upon utter ignorance of the real state of affairs, and was destined to encounter speedy and severe disappointment. The enemy daily increasing in numbers and boldness, surrounded and cut off the post at El Hamad, which had been placed beyond the reach of support; the others, being similarly circumstanced, speedily shared the same fate; and no alternative remained but to retire to Alexandria, in the face of a victorious enemy, with a powerful cavalry, of which he boldly but ineffectually endeavoured to avail himself. The retreat was ably covered by Colonel, now Lieutenant-General Sir John Oswald, with the remains of the 35th and 78th regiments, whose firm front and steady fire checked the advance of the enemy, particularly at Etko, where he suffered a sharp repulse, and discontinued all further attacks. The troops remained at Alexandria until the 22d of September, when the whole embarked for Sicily. In this wretchedly-planned and worse-conducted expedition, which tarnished the glory of the British arms on the very ground where six years before they had triumphed over the veteran soldiers of France, the loss was necessarily great; and the prisoners were treated with every species of contempt and barbarity, whilst no less than four hundred and fifty heads of their comrades who had fallen were publicly exposed at Cairo.[1]

[1] *Abrégé de l'Histoire des Mamlouks. Bulletin des Sciences Milit.* tom. x. p. 222. *Zeitschrift für Kunst und Gesch. des Krieg.* 1831.

The evacuation of Egypt by the English proved a stunning blow to the Mamlukes, who, seeing all hope of regaining their former ascendency at an end, sunk into a state of extreme discouragement, and sought to forget their misfortunes by abandoning themselves to miserable and degrading pleasures. Their military ardour seemed in a great measure quenched; they had no longer any success against their enemies, yet their pride prevented them from making a tender of submission. They felt that resistance was hopeless, yet they shrunk from any acknowledgment of the weakness of which they were but too conscious. Matters were in this state when Mehemmed, moved only by considerations of policy, resolved upon their final destruction. Menaced at once by the Bedouins and the Mamlukes, he could not advance a step in any direction without danger. His people, incessantly pillaged and ransomed, were ready to break out into open revolt; whilst, to add to his embarrassments, the Porte, seconded by all true Moslemins, pressed him to march against the Wahabis, who had seized upon the holy cities of Mecca and Medina, and put to scorn the armies of Persia and Turkey. He saw that he might beat the Mamlukes, but he could not destroy them as long as they could retire to the desert and live at the expense of the inhabitants; and, on the other hand, whilst he was no stranger to the motive which induced the Porte to urge him to engage in an expedition against the fierce sectaries of the Arabian desert, which, it was confidently hoped, would end in his destruction, he was convinced that a refusal on his part to march against the enemies of the true faith, and to attempt the deliverance of the holy cities, would for ever ruin him in the opinion of all good believers. In these circumstances, and impelled by the most powerful motives, he resolved to prepare the way for the distant enterprise prescribed to him, by exterminating the enemy at his doors.[2]

But in order to succeed in his object, it was necessary to draw the Mamlukes to some place whence flight might be impossible; and in laying the snare the utmost caution and prudence were requisite, as a single false step, or the slightest precipitation, on his part, would have alarmed the suspicions of his intended victims, and baffled the whole scheme. Mehemmed accordingly commenced by gaining over to his side Selahin Elfi, whom he appointed commandant of Ghizeh, and loaded with valuable presents. The Mamlukes could not resist the effects of this example; all of them sighed after Cairo, and wished to exchange their wandering and comfortless mode of life for the pleasures of the capital. The aged Ibrahim warned them of the fate which awaited them, if, without due precaution, they placed themselves in the power of the perfidious pasha; and the projects of the latter were several times baffled by the cautious and experienced Bey. But the profound dissimulation and artful management of Mehemmed ultimately prevailed over the admonitions of the veteran chief; and, about the beginning of 1811, the greater part of the Beys, with their suites, repaired to Cairo. Here they celebrated in festivities the remembrance of their ancient power, and appeared even to brave the pasha himself, who, having assembled an army to march against the Wahabis, was preparing to review it previously to its departure. At length the first of March arrived. This was the day named for the investiture of Toussoun, the viceroy's favourite son, upon whom the Porte had conferred the dignity of pasha of two tails, and who had been appointed by his father to the command of the army destined to serve in Arabia. Four persons only were admitted into the secret. At the time appointed, all the grandees, military chiefs, and Mamlukes, arrayed in their splendid uniforms, proceeded to the citadel, and were ushered into the hall of audience, where they offered their congratulations to the pasha, who received them with great apparent affability. When the ceremony had concluded, the signal for departure was made by the viceroy, and the column, in the midst of which were the Mamlukes mounted on their superb chargers, descended by a narrow road cut out of the rock, and leading from the citadel to the gate of El Azab and the square of Roumeyleh. As soon as the head of the column had entered Cairo, the gate of El-Azab was shut, and the chief of the Albanians, Saleh-Koch, apprized his soldiers in a few words that the pasha commanded them to exterminate the Mamlukes. Without uttering a single word the Albanians immediately ascended the steep sides of the road, which they promptly lined; and scarcely had this moment apprized the Mamlukes of the danger which menaced them, when a terrible fire was directed against them from the ramparts of the citadel, as well as from the heights which commanded the road. Confined in this gulf, into which there now rained a deluge of fire, the Mamlukes sprung from their horses, which became unmanageable; tore away the lower garments which impeded their movements; and attempted, in their turn, to mount the rocky acclivities on either side of the road. But all their efforts were unavailing. Half-naked, with their sabres in their hands, they clambered up the heights, and died frantic with rage and despair at not being able to reach their enemies.

Scarcely had the column begun to defile from the citadel when the pasha's movements betrayed his anxiety; and on hearing the first discharges of musketry his agitation redoubled, his visage became deadly pale, and his lips quivered. It was indeed a terrible moment. He knew the value of his enemies; success might be doubtful; his orders might not be well executed; the frantic energy of despair might overthrow all his combinations. He was in the very crisis of his fate; his own existence and that of his family depended on the issue of the combat, which he had so treacherously commenced; and no safety remained for him except in the complete execution of the general massacre which he had planned, not only in Cairo, but throughout all Egypt. Whilst matters remained in suspense, therefore, a thousand appalling apprehensions appear to have arisen in his agitated mind. At length heads, the usual signal of victory, were brought, and laid at his feet. But the sight of these bloody trophies, though it appears to have somewhat abated his terrors, did not restore serenity to his countenance. In a little time Mendrici, one of the pasha's physicians, entered his apartment, and warmly congratulated him on the success of his enterprise. "The affair is finished," said the Genoese, with an air of gaiety; "this is a day of rejoicing for your highness." Mehemmed made no answer to the heartless remark of the Italian, but looking around in a dark and suspicious manner, seemed apprehensive lest some Mamluke, escaped from the carnage, should come to avenge upon him the slaughter of his comrades. Twenty-three Beys and more than a thousand Mamlukes were the victims of this bloody day. Having finished their task of butchery, the Albanians entered Cairo in triumph, and, under the pretext of searching for Mamlukes, penetrated into the houses and committed all sorts of excesses. For two days the city was abandoned to pillage, and not less than five hundred houses were sacked by the licentious soldiery. At length Mehemmed descended from the citadel with an escort, and, preceded by executioners, traversed the city, where he re-established order, and received the felicitations of the sheikhs and the ulemas, over the bloody corpses of his enemies.[1]

[2] Mengin. Russell. *Bulletin des Sciences Milit.* ubi supra. *Zeitschrift*, &c. 1831.

Such was the tragical scene which formed as it were the denouement of the complicated drama of intrigue, dissimulation, treachery, and cruelty in which Mehemmed had all along been the principal performer; and thus was in a great measure attained the object to which all his actions had constantly tended, namely, the destruction of the Mamlukes. The remains of this unfortunate militia, pursued by the viceroy's troops, passed the Cataracts, and threw themselves into Nubia; but being quickly followed, they were overtaken in their retreat, and again defeated with great loss. Their repeated misfortunes, however, seem at length to have restored to them somewhat of their original energy; for, issuing from the deserts, they afterwards appeared in Dongola, and took possession of the country, of which, however, they were only able to occupy a part. Ibrahim, the oldest of the Beys, died at the age of eighty-four. But the Mamlukes, though now reduced to a small number, had not yet exhausted the hatred of Mehemmed. His son Ismaël, in carrying his arms into the interior of Africa, attacked them once more in 1820, and compelled them to abandon their new country. This was the finishing blow. The few who had escaped so many casualties dispersed, and from this time the Mamlukes as a body ceased to exist. Originally formed in the middle ages, this intrepid cavalry ever afterwards entertained for infantry the contempt which that arm then merited; and its fall is principally to be ascribed to the circumstance that, whilst infantry had been greatly improved in discipline and stability, it had neglected to make any corresponding change either in its organization or manner of fighting. Hence the French infantry wrested Egypt from its hands, and the Albanian infantry completed its ruin. Still, considered merely as a body of horse, the Mamlukes continued to the last to maintain the reputation which they had originally acquired, as at once the finest and most daring cavalry which the world had ever seen.

The massacre of the Mamlukes, and the measures subsequently adopted for completing their destruction, having effectually secured the viceroy against all danger from the enemies whom he most dreaded, he now found himself at liberty to devote his attention to the state of affairs in Arabia. Thither Toussoun Pasha had, as already stated, been sent to command the army destined to act against the Wahabis;[2] and the campaign, though somewhat inauspiciously commenced, had already been attended with some success. After the battle of Safra, Toussoun had been compelled to retire to Iambo; but having received reinforcements from Egypt, he resumed the offensive, and advanced towards Medina, of which he soon made himself master. Having dispatched one of his officers to Constantinople with the keys of Medina, and large presents of money, jewels, and coffee for the sultan, Mehemmed set out in person for Arabia; and having crossed the Red Sea, he proceeded to Djidda, where he was received with the utmost kindness and hospitality by the Scherif Ghaleb, in return for which the latter was arrested by order of the pasha, deprived of his office, and sent as a prisoner to Cairo, probably from a suspicion of entertaining treasonable designs. But whatever may have been the cause, the palace of the scherif was plundered of immense treasures, part of which were applied to the support of the army, and part also transmitted in the shape of presents to the sultan. When the latter, however, came to understand how these had been acquired, he dispatched a capidji with a firman ordaining the viceroy to restore the property to the rightful owner. From Djidda, Mehemmed proceeded to Mecca, in order to pay his devotions at the shrine of the Prophet; and having thus acquired the character of Hadji, he assumed the command of the army, which, under Toussoun, had recently experienced some reverses, His presence in the camp restored discipline and confidence among the troops; disorder ceased, their spirits revived, and, anticipating victory under such a leader, they longed for an opportunity of revenging their losses, and obliterating the recollection of their defeats. Nor did it suit the views of the viceroy to baulk their wishes in this respect. As soon as he found himself in a condition to take the field, he concentrated his forces, and marched against the Wahabis, whom he routed and put to flight. The main body of the Turkish army then entered the country of the Nedjd, whilst Toussoun, at the head of a division, marched on El-Rass, which he took by a stratagem, but was afterwards obliged to evacuate from want of provisions. The Wahabis, finding that the fortune of war had thus turned against them, now made proposals of peace; and, with a view to a negociation, an armistice was agreed to. But as it soon became evident that their principal object was to gain time, Toussoun, who, in the interval, had received reinforcements and supplies of all kinds from Medina, resolved to march against the enemy and to give them battle. This brought the latter to their senses; a negociation was opened, and as Mehemmed had urgent reasons for treating, peace was speedily concluded between him and Abdallah-ebn-Souhoud, chief of the Wahabis; after which the pasha immediately took his departure for Egypt, where his presence had become necessary. In the depths of the Arabian desert he had received intelligence of the return of Napoleon from Elba; and as he foresaw that this event would plunge Europe again into war, and knew that, even to the moment of his fall, Bonaparte had cherished the hope of recovering Egypt, he set out with all haste from Medina, sailed from Djidda for Cosseir, and arrived at Ghizeh on the 18th of June 1815, the day of the battle of Waterloo. The following morning he made his public entry into Cairo.

[1] Mengin, *Histoire de l'Egypte sous Mahommed-Aly*, tom. i. pp. 363, 364, et seqq.; *Life and Adventures of Giovanni Finati*, vol. i. p. 101, et seqq.; *Abrégé de l'Histoire des Mamlouks; Bulletin*, tom. x. pp. 223, 224. The account of the massacre, contained in the "Adventures of Finati," differs in some particulars from the less picturesque but probably more accurate account of Mengin, who was on the spot at the time, and an eye-witness of part of the tragedy. In the text we have chiefly followed the *Abrégé*, which appears to have been compiled, with singular care and accuracy, from the best authorities.

Many anecdotes have been told of the conduct of the Mamlukes on this dreadful occasion; but the most remarkable is that which relates to Amim Bey, brother to the celebrated Elfi, and the only one of the Beys who escaped the massacre. Being detained by business, he was too late to occupy his proper place in the procession, and he only arrived in the citadel when the troops were defiling through the gate on their return to the city. Having reined up his charger, he waited until the column had entered the hollow road, intending to join his own body; but seeing the gate suddenly closed, and all retreat intercepted, whilst discharges of musketry immediately followed, the gallant chief, preferring to be dashed in pieces rather than to be slaughtered by concealed enemies whom it was impossible to reach, urged the charger which he rode until the horse clambered upon the rampart, when, spurring the noble animal to desperation, he leaped headlong down the precipice, a height of more than forty feet. The horse was killed on the spot, but the rider remained unhurt, and, having made his way into the city, at length succeeded in effecting his escape to Syria. The desperate leap which Amim took from the parapet of the citadel has been compared to leaping out of a four-pair-of-stairs window. According to another account, the Bey was received and sheltered by some Arabs, who, notwithstanding the offer of a large reward, refused to deliver him up. (Finati, p. 64.)

[2] In the year of the Hegira 1110, or of our era 1691, a sheikh of the village of El-Ayeyneh had a son, named Mohammed-Abd-el-Wahâb, whom he destined to succeed him. The youth was initiated by his father in the elements of Islamism, and afterwards sent to college at Bassorah, there to complete his studies. Having finished his education, and performed the pilgrimage to Mecca and Medina, he returned to his native country, but afterwards withdrew to Horymlâ, where he took unto himself a wife. In this new retreat he undertook to reform the manners of the inhabitants, who, however, far from relishing his maxims, forced him to take refuge amongst his countrymen. But he did not remain long among the latter, having been banished by orders of the governor of the province of El-Hassan, who was incensed at an act of barbarity which he had caused to be committed. In this conjuncture, Abd-el-Wahâb accepted an asylum which had been offered him at Derayeh or Deraeyeh, the capital of the Nedjd, by Mohammed-ebn-Souhoud; and it was in this city that he commenced the exposition of those principles of reform which were soon to exert so powerful an influence over Arabia. The emir Souhoud had calculated that, favoured by a change of religion, he might be enabled to extend his possessions; nor was he disappointed in his expectations. From all parts ardent sectaries came to offer their arms and their services to the inspired sheikh; and in a short time the villages of El-Ayeyneh, Horeymlâ, El-Ammaryeh, and Manfouah had received his doctrine. On his part, Souhoud directed his views towards the Nedjd, and made incursions into the neighbouring provinces, most of which were attended with success. The emir died in 1765, leaving the power to his son Abd-el-Aziz, who had already signalized himself in several military expeditions, the command of which had been entrusted to him by Ebn-Souhoud. This young prince, aided by his son, enlarged the dominions which had been left to him by his father, and greatly increased the Wahabite power. He imposed tribute on his neighbours, took possession of El-Ryad and El-Delem, seized on the province of El-Kharg, and ruled over all the surrounding tribes. Being a witness of these triumphs, which ensured the success of his reform, and grateful for the services which Souhoud the son of Abd-el-Aziz rendered to his cause, Mohammed-Abd-el-Wahâb collected the principal inhabitants of Derayeh, in order by their means

Mehemmed Ali, well aware that tactics often supply the place of numbers, and that bravery without discipline is alike unmanageable and unavailing against regular troops, had long had the intention of clothing and instructing his troops in the European manner; and indeed, from the period of his first accession to power, he had encouraged the formation and training of Turkish and Albanian troops according to the Frank discipline. But it was only after his return from Arabia that his determination was manifested in a formal manner. Having secured the services of several French officers who had been trained in the school of Napoleon, he repaired to Boulak on the 2d of August, and, after some preparatory exhortations, he began to exercise the troops of his son Ismaël. These he put through some evolutions, at the same time declaring that he wished to establish among them the nizam-jedid, and that whosoever should disobey his orders would be severely punished and then expelled from the army. The troops murmured, but Mehemmed remained firm. A regular course of drilling was immediately commenced, and enforced with all the rigour of oriental despotism, whilst the success of his arms encouraged him to persevere. But excessive pressure at length wrenched off the head of the screw, and the spring recoiled with tremendous force. The soldiers mutinied, murdered their officers, plundered Cairo, and marched in a body towards the citadel for the avowed purpose of putting Ali to death. Fortunately the pillage of the bazars attracted their attention in the first instance; the chiefs of the government, who were quite unprepared for an attack, had time to recover from their

---

to ensure to this prince the succession of Abd-el-Aziz; and he died several years afterwards (14th June 1787), at the advanced age of ninety-five. But this event did not diminish the zeal of the followers of his doctrine; and such was the terror which the Wahabis inspired on all sides, that the towns in the neighbourhood of Bassorah were obliged to implore the protection of the Pasha of Bagdad, who, in 1796, caused a considerable army to march against the heretics. The troops of the pasha were however repulsed by Souhoud, who, encouraged by this success, ventured the following year to make an incursion into the province of El-Irak, situated between Bassorah and Bagdad, where he committed dreadful ravages with impunity. The Scherif Ghaleb, who had long struggled in vain against the growing power of these formidable enemies, was constrained to make peace with their chiefs; and Salem-ebn-Schekban of Byeheh felt himself equally obliged to submit to the prince of Derayeh. Intoxicated with these successes, Aziz now wished to attack the Persians as well as the Turks; and accordingly he sent his son at the head of 20,000 men, who directed their march upon Kerbeleh. On the 20th of April 1810, the Wahabis took possession of this city, which the Persians account sacred, as containing the tomb of Ali, and put all the male inhabitants to the sword. Souhoud, thinking that he had not yet done enough, next directed his march towards Mecca, forced the Scherif Ghaleb to fly, and interrupted the most sacred ceremonies of Islamism. Meanwhile the sacrilege which Abd-el-Aziz had committed in the eyes of the Persians did not pass unpunished; for a fanatic having undertaken to avenge the violation of the tomb of Ali, proceeded to Derayeh, and poignarded the prince whilst he was reciting his prayers in the mosque. But Souhoud in his turn swore to avenge the death of his father. Accordingly, having assumed the chief command of the Wahabis, he marched the following year against Bassorah, without being intimidated by the menaces of the Shah of Persia. The Scherif Ghaleb thought the moment favourable for striking a blow in retaliation of the injury he had sustained; but the check which his arms experienced constrained him to sue for peace; and soon afterwards he was under the necessity of submitting entirely to Souhoud. The latter, at the head of 40,000 men, now made a pilgrimage to Medina, in order at the same time to prevent the arrival of the caravans; and left in that city one of his generals whom he appointed governor. From Medina he proceeded to Mecca, and after having there piously fulfilled all the duties of the pilgrimage, he caused the tomb of the Prophet to be broken open, and unscrupulously took possession of the riches it contained. Such acts of sacrilege, boldly committed, and frequently repeated, roused the indignation of the whole Moslemin world; and the viceroy of Egypt was in consequence enjoined by the Porte, as above mentioned, to march against the audacious heretics. The Wahabis are a sect of Mohammedan Socinians, who regard all pilgrimages, relics, ablutions, and other outward ceremonies or symbols, as rank idolatry, and who, professing the principles of pure deism, reduce the whole duty of man as a religious being, to prayer and good works. (Mengin, *Hist. de l'Egypte sous le Gouvernement de Mohammed Aly*, tom. i. p. 378, et seqq. For an admirable account of the Wahabis, see also *Anastasius.*)

surprise; and the pasha, apprised of the revolt while at his palace of Ezbekyeh, caused arms and ammunition to be distributed amongst the inhabitants of the Frank division of the capital. His palace was indeed attacked; but the guard, having thrown up entrenchments, repulsed the assailants; and the viceroy had previously quitted it for the citadel, which he entered by the mountain gate, accompanied by a numerous escort. Here he was in comparative safety; but he had nevertheless to endure many bitter hours of anxiety and suspense; and, as he could not know how far the mutinous spirit had extended, nor confide even in those around him, he must have felt that he was liable every moment to be dragged forth and torn in pieces. When the fury of the revolt had somewhat exhausted itself, and the sated indignation of the mutineers had momentarily subsided, Mehemmed re-appeared; and the full force of his character may be understood from the union of wisdom and firmness which he displayed on this critical occasion. He showed neither fear nor anger, distrust nor indignation; but immediately issued a proclamation, pledging himself, if the troops would return to their duty, to discontinue the obnoxious system, to grant a general amnesty, and to indemnify the merchants and inhabitants who had been pillaged, for the losses they had sustained. This declaration produced the desired effect; the troops gladly availed themselves of the proffered pardon, coupled as it was with the promised abandonment of the European discipline; Cairo was restored to tranquillity; and as the number implicated in the guilt of disaffection was too great for punishment, even by way of example, the viceroy wisely judged it prudent to adhere strictly to the conditions of the amnesty he had proclaimed. No pains were spared by the government, however, to discover the prime movers and ringleaders of the revolt; and notwithstanding the assertion of Finati, that no clew was ever obtained that could lead to the detection of the principal instigators of the mutiny, there is some reason to believe that they were not unknown to the pasha; for it was observed that, shortly afterwards, several persons died sudden deaths, and many of the chiefs and Beys disappeared, no one knew how or by what means.

The treaty which had been hastily concluded with the Wahabis proved of short duration; indeed scarcely had the Egyptian army retired, when the fierce and warlike heretics of Derayeh again flew to arms. At the head of forty thousand of these sectaries, Souhoud marched to Medina, which he obliged to open its gates; and following up his success, he proceeded to Mecca, which he took with as little difficulty. At the latter city he broke open the tomb of the prophet; abstracted numerous jewels, such as diamonds, rubies, and emeralds, which had long been venerated by all true believers; melted the golden vessels, chandeliers, and vases; and having exposed the whole to public sale, distributed the money amongst his soldiers. Nor was the former city treated with more respect by these Mahommedan schismatics, who despised all outward show and parade in matters of religion, placing their whole reliance on the joint efficacy of prayer and of good works. As might have been expected, such bold acts of sacrilege excited against Souhoud the indignation of every true Moslemin; and the government at Constantinople, fully as much alarmed at the progress of his arms, as shocked at his impieties, immediately sent orders to the viceroy of Egypt to chastise the daring heretic, and to deliver the holy cities out of his hands. An army was accordingly assembled and marched into Arabia under the command of Ibrahim Pasha, Toussoun having fallen the victim of either disease or poison. Notwithstanding the motley composition of his force, Ibrahim, who now entered upon that career of victory which has since rendered him so celebrated as a commander, succeeded in accomplishing all the objects contemplated by the expedition. Having concentrated his troops at Henakeyeh, he marched on El Mayoueh, which he occupied in force, at the same time baffling an attempt made against it by the Wahabite chief; and soon afterwards laid siege to El-Rass, which he thrice assaulted, but without success. The situation of the Turkish army now became critical; but although Ibrahim felt himself under the necessity of raising the siege, he nevertheless rejected proposals of peace which were made by Abdallah-ebn-Souhoud. But though baffled before El-Rass, the Egyptian commander took in succession Khabra, Aneyzeh, Boureydeh, and laid siege to Chakra, which capitulated in a few days. He then marched against Dorama, which he carried by assault, and sacked, putting the inhabitants mercilessly to the sword. From Dorama he proceeded to Derayeh, the capital of the Wahabis, which he besieged. This was the grand operation of the campaign, and here accordingly he met with the most determined resistance. For three months did the brave defenders successfully repulse every attempt to take the town; and all the efforts of Ibrahim would have been unavailing had not want at length compelled them to surrender. With the capture of this place the campaign against the Wahabis terminated; but not so the severities of Ibrahim, who is remembered as the scourge of Arabia and the destroyer of Derayeh. In a moment of passion the viceroy had threatened to exterminate the heretics, and not to leave one stone upon another of their city. The former part of this menace Ibrahim found it impossible to execute, but the latter was carried into effect to the fullest extent. The unfortunate Souhoud was sent as a prisoner to Constantinople, where he was beheaded like a common malefactor, notwithstanding the viceroy had interceded for his pardon; those of the inhabitants who had escaped the sword were driven into the desert, where many of them perished; and Ibrahim, having spread far and wide the terror of his name, returned in triumph to Egypt.

But excessive severity generally defeats its object. The cruelties of Ibrahim, so far from extinguishing the Wahabite reformation, appear only to have inflamed and exasperated the spirit of resistance by which it was animated. Hence in 1824 the war was renewed with as much ferocity as ever, and protracted during the three following years, in which it was carried on with various success. Latterly, however, owing to the struggle made by the Greeks to recover their liberty, and the consequent detention of the troops under Ibrahim in the Morea, the contest was allowed to slumber, and at length it terminated with the capture of Mecca, which was effected under the direction of a French officer. Achmet Pasha, who commanded in chief, was very inferior to Ibrahim both in genius and enterprise; and although he frequently defeated the enemy, he wanted the skill and address necessary to enable him to profit by victory. The only relation of these campaigns is that of Planat, which is exceedingly meagre, and, excepting an itinerary of the marches and countermarches of the pasha, contains few particulars deserving of attention.

The mutiny at Cairo, though it had had the effect of interrupting the execution of the viceroy's scheme for introducing the European discipline, did not lead to the abandonment of the design. Mehemmed was resolved to possess a regular army trained on the European model, and when he found the Turks and Albanians unmanageable, he applied himself to the natives of Egypt. He had the good sense to attribute his first failure to the imprudent rigour which he had employed; and, therefore, he resolved to change his system, and to make his military projects popular by rendering them desirable. His next object was to secure the services of an European officer properly qualified to lay the foundation of that revolution in tactics which he now meditated; and in Colonel Sèves he was fortunate in finding an officer exactly suited to his purpose. In 1818 or 1819 Sèves, the son of a miller at Lyons, formerly a lieutenant-colonel of cavalry in the French army, and aide-de-camp to Marshal Ney, an officer of approved courage and of an intrepid and enterprising character, having been persecuted in his own country, and forced to expatriate himself, went to seek an asylum in Egypt; and he was living in great misery at Alexandria, when the pasha arrived there some time after his landing. Having learned that a superior French officer had come to seek an asylum in his territory, Mehemmed, who was then meditating the project of reform which he afterwards adopted and carried through with so much success, sent for Sèves, received him graciously, and granted him an allowance of L.200, without any definite employment. The only duty which he had at first to perform was to answer the questions which the pasha frequently put to him respecting the Emperor Napoleon, his victories, his armies, and the French empire. Several months passed in this way, and Sèves was puzzling himself to account for so much munificence without any apparent motive, when Mehemmed, who had been long meditating an excursion into Upper Egypt and Sennaar, sent for him, and inquired if he would undertake to organize some regular battalions in the Egyptian army. Happy to be employed, and pleased to have an opportunity of testifying his gratitude towards his benefactor, Sèves at once agreed to make the attempt; and being provided with money and invested with unlimited power, he at once applied himself to the task which he had undertaken. He associated with himself several French and Italian non-commissioned officers, who were exercising various professions at Alexandria, and with their assistance commenced his work. His first battalions were raised out of a great number of vagabond Turks and Arabs, the only class indeed to which he could apply; and out of these the instructors selected the most intelligent, in order to form them into model platoons, and also prepare them to act as sub-instructors. Sèves and his assistants had to surmount the greatest difficulties, obliged as they were to take man after man without distinction, and thus to enact a sort of pantomime. The repugnance of the Turks to these innovations was inconceivable, and often manifested itself by the most violent acts. The lives of the instructors, indeed, were frequently in danger; and several musket-balls were fired point blank at Sèves, who escaped as if by a miracle. But he was not to be intimidated in the discharge of his duty; and, amidst dangers of every kind, he went straight to his object with unflinching intrepidity and perseverance.[1] At length, in about a year, several battalions appeared in line, armed with English, Austrian, and French muskets, and with sabres of all sorts and models.

Such was the nucleus of the disciplined army which Mehemmed Ali now possesses, and which has amply rewarded him, by its brilliant successes, for the liberality and wisdom which presided in its formation. Nor did the viceroy lose any time in making a trial of the new battalions, in the long-projected expedition to Upper Egypt. Ismaël Pasha, his second son, assumed the command of the army; Sèves, however, directed the campaign; the regular troops carried all before them; and Upper Egypt was conquered. The viceroy had promised a brilliant recompense to Sèves if the Egyptian army returned victorious from Sennaar; but, in point of fact, Mehemmed gave him none, and in this he obeyed the imperious law of necessity. The instructors could hold no command in the army unless they embraced Islamism; their authority was confined to the ground on which the troops were manœuvred, and, in actual service, to the council of war. The pasha durst not trample under foot the prejudices of his subjects, whose fanaticism he was far from sharing; whilst, appreciating the merit of Sèves, afterwards known by the name of Soliman, he felt the necessity of giving that officer a superior command in the army. To reconcile every thing therefore, he proposed to the Frenchman to abjure the Christian religion, at the same time promising him a brilliant fortune, the title of Bey, and other tempting advantages, in the event of compliance. Sèves, however, rejected the viceroy's proposition, and was immediately dismissed from all his employments. But, partly by poverty, and partly also by the influence of Drovetti, consul-general of France, his scruples were at length overcome, he became a Moslemin, was raised to the dignity of Bey, and received the command of a regiment of infantry. But although Soliman-Bey (Sèves) was endowed with the energy and capacity necessary to conduct the instruction of the Egyptian army, nevertheless, it was only after the arrival of General Boyer, in the year 1824, that it really began to assume consistence. In a short time this officer performed wonders. The army increased in numerical force, in *moral*, and in discipline; the instructors, respected and well treated, laboured with increased zeal and success; and when the troops were ordered to take the field, these men marched at their head against the enemies of the pasha. To Domergue, a French officer, born at Carcassonne, the viceroy owed the conquest of Mecca and of the country of the Wahabis; whilst, on the other hand, it was the Marquis of Livron, agent of the pasha in France, who supplied every thing necessary for the *matériel* of the army, and who provided the pasha with artillery instructors and with surgeons.[2]

The preparations for the war in the Morea determined the pasha to augment his regular troops; and a great number of Piedmontese and Neapolitan refugees having about this time arrived in Egypt, Ali soon acquired a formidable and well-appointed army. It was in part destroyed, however, during the campaign in the Morea; but he afterwards added nine regiments of cavalry, and at present it is finer and stronger than ever.

According to an authentic statement published in 1831, the Egyptian army is composed of a general staff; of infantry, including artillery; and of cavalry. Ibrahim Pasha is commander-in-chief of the army; and the sons or relations of the pasha are the only lieutenant-generals with the title of pasha. Each brigade of infantry or cavalry has its general. Two regiments compose a brigade, and the regiments of guards are each commanded by general officers. The total number of the latter, therefore, is fifteen, with rank equivalent to that of major-general. The artillery has two generals with the title of Bey, one of whom is the director, and has the inspection of founderies, laboratories, workshops, arms, and the like. The infantry is composed of a regiment of guards and fourteen regiments of the line, each consisting of four battalions of a thousand men; thus making a total of fifty-six thousand. The artillery, with the train, consists of one regiment of six thousand men, and the engineers of two battalions of six hundred each, besides a company of artificers two hundred strong, and a company of gendarmerie of the same force. The cavalry, which has only been formed since 1828, is by no means equal to the infantry. It is composed of a regiment of guards, of four squadrons, each consisting of four troops, into which Turks only are admitted, and eight regiments of the line, forming four brigades, making, with supernumeraries, four thousand five hundred men and horses. The total strength of the Egyptian army is therefore 67,600 infantry, and 4500 cavalry.[1]

---

[1] On one occasion, when a volley was fired, a ball whizzed past the ear of Sèves, so close as almost to graze the skin. Without betraying the slightest emotion, or taking the least notice of the circumstance, he ordered the party to re-load their pieces, and merely saying, "You are very bad marksmen," gave the word to fire. They did so; and no ball was now heard to hiss through the air. The cool courage of the Frenchman disarmed their resentment; and, from being an object of the deepest hatred, he became the idol of their admiration. (Planat, *Histoire de la Régénération de l'Egypte*, p. 28.)

[2] *De l'Egypte et de son Organisation Militaire.* Paris, 1831.

This army is recruited by a stern system of impressment, the most arbitrary and iniquitous which can well be conceived; yet, excepting at the moment of its operation, it is scarcely felt as an evil. Once with the regiment, the young soldiers soon become reconciled to their new mode of life; they acquire a taste for the service, and speedily forget, in the enjoyment of the comforts provided for them, the violence which tore them from their miserable homes. They are excellently clothed, have abundance of wholesome food, and even exercise a sort of superiority over their countrymen. A soldier is a kind of authority; he in fact makes the law; and the people tremble before an uniform. Hence in this army, thus recruited by violence, there are scarcely any desertions. Besides, the Arabs, of whom it is principally composed, are intelligent, observing, inquisitive, brave; they love the service, both for its immediate advantages, and also because promotion from the lowest to the highest ranks is thrown open to all; they feel that they are men, and already begin to lay aside that fanaticism which at first opposed the most formidable obstacle to the success of the viceroy's plans. The only danger to which Mehemmed is exposed appears to consist in the tendency of such elements to too great a transition, and in the formation of opinions incompatible with the existence of even an enlightened despotism. But whilst the reins of discipline are held by a steady and vigorous hand, there will be little ground for alarm on this score; though any undue relaxation would, in all probability, be productive of the greatest misfortunes. The chief hazard to Mehemmed's system arises from this, that it is so closely connected with, and dependent upon his personal character. But he may leave a successor worthy of his talents.[2]

With a view to the consolidation of his military reforms, the viceroy has established a number of schools and colleges, the principal of which we shall now briefly advert to. The school of the staff is at Kaukeh. It contains an indeterminate number of pupils, and is provided with professors of mathematics, fortification, and design; branches which, however, are as yet but indifferently taught. A cavalry school has been organized at Ghizeh, in the palace of Murad Bey, and is under the orders of a French cavalry officer named Varrin. It contains a hundred pupils, who, during a course of two years, are instructed in military equitation, hippiatrics, and cavalry evolutions; but hitherto no great progress has been made in any of these branches. At Bouzah-a-Bel there is a school of surgery, the object of which is to supply the regiments with surgeons. The pupils show address and good will; but their teachers allege that, when left to themselves, they become good for nothing. This school is under the direction of Dr Clot of Marseilles, a man of great merit and undoubted knowledge. A school of pharmacy has also been opened at the same place, under the superintendence of an Italian named Alexandri. The school of veterinary surgery is likewise established at Bouzah-a-Bel, and is under the management of a Frenchman named Hamont, an élève of the school of Alfort, and a man of merit. Besides these, there was a school of military music at Kaukeh, for training regimental bands; but, in 1829, Ibrahim Pasha ordered it to be suppressed, probably from motives of economy; and the only establishment of the kind at present in existence is a school of trumpeters, in the camp of Soliman-Bey, where a hundred pupils are trained according to the French mode.

The pay, appointments, and clothing of the Egyptian army are not only equal, but in several respects superior, to those of any army in Europe. The monthly pay of a general, or, to speak more correctly, the pay from one moon to another, is L.120 besides rations; that of a colonel is L.90, that of a lieutenant-colonel L.30, that of a captain L.10, and that of a lieutenant L.3, exclusively of rations. A general receives fifteen rations a day, a common soldier one, and the intermediate grades in proportion to their relative positions in the scale of rank. The pay of the non-commissioned officers is likewise ample; and that of the common soldier is eighteen piasters a month, besides his daily rations and his clothing. The ration is composed of bread, rice, oil, butter, beans, salt, and meat, and is served out twice a week. The clothing of the army is excellent, and the dress of the officers superb. The uniform of the generals, as well as that of the Turkish officers, is scarlet embroidered with gold; all the difference consisting in the quantity and richness of the embroideries. The distinctive marks of military rank are crescents and stars. Those of a lieutenant-general are crescents enriched with diamonds, in the middle of which are placed three stars, also in diamonds; those of a brigadier-general are the same crescents with two stars only; those of a colonel are the same crescents with only one diamond star; those of a lieutenant-colonel are two crescents in gold with a star in diamonds; those of a major are two crescents with stars in gold; those of a captain two crescents and stars in silver; and those of lieutenants and sub-lieutenants a crescent in silver. These decorations are placed on both breasts, and have a very brilliant effect. On occasions of ceremony, the superior officers also wear scarlet pelisses, fastened with two large clasps of gold set with emeralds. The loins are begirt by a sash; and the Turkish papooshes have given way to a less voluminous and more convenient nether habiliment, which is made fast under the knees, and fitted close to the legs.

---

[1] Military men will no doubt remark the great disproportion between the infantry and cavalry of the Egyptian army; but it ought to be kept in view that we only speak here of the regular army, and not of the whole forces which Mehemmed Ali has at his disposal; and that, moreover, the battalions of infantry had been ten years in line ere the model squadron of cavalry began to be organized. When the cavalry was formed, Captain Thurlet of the 13th regiment of French chasseurs, happening to be in Egypt, was charged with its organization; but as this was a task beyond his ability to execute, the Marquis de Livron was commissioned to engage three *chefs d'escadrons* to complete the instruction of the brigades, and accordingly sent out Deschales, Petit, and Touchebœuf-Clairemont, who are now the only superior officers attached to the cavalry. The subaltern officers were taken from the infantry, from the schools, and from the counting-houses of Alexandria, where a number of discharged military men, whom the Restoration of 1815 had forced to quit France, were employed as clerks. The horses of the cavalry are in general excellent, and they are classed in squadrons according to their shades of colour. (*De l'Egypte et de son Organisation Militaire.* Paris, 1831.)

[2] *De l'Egypte et de son Organisation Militaire. Bulletin des Sciences Milit.* tom. x. p. 270.

In point of arms and equipment the infantry, cavalry, artillery, and engineers resemble the corresponding branches of the French service, upon which, indeed, the whole has been modelled; and the same observation applies to the mode in which the troops are disposed, whether in cantonments or in camps. Nor are the men any longer liable to arbitrary punishments. Every soldier charged with a breach of military discipline must be tried before he can be bastinadoed, and some other penalty less degrading, as confinement, degradation, or hard labour, is generally inflicted. Officers, again, when accused of a dereliction of duty, are placed under arrest; and the question of their guilt or innocence is commonly left to the determination of a court-martial. By these wise provisions the moral character of the Egyptian army has been raised to a level with that of the best troops in Europe; and its devotion (as already stated) has been further secured by the impartiality with which promotion is bestowed, and by the highest grades of the service being thrown open to the ambition of the humblest soldier in the ranks.[1]

Nor in thus organizing a powerful army has the viceroy neglected to provide himself with a respectable navy. His ambition, indeed, has all along been to raise Egypt to the rank of a naval power; and it was no doubt principally with this view that he seems to have early resolved to possess himself of Syria; a country which, from its extensive line of coast, and its internal resources for ship-building, afforded every facility for the development and execution of his plans. As early as the year 1824, he had accordingly either acquired by purchase, or caused to be built for his service, a considerable number of ships of war; and, notwithstanding the disaster which befel his squadron at Navarino in October 1827, he prosecuted his original design with such systematic perseverance, that he not only repaired the loss he had sustained, but greatly augmented his marine both in number and in force. According to the most authentic information which we have been able to obtain, therefore, the Egyptian navy consists at present (1833) of twelve sail of the line, one of which is a first-rate carrying a hundred guns, about as many frigates, some of them double-banked, and a great number of corvettes, brigs, schooners, and sloops of war; a naval force equal, if not superior, to that of the Porte itself, and which, in fact, during the Syrian campaign of Ibrahim, defeated the Turkish fleet off Tripoli, thereby contributing in the most essential manner to the success which crowned the pasha's enterprise.

The superiority of troops disciplined according to the European method was strikingly evinced by the results of the expedition to Upper Egypt and Nubia, and still more by those of the concluding campaigns against the Wahabis, which fully realised the most sanguine expectations of the viceroy. But the prowess and efficiency of that army which had been alike victorious in the deserts of Arabia, and in those of Dongola and Kordofân, were destined to be further proved on a much more celebrated theatre of action. The sultan having required the pasha of Egypt to assist with his forces in putting down the insurrection in Greece, an expedition consisting of sixty ships of war of all sizes, and a hundred transports, having on board seventeen thousand infantry, eight hundred cavalry, and artillery both for service in the field and for sieges, together with ammunition and provisions for a long campaign, sailed from Alexandria in July 1824, the whole being under the command of Ibrahim Pasha; but having touched at Rhodes, in the hope of effecting a junction with the Capitan Pasha commanding the Turkish fleet, and the ships of war having suffered considerable damage in an encounter with the Greek squadron under Canaris, it did not reach Modon in the Morea until the end of February 1825. The events of the three campaigns which followed belong rather to the history of Greece than to that of Egypt. It will be sufficient to state here that Ibrahim was successful at nearly every point; that the strong places of the Morea had, almost without exception, yielded to his arms; and that his father was believed to cherish a design of establishing his own power in the Peloponnesus; when the treaty of London changed the aspect of affairs, and the naval battle of Navarino, fought on the 20th of October 1827, proved a most "untoward event" for the viceroy's designs, depriving him of the fruits which he expected to reap from Ibrahim's victories, and completely isolating the Egyptian army, which depended for its chief supplies on Alexandria. The final deliverance of the Morea was effected by the French expeditionary force of fifty thousand men under General Maison, which, having cleared the country of the Egyptians, delivered it up to the provisional government which had received or assumed the reins of authority in Greece.[2]

But if, yielding to the pressure of superior force, Mehemmed was compelled to quit his hold of the Morea, still he was not altogether a loser; for, during the campaigns in the Peloponnesus, his army acquired experience in all sorts of military operations, and may be said to have in some measure prepared itself for achieving those brilliant successes which lately shook the Ottoman empire to its foundations, and humbled the pride of Sultan Mahmoud. From the commencement of the contest with Turkey till the decisive conflict at Koniah, in which tacticos and irregular troops were equally overthrown, and the road to Constantinople completely uncovered, its career was one of uniform victory. The fate of Syria was decided by the battle of Damascus, which proved the great inferiority of the Turkish infantry; Aleppo opened its gates; the barrier of Mount Taurus, hitherto regarded as a rampart of Constantinople, was crossed; and, descending into the plains of Anatolia, Ibrahim swept onward like a torrent, until, arrested for a moment at Koniah by an enemy resolved to make a last effort to retrieve its reverses, he there completed the series of his winged victories, and beheld "Stamboul's diadem" almost within his grasp. The rest is too well known to make it necessary for us to enter into details. Denied the aid which he solicited from Great Britain, the sultan was reduced to the humiliating necessity of applying for help in his day of need to the power whose ambitious designs he had the most reason to dread; whilst Russia, eager to avail herself of the opportunity thus offered, of giving to her aggrandising policy in regard to Turkey a protective rather than an aggressive character, lost no time in responding to the sultan's demand; and, in a short space, the strange spectacle was exhibited of a Muscovite corps d'armée cantoned in the vicinity of Constantinople, and of a Muscovite fleet at anchor in the Bosphorus. The sultan was saved; peace was concluded; and the whole of Syria, with its dependent territories, rewarded the successful rebellion of Mehemmed Ali.

The individual by whom all this and more has been accomplished would, even under the most favourable circumstances, have been accounted an extraordinary man; and amongst Turks he is certainly to be regarded as little less than a prodigy. His own greatness, indeed, is the immediate result of a creative power vigorously but skilfully exerted, and almost invariably directed towards the accomplishment of some object calculated to promote improvement and advance civilization; nor has the general policy of his government been less distinguished for ability, address, and energy, than was the conduct of those great measures by means of which he regenerated Egypt, and laid the foundations of his own supremacy. His army alone is a wonderful achievement; his fleet scarcely less so: and if the brilliant victories of the one have rewarded that wisdom which knows how to amend a fault, and that liberality which, when judiciously exercised, is all-powerful in its influence on the human mind, the day is probably not distant when the triumphs of the other will cause the flag of Egypt to be alike respected in the Mediterranean and the Indian Ocean. But it is not by the splendour of his winged victories, nor the extent of his rapid conquests, that the name of Mehemmed Ali will be honoured and distinguished. His are much higher and more difficult achievements than mere feats of arms; his is a nobler and more enviable glory than that which is reaped amidst the strife and carnage of the battle-field. It was the proud boast of Napoleon that he found France in the kennel, and placed her in the van of Europe. But with more truth and less ostentation might Mehemmed Ali say the same thing concerning Egypt. Napoleon, indeed, found confusion, but, as observed by an able writer, still it was the confusion of brilliant materials. Not so the Albanian, who out of a mere chaos of ignorance, treachery, and ferocity, has formed a kingdom possessing a disciplined and victorious army of seventy-five thousand regular troops, with a respectable marine of twelve ships of the line and more than thrice that number of frigates and other vessels of war. Nor is this all. He has organized a vigilant police, by means of which Egypt, formerly a land of violence and bloodshed, has been rendered as safe as any part of England or France; he has established an active and vigilant administration of the laws, by which persons and property enjoy security; he has constructed roads, formed canals, and introduced manufactures; he has improved agriculture, extended commerce, and reared an industrious population; and, notwithstanding all the cost of his various establishments, and the heavy expenditure incident to a state of frequent warfare, he has forestalled none of his ordinary revenues. During his reign the exports and imports of Egypt have accordingly risen from a mere trifle to several millions annually. Eager to obtain useful information himself, he has diffused a thirst of knowledge amongst his subjects, by making the possession of it the indispensable condition of advancement either in civil or military employments; he has ministered to the mental wants of his people by the erection of schools and colleges in various parts of his dominions; and he has, from time to time, sent young men into Europe, not to ape its fashions or copy its manners but to study the laws, institutions, and practical working of modern civilization, and to carry back the results of their observation for the improvement of their own country. His government, it is true, is a naked despotism, and, with all its general wisdom and beneficence, exhibits some of the worst features of that species of government; whilst the unhappy Fellahs are still ruled, if not oppressed, by a rough coercive hand, and exposed to exactions indicating a short-sighted cupidity on the part of their rigorous taskmaster. But, on the other side, it must be admitted that the strong arm of absolute power, guided by a stern and resistless will, could alone have effected that renovation which has been produced in Egypt; and as to his exactions and monopolies, Mehemmed Ali may easily silence rebuke on this head by pointing to many scarcely less odious or objectionable than his own which are still selfishly upheld in some of the most enlightened communities of Europe. And let it also be remembered that, as establishments must be maintained, the chief cause of the severity of his imposts has been the extent of his improvements, by which in time their rigour will be mitigated; and that monopoly is the price which must in the first instance be paid for the introduction of new and more effective modes of industry. Nor have the actual results belied the calculations on which this enlightened and vigorous ruler has proceeded. A country long devoted to misrule now teems with labour, and produces cotton and flax which may compete with the best in our markets; it exports silk, sugar, tobacco, and various other commodities, besides grain; and as long as personal security is maintained by an impartial administration of the law, these will continue to multiply in a land where an annual renewal of the soil, irrigation, and sunshine are certainties. Such are the triumphs which have been effected by the Albanian peasant, who has established an independent empire in Egypt.[1] He is

---

[1] Mehemmed Ali is now in the sixty-third year of his age; he is rather short in stature, thick set, and inclined to embonpoint; his countenance is large, his forehead high, his nose aquiline, and his general expression indicative both of firmness and penetration; he bears himself with easy dignity, without the smallest approach to hauteur or reserve, and, for a Turk, is remarkably social and communicative; and his dress is usually plain, the only expense which he indulges in matters connected with personal decoration being lavished upon his arms, which are richly studded with diamonds. In a word, his appearance and demeanour immediately impress strangers with a conviction that he is no ordinary man; whilst his eager and inquisitive curiosity, continually on the alert in quest of information, shows that he has not only appreciated the importance of knowledge generally, but learned that it is the only solid basis of power. The following anecdotes of this remarkable person have been collected by Dr Russell, from the works of recent Egyptian travellers.

"'On our arrival being announced,' says Dr Richardson, 'we were immediately ushered into his presence, and found him sitting on the corner of the divan, surrounded by his officers and men, who were standing at a respectful distance. He received us sitting, but in the most gracious manner, and placed the Earl of Belmore and Mr Salt upon his left hand, and his lordship's two sons and myself at the top of the room on his right. The interpreter stood, as well as the officers and soldiers, who remained in the room during the whole time of the visit. He began the conversation by welcoming us to Cairo, and prayed that God might preserve us, and grant us prosperity. He then inquired of the noble traveller how long he had been from England, and what was the object of his journey to Egypt; to all which he received satisfactory answers. His highness next adverted to the prospect before him—the Nile, the grain-covered fields, the pyramids of Djizeh, the bright sun, and the cloudless sky—and remarked, with a certain triumphant humour on his lip, that England offered no such prospect to the eye of the spectator.' He was told that the scenery of England was very fine. '"How can that be," he shortly rejoined, "seeing you are steeped in rain and fog three quarters of the year?" He next turned the conversation to Mr Leslie's elegant experiment of freezing water in the vacuum of an air-pump; which he had never seen, but admired prodigiously in description, and seemed to anticipate with great satisfaction a glass of lemonade and iced water for himself and friends, as the happiest result of the discovery. Talking of his lordship's intended voyage up the Nile, he politely offered to render every possible facility; cautioning him at the same time to keep a sharp look-out when among the Arabs, who, he believed, would not take any thing from him or his party by violence, but would certainly steal if they found an opportunity of doing it without the risk of detection. He then related a number of anecdotes touching the petty larcenies of that most thievish race; some of which were by no means without contrivance or dexterity. But the one which seemed to amuse both himself and his friends the most, was that of a traveller, who, when eating his dinner, laid down his spoon to reach for a piece of bread, and by the time he brought back his hand believed to cherish schemes of ambition still more gigantic than any which his past career has disclosed. The caliphate and an Arabian empire have, it is thought, long floated before his wishful eye; and there can be little doubt that, in the event of a new rupture with Turkey, Bagdad and the holy cities would be irrecoverably lost to the Porte, and restored to the successors of the Saracens. Wherever the Arabic language is understood, the power of Egypt seems destined to prevail.[1] But our business here is not with speculation, but facts.

---

the spoon was away; the knife and fork soon shared the same fate; and the unfortunate stranger was at length reduced to the sad necessity of tearing his meat, and lifting it with his fingers and thumb, like the Arabs themselves. Many persons were near, but no one saw the theft committed; and all search for the recovery of the property was in vain. We now took leave of the viceroy, leaving him in the greatest good humour; he said we might go everywhere, and see every thing we wished, and that he hoped to have the pleasure of seeing us again.' In reference to the freezing experiment, we may mention, that Mehemmed Ali, very soon after the visit now described, obtained from England, through Mr Salt, the requisite apparatus. The machine on its arrival was conveyed to his palace, and some Nile water was procured for the purpose. He hung over the whole operation with intense curiosity; and when, after several disappointments, a piece of real ice was produced, he took it eagerly in his hand, and danced round the room for joy like a child, and then ran into the harem to show it to his wives.

"No one has attempted to conceal that there is in the temper of Mehemmed Ali, intermingled with many good qualities, a deep tincture of barbarism and fierceness. Impatient of opposition, and even of delay, he occasionally gives himself up to the most violent bursts of passion; and in such moments there is hardly any cruelty which he will not perpetrate or command. For instance, some time ago he had ordered that the dollar should pass for a fixed number of piasters, and it was mentioned in his presence that the rate was not strictly followed. His highness expressed some doubt of the fact, when the head interpreter carelessly observed that a Jew broker, whom he named, had a few days before exchanged dollars for him at the rate asserted. 'Let him be hanged immediately,' exclaimed the pasha! The interpreter, an old and favourite servant, threw himself at his sovereign's feet, deprecating his own folly, and imploring pardon for the wretched culprit. But all intercession was in vain; the viceroy said his orders must not be disregarded, and the unfortunate Jew was instantly led to his death. We find proofs of a similar sally at Djidda, where he appears to have used his own hands to inflict a punishment which he thought it inexpedient to remit. Hoseyn Aga, the agent for the East India Company, resident in that town, was, says a recent traveller, a remarkably fine-looking man, displaying an air of dignity mixed with hauteur; handsomely clad, too, though the heavy folds of his muslin turban were studiously drawn over his right eye to conceal the loss of it, for Mehemmed Ali one day in a fit of rage pulled it out. Yet these men are friends—great friends just at present, and will remain so as long as it may be convenient and agreeable to both parties to consider each other in that light. But the master of Egypt is not at all times so ferocious. For example, when Mrs Lushington was at Alexandria, intelligence was brought to him that a small fort at the entrance of the harbour had been taken possession of by certain Franks, and that the Turks belonging to it had been made prisoners. Some consternation prevailed among his people; but instead of being angry, he laughed heartily, and swearing by his own eyes—his favourite oath—that they must be English sailors, he directed his interpreter to write to their captain to order his men on board ship again. Upon inquiry it proved as the pasha had anticipated; the men had landed, got drunk, and crowned their liberty by seizing on the fort, and confining the unfortunate Turks, who, indolently smoking their pipes, never could have anticipated such an attack in time of profound peace. He evinced equal self-command, and still more magnanimity, when he first heard of the event which destroyed his infant navy and humbled his power. We allude to the battle of Navarino. He had not finished the perusal of the unwelcome dispatches, when he desired a European consul to assure his countrymen and all the other Franks that they should not be molested, and that they might pursue their wonted occupations in perfect security. Among the ships lying in the harbour was the wreck of one of the pasha's own vessels. The captain had committed some crime which was represented by his crew to the viceroy, who ordered him immediately on shore to answer his accusers. Conscious of guilt, he pretended sickness, till a second message from the same quarter left him no alternative; and unable longer to shun his fate, he sent all his crew ashore, and calling to an old and faithful servant, the only person on board, he bade him jump out of the port into the sea; at the same time, having loaded two pistols, he fired into the magazine, and blew up the ship and himself together. When the story was related to the pasha, he said, 'These are Frank customs; this is dying like an Englishman!'

"There is something characteristic in the following notice by Sir Frederick Henniker, who remarks, that the pasha appeared to him to have a vulgar low-born face, but a commanding intelligent eye. 'He received us in the court-yard, seated on a sofa, and wielding a pipe, dressed like a private individual, as Turks of real consequence generally are, excepting on gala days. The vice-consul and myself sat down on the sofa with him. Pipes are not offered except to equals; coffee served up,—no sugar, even though the pasha himself has a manufactory of that article,—the attendants ordered to withdraw; no pride, no affectation, even though the pasha is an upstart. Remained nearly an hour discoursing on English horses, military force, the emerald-mines at Cossier, his son's victory over the Wahabis, and his expected triumphal entry.'—It is generally stated, that since Mehemmed Ali has felt himself secure in the pashalik he has ceased to be cruel. Seldom now does he take away life, and never with torture; and if his subordinate officers were as well disposed as himself, the people, notwithstanding the oppressive taxes, would feel their property more secure. One instance of his prompt justice excited much astonishment; although a slower and more regular method would not, it is probable, in a nation so completely disorganized, have produced an equal effect. A kiachief who had not been long accustomed to the government of the viceroy punished one of his own servants with death. He was called before Mehemmed, who asked him by what authority he had committed this outrage. He thought it enough to urge in his defence that the man was his own servant. True, retorted the pasha, but he was my subject; and, in the same breath, passed sentence that the culprit should be immediately beheaded,—an effectual warning to the rest of the grandees present. This act of severity has saved the lives of many of the Arabs, who, in former times, were sacrificed by their Turkish masters on the most trifling pretences. In short, Mehemmed is well spoken of by most European travellers, though in general they estimate his character by too high a standard—the principles and habits of their own countries. There is only one author whose impression was rather unfavourable: 'I sat in the divan,' says he, 'with my eyes fixed on him; I wanted to examine the countenance of a man who had realized in our day one of those scenes in history which, when we have perused it, always compels us to lay down the book and recover ourselves. There he sat—a quick eye, features common, nose bad, a grizzled beard, looking much more than fifty, and having the worn complexion of that period of life. They tell you he is not sanguinary; men grow tired of shedding blood as well as of other pleasures; but if the cutting off a head would drop gold into his coffers, he would not be slow to give the signal. His laugh has nothing in it of nature; how can it have? I hear it now—a hard, sharp laugh, such as that with which strong heartless men would divide booty torn from the feeble. I leave him to his admirers.'—'In the usages of the table,' says Mr Carne, 'he is still an Osmanlee; knives, forks, and other useful appendages, never make their appearance at his meals. About five years ago some English travellers were graciously received by him, and pressingly invited to dine. But not even in compliance with the taste of his guests would he depart from his own habits; for, wishing to show a noble lady particular attention, he took a large piece of meat in his hand, and politely placed it before her. Perfectly dismayed at the compliment, and the sight of the savoury morsel which rested on her plate, she turned to her companion, who was more used to oriental manners, and earnestly asked what she was to do. "Eat it to be sure," was the reply. She looked at the pasha; his fine dark eye seemed to rest on her with a most kind and complacent expression; and there was no help for it but to follow the excellent advice given her by her more experienced friend.'" (*View of Ancient and Modern Egypt*, p. 358, et seqq.)

[1] *Edinburgh Review*, vol. lix. p. 124, et seqq. We have great pleasure in acknowledging that, for the leading features of the character of Mehemmed Ali, as above delineated, we have been indebted to a very able article in this journal on the state and relations of the Turkish empire. We have merely filled up, as it were, the masterly sketch drawn by the reviewer.

SECTION III.

PHYSICAL GEOGRAPHY OF EGYPT.

General description and physical conformation of the country.—Its divisions.—Is Egypt the gift of the Nile?—Opinions of Savary, Bruce, Shaw, Volney, and others on this subject.—Various depth of the alluvial soil.—Attempts to ascertain the mean rate of the deposition of mud or sediment by the river.—Speculations of the French philosophers.—Supposed difference of level, and conclusions thence deduced as to the comparative antiquity of existing monuments.—The Nile.—Its branches.—Supposed position of the source of the Bahr-el-Abiad, or true Nile.—Its alleged communication with the Niger.—Course of the river.—The Cataracts or Rapids.—Nature of these.—Physical aspect of the country.—The mouths, ancient and modern, of the river.—Its navigation.—The soil.—Lakes and canals.—The periodical inundation of the Nile.—Cause of this phenomenon.—Modes in which the waters of the inundation are distributed for the purposes of irrigation.—Air and climate of Egypt.—Etesian Winds.—Hot Winds.—The Khamsim of Egypt, the Samiel of Arabia, and the Simoom of the Desert.—Interesting particulars connected with these winds given by Volney and Bruce.—Diseases.—Plague.—Ophthalmia.—Hydrocele.—Cutaneous distempers.—Malignant Fevers.—Treatment.—Geological structure and characteristics of Egypt.

Egypt occupies the north-eastern portion of Africa, and is bounded on the north by the Mediterranean, on the east by the Red Sea, on the south by Nubia, and on the west by the deserts of Libya. Its physical configuration has been generally described at the commencement of this article. "Pour se peindre en deux mots l'Egypte," says Volney, "que l'on se représente, d'un côté une mer étroite et des rochers, de l'autre d'immenses plaines de sable, et au milieu un fleuve coulant dans un vallée longue de cent cinquantes lieues, large de trois à sept, lequel, parvenu à trente lieues de la mer, se divise en deux branches, donc les rameaux s'égarent sur un terrain libre d'obstacles, et presque sans pente."

Egypt is divided into Upper, Middle, and Lower. Upper Egypt extends from Nubia to the province of Cairo; Middle Egypt comprehends the province of Cairo, and the lateral provinces; and all the country included between the territory of Cairo, the Mediterranean, the isthmus of Suez, and Libya, forms Lower Egypt. Upper Egypt is only a long narrow valley, confined between two chains of mountains running from north to south, which commence at the last cataract of the Nile, and on reaching Cairo separate to the right and left as if to enable the Nile to extend its arms; the eastern chain taking the direction of Mount Colzum, and the western terminating in some sand hills near Alexandria. The former terminates on the borders of the valley by an escarpment, which in some places has the appearance of a very elevated wall or rampart, intersected at intervals by ravines; whilst the latter generally terminates in a gentle slope, excepting at the elbow formed by the Nile in the direction Kenneh, where it becomes more precipitous towards Siout.

The mountains which form the boundaries of this valley are the more deserving of attention, because from them, under the Pharaohs, the Ptolemies, and the Antonines, were obtained the materials not only for those stupendous monuments, which, even in their state of ruins, still make Egypt a land of wonders, but also for many of the public buildings of Italy, the remains of which attest alike the munificence of the Roman emperors, and the genius of the Roman artists. Beyond these mountains are deserts bounded by the Red Sea on the east, and by other parts of Africa on the west.

Four leagues from the Nile, and opposite Cairo, these mountains are only a ridge of rocks of about forty or fifty feet in height, dividing Egypt from the plains of Libya; and this ridge accompanies the course of the river, at a greater or less distance, like embankments intended to confine the general inundation.

Lower Egypt, comprehending all the country from Cairo to the sea, forms a triangle nearly equilateral, at least if it be reduced to the space included between the two arms of the Nile, which discharge themselves into the sea, the one at Rosetta and the other at Damietta. The base of this triangle is estimated at about seventy leagues. The name of Delta, which the Greeks gave to this part of Egypt, was applied on account of its resemblance in point of form to the fourth letter of their alphabet.

With respect to the formation of the Delta, it has been the opinion of many, even in very ancient times, that it was produced by the mud brought down by the inundations of the Nile; and this notion was adopted by Savary, who argues strenuously in support of it. In those early ages in which history has fixed no epoch, a certain people, according to him, descended from the mountains near the Cataracts, into the valley overflowed by the Nile, which was then an uninhabitable morass overgrown with reeds and canes. In what manner, or from what motive, these people were induced to descend from their ancient habitations to take up their residence amidst bogs, or how they found means to penetrate into a morass which is described as impenetrable, we are not informed, neither is it to our present purpose to inquire. At that time, however, the sea, it seems, washed the base of those mountains where the Pyramids were afterwards built, and advanced far into Libya. It covered also part of the isthmus of Suez, and the whole of what is now called the Delta formed a great gulf. But after many ages the Egyptians, by what means is not stated, formed canals to carry off the stagnant waters of the Nile; opposed strong embankments to check its periodical inundations; and, tired of dwelling in the caverns of rocks, built towns and cities upon spots elevated either by nature or art. Already the river was confined within its bounds, the habitations of men were placed out of the reach of its inundations, and experience had taught the people to foresee and announce them, when one of the kings of Egypt undertook to alter the course of the river. After running a hundred and fifty leagues between the barriers already described, the river, meeting with an insurmountable obstacle to the right, turned suddenly to the left, and, taking its course to the southward of Memphis, spread its waters throughout the sands of Libya. But the prince here spoken of caused a new bed to be dug for it to the eastward of Memphis, and, by means of a large dyke, obliged it to return between the mountains, and discharge itself into the gulf which bathes the rock on which the castle of Cairo is built. The ancient bed of the river was still to be seen in the time of Herodotus, and may even, it is alleged, be traced at this day across the deserts, passing to the westward of the natron lakes. To the herculean labours of this nameless monarch, Egypt, according to Savary, is indebted for the Delta. A regurgitation of the sea being occasioned by the enormous weight of the waters of the Nile, which precipitated themselves into the bottom of the gulf, the sands and mud carried along with them were collected into heaps; and thus the Delta, at first inconsiderable, arose out of the sea, from whose domain it was, so to speak, conquered. In short, it was a gift of the river, and it has since been defended from the attacks of the ocean by raising embankments along its base. Five hundred years before the Trojan war, the Delta was, according to Herodotus, in its infancy, eight cubits of water being then sufficient to overflow it. Strabo informs us that boats passed over it from one extremity to the other; and that its towns, built upon artificial eminences, resembled the islands of the Ægean Sea. At the time when Herodotus visited this country, fifteen cubits were necessary to cover all Lower Egypt; but the Nile then overflowed the country for the space of two days' journey to the right and left of the island, or Delta strictly so called. Under the Roman empire sixteen cubits produced the same effect; when the Arabs got possession of the country seventeen cubits were requisite; and at this day eighteen are necessary to produce a plentiful crop. Sometimes, however, the Nile rises to the height of twenty-two cubits; and the cause of this phenomenon is the accumulation of mud. Thus, in the space of rather more than three thousand two hundred years, the Delta, according to Savary, was elevated fourteen cubits.

It is natural to imagine, he adds, that the Delta has increased in length as well as in elevation. Under the reign of Psammeticus, the Milesians, with thirty vessels, landed at the mouth of the Bolbitinic branch of the Nile, now that of Rosetta, where they fortified themselves, and built a town called *Metelis*, which, in the Coptic vocabularies, has preserved the name of Messil. But this town, formerly a sea-port, is now nine leagues distant from the sea; and to this extent the Delta, according to him, has increased in length from the time of Psammeticus to the present day. Homer, in his Odyssey, makes Menelaus state, that in the stormy sea which washes Egypt there is an island called Pharos, the distance of which from the shore is such that a vessel with a fair wind may make the passage in a day. But from the manner in which he speaks of the Delta in other places, we may suppose that the island of Pharos, in his time, was not less than twenty leagues distant from the Egyptian coast, though it now forms part of the harbour of Alexandria. Great rivers occasion prodigious changes on the surface of the globe; sometimes elevating, at their mouths, islands which in time become portions of the continent. It is thus, according to Savary, that the Nile has formed almost all Lower Egypt, and created out of the waters the Delta, forming an equilateral triangle whose base is about seventy leagues; it is thus that the Meander, constantly repelling the waves of the Mediterranean, and gradually filling up the gulf into which it falls, has placed in the middle of the land the town of Miletus, formerly a celebrated harbour; it is thus that the Tigris and the Euphrates, descending from the Armenian hills, and sweeping with them in their course the sands of Mesopotamia, are imperceptibly filling up the Persian gulf.

Such are the reasons assigned by Savary for the opinion that the greater part of Lower Egypt had been produced by the operation of the Nile. But his theory has been strenuously contested by other travellers, particularly by Bruce, who has discussed the subject at considerable length. He begins by observing, that as the upper country of Egypt is merely a valley bounded by rugged mountains, it may hence seem natural to imagine that the Nile, overflowing the lower part, would be more ready to wash away the soil than add to it. It is stated by Dr Shaw, and confirmed by Bruce, that there is a gentle slope from the middle of the valley towards the foot of the mountains on either side, so that the middle, in which is the channel of the Nile, is really higher than any other portion of the valley. Large trenches are cut across the country from the channel of the river, and at right angles with its bed or channel, as far as the base of the mountains. As the river swells the canals become filled with water, which, descending to the base of the mountains, runs out at the farther extremity, and overflows the adjacent level country. When the water, having attained the lowest ground, begins to stagnate, it does not acquire any motion, by reason of the canals being at right angles with the channel of the Nile, unless in the case of excessive rains in Ethiopia, when the water by its regurgitation again joins the stream. In this case the motion of the current is communicated to the whole mass of waters, and every thing is swept away by them into the sea. It has been asserted that there was a necessity for measuring the height of the inundation, on account of the quantity of mud brought down annually by the waters, by which the landmarks were so covered that the proprietors could not distinguish their grounds after the river had subsided. But whatever might be the reason of this covering of the landmarks in ancient times, it is certain that the mud left by the Nile could not be the cause in the time of Herodotus, or during any period of time mentioned by that historian. He assigns only one foot of increase of soil throughout Egypt in a hundred years, from the mud left by the river; and the increase during one year, therefore, being only the hundredth part of a foot, could not possibly cover any landmark whatever. Besides, the Egyptian lands are at this day separated by huge blocks of granite, which frequently have gigantic heads; and these, at the rate mentioned by Herodotus, could not be covered in several thousand years. Besides, the Nile does not now bring down any great quantity of mud. Throughout Abyssinia, the channel of every torrent has been worn to the bare rock, and almost every rivulet runs in a hard stony bed, all the loose earth being long ago washed away; so that an annual and equable increase of the earth from the sediment or deposit of the waters is impossible. Bruce made a great number of trials of the water of the Nile during the time of its inundation, in different places. At Basboch, when just leaving the cultivated parts of Abyssinia, and about to enter Sennaar, the sediment was composed of fat earth and sand, and its quantity was exceedingly small. At the junction of the Nile and Astaboras the quantity of sediment was very little augmented; it consisted still of the same materials, though sand predominated in its composition. At Syene the quantity of sediment was almost nine times greater than before; but it was now composed almost entirely of sand, with a very small quantity of black earth. He also made a similar experiment at Rosetta, which however was not so often repeated as the others; but the result of the whole was, that in the strength of the inundation the sediment consisted mostly of sand, and, towards the end, it was in a great measure composed of earth. Had the Nile brought down the quantities of mud which it has been said to do, it ought to have been most charged with it at Syene, as there it contained the whole that was to be conveyed by it into Egypt. Instead of this, however, the principal part of the sediment at this place consisted of sand; which is accounted for from the vast quantities raised by the winds in the deserts between Gooz and Syene, and swept along the descending valley of the Nile towards Middle and Lower Egypt.

Bruce further adopts and argues in favour of the opinion that there has been a continual decrease of water since the creation of the world. In this case, therefore, if the land of Egypt had been continually increasing in height, whilst the water which was to cover it decreased, there must have been frequent famines on account of the want of a sufficient inundation. But so far is this from being the case, that, according to the testimony of several Arabian manuscripts, there had not, when Bruce was in Egypt, been one scarce season from the lowness of the inundation for thirty-four years, though during the same space famine had been three times experienced in consequence of too great an abundance of water. If there had been such an increase of land as Herodotus and others suppose, it must now have been very perceptible in some of the most ancient public monuments. This, however, is by no means the case. The base of every obelisk in Upper Egypt is to this day quite visible, excepting where covered by drift-sand. Near Thebes there are still extant two colossal statues, plainly designed as nilometers, and which ought by this time to have been almost covered with earth; but, notwithstanding the length of time these monuments have remained there, they are still bare to the very base.

The strongest argument which the advocates for the increase of land in Egypt make use of is, that the measures by which the quantity of inundation is determined are smaller now than they were in former times; and these small measures are said to have been first introduced by the Saracens. But, as Bruce observes, such an expedient could not have answered any good purpose, as no decrease of the measure could have augmented the quantity of corn produced by the ground. Savary admits that, to render his calculation concerning the increase of land in Egypt absolutely exact, it would be necessary to determine the precise length of the Greek, Roman, and Arabian cubit, and even to know the different alterations which that measure had undergone among the nations who employed them; but this nicety he considers as unnecessary, regarding the general fact to be fully established by what he had said before. Bruce, however, has treated the subject with much greater accuracy. From the situation of Canopus, the distance between Egypt and Cyprus, and the extension of the land to the northward, he concludes that no addition of any consequence can have been made to it for three thousand years past. The only argument left for the increase of land, therefore, must be derived from the nilometer. The use of this instrument was to determine the quantity of the inundation. The first step was to ascertain what space of ground was overflowed in a given number of years; and this being determined by mensuration, the next point was to determine the produce of the ground upon an average. Having thus become acquainted with the greatest and least crops produced, together with the exact extent of ground overflowed, they were furnished with all the necessary principles for constructing a nilometer; and nothing now remained but to erect a pillar in a proper place, and divide it exactly into cubits. This was accordingly done; the pillar was first divided into cubits, and these again were subdivided into digits. The first division of this kind was undoubtedly that mentioned in Scripture, and called the cubit of a man, being the length of the arm from the middle of the round bone in the elbow to the point of the middle finger; a measure still in use among all rude nations. But as no standard could be found by which this measure might be exactly determined, authors have differed very much concerning the true length of the cubit when reduced to our feet and inches. Dr Arbuthnot reckons two cubits mentioned in Scripture, the first containing one foot nine inches and $\frac{888}{1000}$ths of an inch, and the second one foot and $\frac{824}{1000}$ths of a foot; but Bruce is of opinion that both these estimates are too large. He found, by mensuration, that the Egyptian cubit was exactly one foot five inches and three fifths of an inch; and Herodotus mentions that in his time the cubit used for determining the increase of the Nile was the Samian cubit, containing about eighteen of our inches. The latter also informs us, that, in the time of Mœris, the minimum increase of the inundation was eight cubits, at which time all Egypt below the city of Memphis was overflowed; but that in his own time sixteen, or at least fifteen cubits, were necessary to produce the same effect. But to this account Bruce objects, that Herodotus could have no certain information concerning the nilometer, because the priests, who alone had access to it, refused to tell him anything of the matter. Herodotus also states, that in the time of Mœris a great lake was excavated in order to carry off the waters of the inundation; and this superfluous quantity Bruce supposes to have been conveyed into the desert for the use of the Arabs, whilst by such a vast drain the rise of the water on the nilometer would undoubtedly be diminished. But even granting that there was such a difference between the rise of the water in the time of Mœris and in that of Herodotus, it does not appear that any thing like it has ever since occurred. Strabo, who travelled into Egypt four hundred years after the time of Herodotus, found that eight cubits were then the minimum, as well as in the time of Mœris. From some passages in Strabo, however, it appears that it required a particular exertion of industry to cause this quantity of water to produce a plentiful crop; but there is not the least reason to suppose that the very same industry was not necessary in the time of Mœris; and hence it cannot be maintained that any increase of land is indicated by the nilometer. About a hundred years afterwards, when the Emperor Hadrian visited Egypt, we learn from unquestionable authority that sixteen cubits were the minimum when the people were able to pay their tribute; and that in the fourth century, under the Emperor Julian, fifteen cubits were the standard of contributions. Both of these accounts correspond with that of Herodotus. But Procopius, who lived in the time of Justinian, informs us that eighteen cubits were then requisite as a minimum.

From these accounts, so various and so discordant, it is obvious that no certain conclusion can be drawn. It is not easy indeed to determine the reason of this difference in point of fact. The only conjecture which can be offered is, that as it appears a smaller quantity of water will, by proper management, answer the purpose of producing a plentiful crop, so it is not unreasonable to suppose that at different periods the industry of the people has varied so much as to occasion the difference in question. This would undoubtedly depend very much upon the governor for the time; and indeed Strabo informs us that it was by the great care of the governor Petronius that such a small quantity of water was made to answer the purpose. From the whole of the above statements, however, it is probable that no increase of land was indicated by the nilometer from the time of Mœris to that of the Emperor Justinian. On the conquest of Egypt by the Saracens, their barbarous and stupid caliph destroyed the nilometer, causing another to be built in its stead; and afterwards fixed the standard of paying tribute considerably below what it had usually been. The Egyptians were thus kept in continual terror, and constantly watched the new nilometer, to observe the gradual increase or decrease of the inundation. On this he ordered the new nilometer to be destroyed, and another to be constructed, and all access to it to be denied to the people; a prohibition which was continued to Christians until the time of the present viceroy. From his own observations, however, Mr Bruce concludes that fifteen cubits are now the minimum of the inundation; and as this coincides with the accounts given in the times of Herodotus and Hadrian, he infers that, from the earliest ages to the present time, the same quantity of water has been necessary to overflow this country.

With respect to what has been urged by Savary concerning the former distance of the island of Pharos from the mainland to which it is now joined, and also regarding the city of Metelis having been once a sea-port, Volney proves that he has quoted Strabo unfairly, and consequently that no stress whatever should be laid upon a garbled authority. The principal, indeed the only evidence, which remains, therefore, is the passage already quoted from Homer, in which it is stated that the island of Pharos was as far distant from one of the mouths of the Nile as a vessel could sail in one day before the wind. But it is to be observed that, when Homer speaks of the distance of this island, he does not mean its distance from the shore opposite, as Savary has translated him, but from the river Nile; and, further, that by a day's sail we must not understand the indefinite distance which the vessels, or rather boats, of the ancient Greeks, could navigate in a day, but an accurate and determinate measure of five hundred and forty stadia. This measure has been ascertained by Herodotus, and is the precise distance between Pharos and the Nile, allowing, with M. d'Anville, twenty-seven thousand toises to five hundred and forty stadia. It is therefore far from being proved that the increase of the Delta or of the continent was so rapid or extensive as has been represented; and, if such an opinion were maintained, it would still be impossible to explain how the land at this point, which has not gained half a league since the days of Alexander, should have gained eleven in the much shorter period which elapsed from the time of Menelaus to that of the Macedonian conqueror. The utmost extent of the encroachment of the land upon the sea, however, may be learned from the words of Herodotus; who informs us, that the breadth of Egypt, along the sea-coast, from the Gulf of Plinthine to the Lake Serbonis near Mount Casius, is three thousand six hundred stadia, and its length from the sea to Heliopolis fifteen hundred stadia. For, allowing the stadium of Herodotus to have been equal to between fifty and fifty-one French toises, it follows that the fifteen hundred stadia just mentioned are equal to seventy-six thousand toises; which, at the rate of fifty-seven thousand to a degree, gives one degree and nearly twenty minutes and a half. But, from the astronomical observations of Niebuhr, the difference of latitude between Heliopolis and the sea is one degree twenty-nine minutes at Damietta, and one degree twenty-four minutes at Rosetta; and hence, supposing the measures of the historian and the observations of the traveller to be both accurate, there is a difference of three minutes and a half, or a league and a half of encroachment on the one side, and eight minutes and a half, or three leagues and a half, on the other.

The doctrine, therefore, that Egypt is absolutely the gift of the Nile, a doctrine which was originally proposed by Herodotus, appears to be wholly untenable. From the facts above stated, indeed, we may conclude, first, that the apparent augmentation of the land, arising from the encroachment of the river on the sea, has, in a long tract of ages, been exceedingly trifling; and, secondly, that even this superficial increase may be in a great measure, if not altogether, attributed to errors arising from the comparison of the ancient with the modern standards of measurement. But although the surface of Egypt may have undergone little change in point of extent, from the supposed encroachments of the river, there can be little doubt whatever that the alluvial deposits made by the Nile during its periodical inundations must, in the course of ages, have become considerable. Accordingly, the men of science who accompanied the French expedition to Egypt undertook to measure the depth of alluvial matter actually deposited; and, proceeding on the data thus obtained, they attempted to deduce the mean rate of accumulation, and thence to form conjectures respecting the comparative antiquity of a number of the monuments situated on the banks of the river. By sinking pits at different distances, and in a variety of places, both on the margin of the stream and on the outer edge of the stratum of alluvial matter, they ascertained that the surface of the soil slopes downward from the banks of the river to the base of the hills on either side; that the thickness or depth of the deposit is generally about ten feet near the current, but decreases gradually in proportion as it recedes from the stream; and that beneath the mud there is a bed of sand, analogous to that of the adjoining deserts, on which the alluvial deposit is, as it were, superimposed. Thus the surface of the valley has acquired a convex form, similar to that observed in the plains which border on the Mississippi, the Ganges, and other great rivers, where the alluvial deposits are generally most considerable on the margin of the currents. This being the case, then, the next step was to ascertain the mean rate of accumulation or deposition of alluvial matter in a given period of time, in order thence to form a sort of chronometrical scale, by which the age in which any monument or work of art in the immediate neighbourhood of the river had been erected might be determined by approximation. Assuming that in the original erection of monuments, whether temples, palaces, or statues, the men by whom they were constructed would not place their foundations or bases below the level of the river at ordinary or average inundation, and adopting as the standard of comparison the received chronology of the world, it is obvious that, from the total depth of the alluvial deposit, the mean secular accumulation would be at once obtained, and that this, again, would give the number of ages which had elapsed since any monument situated as we have already described had been founded.

But there is another mode of arriving at the same or similar results. We learn from Herodotus, that unless the river rose fifteen or sixteen cubits, it did not overflow its banks, and no contributions were levied; and under the Arabs sixteen cubits was the lowest elevation which would allow of an assessment. But the accumulation of soil has raised the standard; and unless the water rise considerably higher, there is now no chance of an abundant harvest. In 1779, which was a bad year, the water rose at the mikyas or nilometer, sixteen cubits and two inches; but in 1800 it reached eighteen cubits three inches. Now, supposing this height to be exactly equivalent to the standard of sixteen cubits at the time the mikyas was erected (A. D. 847), the difference between the two numbers (two cubits and three inches) will give the increase of elevation in the bed of the river since the year 847; so that we have 1·49 metres, or 3·77 feet, as the numerical expression for the accumulation of soil in about nine centuries and a half, or nearly four inches in a century. Again, at Elephantine near the southern extremity of Egypt, the ancient nilometer mentioned by Strabo is still standing, and the highest measure marked upon its scale is twenty-four cubits; but the water, when at its greatest elevation, now rises 2·413 metres, or nearly eight feet, above that mark, whilst, as appears from an inscription on the wall, it rose only 0·31 of a metre, or 1·01 foot, above the same point at the commencement of the third century of our era. The difference, then, between these numbers (2·11 metres, or 6·9 feet), gives the accumulation of soil in the bed of the river, at that place, during sixteen hundred years, that is, supposing no increase to have taken place in the absolute quantity of water in the river; and from this it follows that the secular or centenary accumulation amounts to 0·132 of a metre, 0·434 of a foot, or rather more than five inches. The approximation of the results thus obtained from independent data affords a very strong presumption in favour of their accuracy; and we shall probably come very near the truth in assuming the mean of both, or four inches and a half, as the average secular accumulation. Among the dates thus ascertained, we shall now proceed to mention some of the most remarkable.

And, first, the depth of the soil around the colossal statue of Memnon at Thebes gives only 0·106 of a metre, or rather less than four inches, as the rate of secular accumulation, whilst the mean of several observations made in the valley of Lower Egypt gives 0·126 of a metre, or rather more than four inches. But the basis of the statue of Memnon, having been placed on an artificial mound, must have been originally raised above the level of the inundation; and, from excavations made near it, the French ascertained that the original height of the terrace was six metres, or 19·686 feet, above the level of the soil. A similar result was obtained from examining the foundations of the palace at Luxor;[1] and, in both cases, no doubt remained that the foundations of these edifices were above the level of the river at ordinary or average inundations. Taking 0·126 of a metre, therefore, as the mean secular accumulation of alluvion, the depth of the soil round the statue of Memnon, divided by this quantity, gave 4760 as the number of years which had elapsed since the monument in question had been erected, or 2960 years before Christ. But, according to the system of chronology founded on the Samaritan text and the Septuagint version of the Scriptures, the deluge occurred in the year 3716 before Christ; and, therefore, according to the above calculation, and proceeding on the data we have mentioned, the erection of this colossal statue took place 756 years after the flood, which is also the approximate date of the foundation of Thebes.[2] Again, the alluvial deposit collected around the base of the obelisk of Luxor indicates, in the same way, that it was erected about fourteen centuries before the Christian era. Thirdly, the causeway which traverses the plain of Siout, or Lycopolis, furnishes similar data for concluding that it was founded nearly twelve hundred years anterior to the same epoch. Lastly, the pillar or obelisk at Heliopolis, six miles from Cairo, appears, from the same sort of evidence, to have been raised about the period last mentioned; but as the waters of the inundation recede more slowly on the plain of the Delta than in the valley of Upper Egypt, the accumulation of alluvial soil will consequently be more rapid there than higher up the stream, and hence the foundations of edifices and monuments will be at a proportionally greater depth than those of the same antiquity in the middle and upper provinces.[3]

It is obvious, however, that no great reliance can be placed on such calculations as those of which we have here endeavoured to give some account, and that several elements of error enter into the premises from which they have been deduced. In the first place, the experiments made by the French to ascertain the depth of the alluvial soil were too few in number, and too hastily performed, to render it safe to adopt the results obtained as the basis of reasoning. Secondly, the deposition of mud or soil in the valley of Egypt must have proceeded more rapidly in ancient times than it does in the present day, when all the rocks over which the Nile and its tributaries now flow have long been washed bare, or even than it has done ever since its effects first became an object of inquiry and examination. Thirdly, it is impossible to ascertain whether the measures referred to by the ancient historians were always of the same standard, or whether, in fact, there was any fixed standard at all. And, lastly, the variations in the different systems of chronology are, independently of all other considerations, a double source of uncertainty in such calculations as those which we have been considering. In fact, the very thing to be proved is in some measure taken for granted, and the assumption contained in the premises is merely reproduced in the conclusion. At the same time, in as far as any value may be attached to the dates thus ascertained, they unquestionably serve to negative the extravagant chronology of the ancient Egyptians, and to reduce it within those limits which history, both sacred and profane, has assigned to the early civilization which took root on the banks of the Nile. Further, it is manifest that, though the level of the land has been raised, its superficial extent towards the sea has not been materially increased, and that there appears to be but little ground for the apprehension expressed by Dr Shaw, that in process of time the whole country will be raised to such a height as to prevent the river from overflowing its banks, and that Egypt, deprived of the annual inundation, will, from being the most fertile, become one of the most barren parts of the universe.[4] "As the formation of land in the Delta," says Dr Russell, "proceeds at a quicker rate than in the higher parts of the basin, the issue of water into the sea becomes year after year less rapid, and consequently less copious; the current is retarded by the accumulation of mud; the mouths are successively choked by the increasing masses of sand and soil; and hence, in the course of ages, the stream, creating a barrier against its own escape, will be thrown back upon the more elevated portion of the valley, and become the willing servant of the agriculturists from Rosetta to the Cataracts."[5]

The soil of Lower Egypt is so horizontal and so equal, that at the moment when, on approaching it from the sea, the date trees are discovered in the horizon, the mariner is still about twenty miles distant from the coast; and if he penetrates the country by one of the branches of the Nile, he ascends by so gentle an inclination that he cannot advance more than a league in the hour. The aspects of the plain vary but little. These are, palm trees, isolated or in clusters, which become fewer as you advance; villages built of earth, and having an air of ruins; a surface without apparent limits, which, according to the season of the year, is a sea of fresh water, a marshy plain, an expanse of verdure, or an immense field covered with sand, over which the eye wanders fatigued by the monotony of the prospect. In advancing towards the apex of the Delta, or the point where the bifurcation of the Nile takes place, there are discovered towards the west three isolated masses, which from their forms are immediately recognized as the Pyramids. A little further on commences the valley of the Nile, which is prolonged towards the south, between two chains of heights nearly parallel, for about a hundred and fifty leagues. By its extent, its arid aspect, and its sterility, the eastern bank of the river justifies the denomination of desert which it has received; whilst the western bank, which is only the crest of a rock covered with sand, presents the appearance of a mound or causeway. In short, let the reader imagine on one side a narrow sea and rocks, on the other immense plains of sand, and in the middle a river, flowing through a valley of a hundred and fifty leagues in length, and from three to seven in width, which at the distance of thirty leagues from the sea separates into two arms, the branches of which wander over a soil almost free from obstacles and void of declivity, and he will be enabled to form a tolerable idea of this singular country. At the same time, the change of the seasons communicates variety even to the narrow valley of the Nile. Towards the winter solstice vegetation appears; the verdure of the meadows delights the eye; a multitude of odoriferous shrubs perfume the air; and Egypt forms then a delicious garden. At the vernal equinox the soil, subjected to all the influence of a sky without clouds, and of continual winds, which often blow with great violence, becomes dry and dusty; whilst, at a still later period, namely, after the periodical inundation, by which it is almost entirely renovated, it is only a vast marsh.[1]

[1] This word is an European corruption of *El-Oksor* or *El-Ocsor*.

[2] According to the reckoning in the Hebrew text, the deluge occurred 2348 years before Christ; and hence, comparing the above calculation with this chronological estimate, the celebrated metropolis of the Thebaid was founded 612 (2960—2348) years before the flood. Klaproth, however, has shown that, in this matter, a preference ought to be given to the Samaritan text, or even to the Septuagint version, inasmuch as a singular approximation to the former is obtained by taking a mean between it and the Hindu and Chinese epochs. (*Asia Polyglotta*, 25, 29.)

[3] *Encyclopedia Metropolitana*, art. *Egypt*. "To form these calculations," says the able and learned writer whom we have here followed, "with such accuracy as would render them less liable to controversy, more time and observation would be requisite than could be given by the French during the short period they continued in undisturbed possession of Egypt; one general and important consequence, however, arising from their inquiries can hardly be overlooked or denied, viz. that the dates thus obtained are as remote from the extravagant chronology of the ancient Egyptians as they are consistent with the testimony of both sacred and profane history with regard to the early civilization of that country."

The Nile, which is the largest river of the old world, and may be described as the great artery of Egypt, has its true sources in a region to which the restless foot of adventure has not yet penetrated; and little more is known of them now than in those days when they excited the curiosity of Cæsar, and occupied the researches of Eratosthenes. The learned librarian of Alexandria, indeed, distinguished three principal branches of the Nile. The first or most easterly, being identical with the Tacazé of the moderns, flows down the northern side of the table-land of Abyssinia; the second known branch, or the Bahr-el-Azrek, after making a circuit or detour on the table-land of Abyssinia, descends through the plains of Sennaar; and both are tributaries of the Bahr-el-Abiad or White River, which is the true Nile, and probably has its sources in the elevated chain to the south of Darfûr, called Djibel-el-Kumri or Mountains of the Moon. The hypothesis of a connection between the Niger and the Nile has been destroyed by recent discoveries, which leave no longer any doubt that the former discharges itself into the sea by several mouths between the Bights of Benin and Biafra. Browne, indeed, has positively asserted that the rivers Misselad and Bar-koolla run from south to north; but even this fact, which is generally admitted, does not allow us to suppose any other communication between the Nile and the Niger than may be formed by canals, like those of the Cassiquiari in Guiana, winding along a table-land, where the sources of the Misselad and Bar-koolla are at a short distance from each other and from those of the Nile; or, perhaps, as it has been affirmed that travellers have passed by water from Timbuctoo to Cairo, it may be supposed that the sources of all these rivers are sufficiently near to admit of intercommunication by means of temporary lakes formed during the rainy season. But the Bahr-el-Abiad, or true Nile, whatever be its source, receives two large rivers from Abyssinia, and then turning to the southward, makes an extensive sweep through the country of Dongola. But at three different points of its course it is intersected by mountains, and at each it has forced a passage for itself through the rocky barrier. The second cataract in Nubia is the most violent and the most difficultly navigable. The third is at Syene or Assouan, the point where the Nile enters Egypt. The height of this cataract, which has been greatly exaggerated by some travellers, varies according to the season, and is generally about four or five feet. The Cataracts are in fact rapids rather than falls; and at the second, of which an admirable description has been given by Belzoni, the water rushes onward with great velocity. The ridges of rock which formerly crossed the line of the river, and gave rise to the celebrated falls the sound of which was heard at the distance of many a league, and stunned the neighbouring inhabitants, have been insensibly worn down by attrition, until the falls have disappeared, and rapids only remain.[2] From Syene to Cairo the river flows along the valley, between two mountain ridges, one of which extends to the Red Sea, and the other terminates in the deserts of Libya. The river occupies the middle of the valley as far as the strait called Djibbel-Silsili, about forty miles in length, at the mouth of which it runs along the right side of the valley, which is bounded by a steep line of rocks cut into peaks, whilst the ridge on the left is accessible by a slope of varying acclivity. The mountains which confine the basin of the Nile in Upper Egypt are intersected by defiles, which on one side lead to the shores of the Red Sea, and on the other to the Oases. Near Benisouef, the valley, already much widened on the west, presents on that side an opening, through which is obtained a view of the fertile plains of Fayoum, forming a sort of table-land, separated from the mountains on the south and west by a wide valley, a portion of which, being always laid under water, is hence called Birket-el-Karoun. Near Cairo, the chains which limit the valley diverge on both sides, whilst in front opens the vast plain of the Delta; and at Battu-el-Bahara the river separates into two branches, one flowing to Rosetta, the other to Damietta, and forming together two sides of the equilateral triangle called the Delta; which, however, was larger in former times, being bounded on the east by the Pelusiac branch, which is now choked up with sand, and on the west by the Canopic branch, which is partly confounded with the canal of Alexandria, and partly lost in Lake Etko.[3]

In ancient times the Nile discharged itself into the sea by seven different mouths or embouchures. The first of these was the *Canopic* mouth, which flowed into the sea near Canopus, a town situated 120 stadia or fifteen miles to the east of Alexandria, and corresponds with the present outlet of Lake Etko, or, according to others, with that of the Lake of Aboukir or Maadieh, through which the Nile then flowed;[4] the second was the *Bolbitic* or *Bolbitine*, from Bolbitiné, a town on its banks, near the place where Rosetta now stands; the third, the *Saïtic*, from Saïs, confounded by Strabo with Tanis, probably the opening into the present Lake Burlos; the fourth, the *Sebennytic*, from Sebennytus, the course of which is supposed to be marked by the canal of Shibin-el-koum; the fifth, the *Phatnitic*, *Pathmetic*, or *Bucolic*, which passes by Damietta, and now forms the eastern branch of the Nile; the sixth, the *Men-*

[2] "A similar effect, which time will produce on the cliffs of Niagara," says Dr Russell, "will be attended with a similar result on the chain of lakes that terminate in Erie, the contents of which will at length find their way to the ocean along the bed of the St Lawrence. In the remote ages of the future, the immense valleys now occupied by the Superior, Michigan, and those other inland seas which form so striking a feature in North America, will be covered with flocks, herds, and an agricultural population, and only watered by a fine river passing through their centre. In this way the interior of every continent is drained, while new tracts of alluvial land are added to its extremities." (*View of Ancient and Modern Egypt*, p. 43.)

[3] Malte-Brun, *Geography*, vol. iv. p. 20, Eng. transl. Girard, *Memoires sur l'Egypte*, tom. iii. p. 13.

[4] This was also called the *Heracleotic* and *Naucratic* mouth; the one from a *Heracleion* or temple of Hercules, and the other from Naucratis, a town on its banks. (See Coote's *Plan du Nouveau Canal d'Alexandrie dit Mahmoudyeh*, annexed to Mengin's *Hist. de l'Egypte.*)

desian, so named from Mendes, a town sacred to the Egyptian Pan, which is lost in Lake Menzaleh, the mouth of which is represented by that of Dibeh; and the seventh, the *Pelusiac*, which seems to be represented by what is now the most easterly mouth of Lake Menzaleh, near the spot where are still to be seen the ruins of Pelusium.[1] But the *septem ostia Nili*, or seven mouths of the Nile, are at present reduced to two, namely, the Bolbitinic and Phatnitic, or those of Rosetta and Damietta; and of the other five scarcely any distinct vestiges are now traceable, except a canal or two, which are only navigable during part of the year.

The depth and rapidity of the Nile vary according to the particular place and the season of the year. In its ordinary state, the river, from its mouth to the Cataracts, carries no vessel exceeding sixty tons burden. At Damietta it is seven or eight feet deep when the waters are low; but at Rosetta the depth does not exceed four or five feet in the same state of the river. When the waters are high, the depth at both embouchures is increased about forty-one feet, and corvettes carrying twenty-four guns can then sail up as far as Cairo. During the inundation the navigation is facilitated by means of agents which act in a contrary direction; for whilst the strength of the current carries vessels rapidly from the Cataracts to the bogaz or embouchure, the strong northerly winds, which prevail during nine months of the year, enable them with their sails set to ascend the river with almost equal rapidity. When the river is low, and the stream consequently less powerful, these winds, which are constant during the time they prevail, often render it impossible for vessels to make their way downwards even with their sails furled; and hence the practice at such times is to row down the stream during the night, when the wind has subsided, and to halt somewhere during the day; whilst, on the other hand, the vessels which are upward bound sail during the day, and come to an anchor during the night. The passage from Cairo to the Mediterranean occupies from eight to ten days; but, by means of steam navigation, it might easily be performed in less than half that time. When both voyages are practicable, it is an interesting sight to see the numerous boats impelled by opposite agents, passing one another with almost equal rapidity. The mouths of the Nile are of difficult navigation even during the high state of the river, the shifting sand-banks constantly creating unforeseen dangers. With the aid of a little address, combined with courage, the Cataracts are sometimes passed; the lowest in particular being, as above stated, a rapid rather than a fall, and the others, though more perilous, partaking of the same character.

It has already been observed, that the soil of Lower Egypt chiefly owes its existence to the deposition of mud or earth by the Nile, which has also formed the banks at the different mouths of that river. The mud of the Nile first covered the low ground nearest to its bed or channel, whilst the increase of soil from the deposition of mud was more gradual in its progress in distant parts; and hence arose the formation of lakes. But these in their turn were gradually filled up by the land formed out of the deposited mud of the river, which consequently increased the boundaries of Lower Egypt, by taking from the sea; yet as the tendency of the sea is to resist such encroachments, it is probable that the ground formed by the deposited mud of the Nile will no longer continue to increase in one direction without diminishing in another. The experience of centuries has fully evinced, that the sea has actually taken more from the extent of Egypt than has been compensated by the mud of the Nile. By the simple operation of physical causes, it may be concluded, that if nature and art do not co-operate, if the water be permitted to increase, and the channels of the different branches be augmented, the sea will continue to snatch new lands from the inhabitants; and this appears to be the inevitable doom of Egypt, unless counteracted by the labour and ingenuity of man. A large proportion of the land formerly watered by the branches of the Nile already described, is now the bed of Lake Menzaleh. Lake Bourlos, as we have seen, is not far from the mouth of what was formerly called the Sebennytic branch, and Lake Maadieh is near the mouth of the ancient Canopic arm. But Lake Mareotis was at too great a distance from the Nile to be filled up with the mud which it deposits, and its waters were diverted from the lake by a canal which had been cut for the conveyance of water to the city of Alexandria; and hence, having no communication with the sea, its waters were gradually evaporated, and it continued nearly, if not altogether dry until those of the sea were let into it by the British during the siege of Alexandria, in the manner already described. There are also a few lakes which owe their origin to the redundant waters of the Nile diffusing themselves over hollow places in which they are confined, and which only disappear by the gradual process of evaporation. In addition to the branches and chief canals already mentioned, there are numerous lesser canals in Lower Egypt which convey the waters of the inundation, whilst dykes in different districts serve to retain them. By these waters the more elevated grounds are fertilized, and then other cantons in succession, after which they are poured into the lakes, or are lost in the sea.

The cause of the fertility of Egypt is the Nile, without which, as it almost never rains in that part of the world, the whole country would soon become an uninhabitable desert. Swelled by the rains which fall in Abyssinia, the river begins to rise about the month of May; but the increase is inconsiderable till towards the end of June, when it is proclaimed by a public crier through the streets of Cairo. About this time it usually rises to the height of five or six cubits; and when it has attained sixteen, great rejoicings are made, and the people cry out that God has given them abundance. This commonly takes place about the latter end of July, or at farthest before the 20th of August; and the sooner it occurs, so much the greater are the hopes of a good crop. Sometimes, though rarely, the necessary increase does not take place till a later period of the season. In the year 1705 the river did not swell to sixteen cubits till the 19th of September; and the consequence was that the country was depopulated by famine and pestilence. In ordinary circumstances, however, the rise of the Nile commences at the summer solstice, or towards the end of June; it attains its greatest height at the autumnal equinox, or towards the end of September; it then remains stationary for several days, and at length diminishes, but at a less rapid rate than that at which it rose. But as the Nile of itself cannot overflow the whole country so as to fertilize it, there are cut from it across the country innumerable canals, by which the water is conveyed to distant places; and almost every town or village has one of these canals. In those parts of the country which the inundation does not reach, and where more water is required than it can furnish, as for irrigating of gardens, recourse is had to artificial means for raising it from the river. In former times Archimedes' screw was employed for this purpose; but it is now disused, and instead of it the Persian wheel, and other engines of more modern and approved construction, have been introduced. The rise of the inundation is measured, as has already been observed, by an instrument adapted for the purpose, and called a nilometer. This is placed between Gizeh and Cairo, on the point of an island in the middle of the river, but somewhat nearer to Gizeh. It consists of a round tower with an apartment, in the middle of which is a cistern neatly lined with marble. The bottom of this cistern reaches to that of the river, and there is a large opening by which the water has free access to the inside. The rise of the water is indicated by an octagonal column of blue and white marble, on which are marked twenty cubits of twenty-two inches each. The two lowermost of these have no subdivisions; but each of the rest is divided into twenty-four parts called digits; and the whole height of the pillar is thirty-six feet eight inches. When the river has attained its proper height, all the canals are opened, and the whole country is laid under water. During the time of the inundation a certain vertical motion of the waters takes place; but notwithstanding this, the Nile is so easily managed, that many fields lower than the surface of its waters are preserved from injury merely by a dam of moistened earth seldom more than eight or ten inches in thickness. This method is used particularly in the Delta when it is threatened with a flood.

---

[1] In the time of Herodotus, the river, it appears, divided, near the point of the Delta, into three principal arms: the Canopic (1) on the west, the Pelusiac (7) on the east, and the Sebennytic (4) in the middle; whilst from the latter there issued two smaller arms, the Saïtic (3) on the west, and the Mendesian (6) on the east. These were considered as natural channels; but the two remaining arms, namely, the Bolbitinic, between the Canopic and Saïtic, and the Bucolic, to the west of the Mendesian, were artificial.

As the Nile does not always rise to a height sufficient for the purposes of agriculture, the former sovereigns of Egypt expended great labour in cutting proper canals, and in forming lakes or reservoirs, in order to supply the deficiency. Some of these are still preserved, but until the reign of the present viceroy great numbers had been rendered useless through the indolence or barbarity of his predecessors. Those which convey the water into Cairo, the province of Fayoum, and Alexandria, were formerly most attended to by the government; but now all are equally under its superintendence, and kept in a state of good repair. A number of other canals, under the care of those who derive advantage from them, proceed from that arm of the Nile which flows past Damietta, and fertilize the province of Sharkieh, which, forming part of the isthmus of Suez, is the most considerable of Egypt, and the most capable of a great increase of cultivation. The plains of Gaza, situated beyond this province, and possessed by the Arabs, would be equally fertile were it not for the propensity of these people to destroy every thing within their reach. A number of other canals run through the Delta; and the remains of those which watered the provinces to the eastward and westward show that in former times these were the best cultivated parts of Egypt. We may also presume, from the extent of the ruins of Alexandria, the construction of the canal, and the natural level of the lands which encompass the Lake Mareotis, and extend westward to the kingdom of Barca, that this country, now almost a desert, was once sufficiently rich in productions of every kind to furnish the city of Alexandria with its whole subsistence.

The air and climate of Egypt are extremely hot, not only from the height of the sun, which in summer approaches to the zenith, but from the want of rain, and the vicinity of those burning and sandy deserts which lie to the southward. In the months of July and of August, Reaumur's thermometer stands, in the shade, at the height of twenty-four or twenty-five degrees above the freezing point; and in the southern parts it is said to rise still higher. Hence the two principal seasons to be distinguished in Egypt are the cool and the hot, or spring and summer, with a very short winter in the north. "La température de l'Egypte," says Rifaud, "varie selon la latitude et l'époque de l'année où l'on fait des observations. Dans le nord, le thermomètre descend en hiver jusqu'à deux ou trois degrés au-dessus de zéro; dans les chaleurs, il descend rarement au-dessous de 22 degrés. Dans le sud, vers Ecouan (Assouan) on a constaté des chaleurs de 34 degrés à l'ombre, et le thermomètre, placé dans le sable, marquait jusqu'à 54 degrés au soleil.[1] The summer continues during the greater part of the year, namely, from March to November, or even longer; and by the end of February the sun is intolerable to a European even at nine o'clock in the morning. During the whole of this season the air seems to be inflamed, the sky sparkles, and profuse perspiration takes place, even without the least exercise, and although covered with the lightest dress. But this heat is tempered by the inundation of the Nile, the fall of the night dews, and the subsequent evaporation; so that some of the European merchants, as well as the natives, complain of the cold in winter. The dew which we speak of is not formed regularly throughout the summer, as with us, the parched state of the country not affording a sufficient quantity of vapour for this purpose. It is first observed about the end of June, when the river has begun to rise, and consequently a greater quantity of water is converted into vapour by the heat of the sun, which being soon condensed by the cold of the night air, descends in copious dews.

It might naturally be imagined, that as, during three months in the year, Egypt is a wet and marshy plain, the excessive evaporation and the putrefaction of the stagnant waters would render it exceedingly unhealthy. But this is by no means the case. The great dryness of the air causes it to absorb vapours of all kinds with the utmost avidity; and these rising to a great height, are carried off by the winds either to the southward or northward, without having time to communicate any of their deleterious effects. This dryness is so remarkable in the internal parts of the country, that meat exposed to the open air does not putrefy even in summer, but soon becomes hard and dry like wood. In the deserts dead carcasses dried in this manner, and which have become so light that one may easily raise that of a camel, are frequently met with. In the maritime parts, however, such dryness of the air is not to be expected, and the same degree of moisture which is usually met with in such situations prevails. At Rosetta and Alexandria, iron cannot be exposed to the air for twenty-four hours without rusting. The air of Egypt is also strongly impregnated with saline particles. The stones, says Volney, are corroded by natron or mineral alkali; and in moist places crystallizations are to be found which might be taken for saltpetre. The wall of the Jesuits' garden at Cairo, built with earth and bricks, is everywhere covered with a crust of natron, as thick as a crown piece; and when this garden has been overflowed by the waters of the kalidj or canal, the ground, after they have been drained off, sparkles on every side with crystals, certainly not brought thither by the water, which shows no indication of salt either to the taste or by distillation. But whatever may be the quantity of salt contained in the earth, Volney's opinion of its being produced by the air can

---

[1] *Tableau de l'Egypte et de la Nubie*, p. 9, 10.

scarcely be maintained. The salt in question is excessively fixed, and cannot be dissipated into the air without the violent heat of a glass-house furnace; and even after this has been done, it cannot remain diffused throughout the atmosphere, but must quickly descend. No experiments have ever shown that any salt was or could be diffused in the air, except volatile alkali, which is now known to be formed by the union of two permanently elastic fluids; and it is certain that a saline air would quickly prove fatal to the animals who inhaled it. The abundance of this kind of salt in Egypt only shows, therefore, that by some unknown operation the heat of the sun forms it out of the two ingredients of earth and water, though we do not yet understand the manner in which it is effected, nor are we able to imitate this natural operation. To this saline property of the earth is ascribed the excessive quickness of vegetation in Egypt, which is so great that a species of gourd called *kara* will, in twenty-four hours, send forth shoots of four inches in length; but, probably from the same cause, no exotic plant is found to thrive in Egypt. The merchants are obliged annually to send to Malta for their garden seeds; and though the plants thrive very well at first, yet if the seed of them be preserved, and sown a second year, they become too tall and slender.

By reason of the extreme dryness of the air, Egypt is in a great measure exempted from the phenomena of rain, hail, snow, thunder, and lightning. Earthquakes are also seldom heard of in that country; though they have sometimes proved very fatal and destructive, particularly one which happened in the year 1112. In the Delta it never rains in summer, and very seldom at any other season. In 1761, however, such a quantity of rain unexpectedly fell, that a great number of houses built of mud walls tumbled down, in consequence of being soaked with the water. In Upper Egypt the rain is still less frequent; but the people, sensible of the advantages which result from it, always rejoice when any falls, however insufficient it may be to supply their wants. But this want of rain is supplied by the water of the inundation, and by the heavy dews already mentioned. The latter originate partly from the waters of the inundation, and partly also from the sea. These dews are more or less copious according to the direction of the wind. They are produced in the greatest quantity by the westerly or northerly winds, which blow from the sea; but the south and south-east winds, blowing over the arid deserts of Africa and Arabia, produce none whatever.

The periodical return of winds from a certain quarter is a very remarkable phenomenon in this country. When the sun approaches the tropic of Cancer, they shift from the east to the north; and during the month of June they always blow from the north or north-west. They continue northerly all the month of July, only varying sometimes towards the east, and sometimes in a contrary direction. About the end of the latter month, and during the whole of August and September, they blow directly from the north, and are of but moderate strength, though generally weaker in the night than during the day. Towards the end of September they return to the east, though they do not absolutely fix in that point, but blow more regularly from it than from any other except the north and north-west. As the sun approaches the southern tropic they become more variable and tempestuous, blowing most commonly from the north, north-east, and west, which they continue to do throughout the months of December, January, and February; and, during that season, the vapours raised from the Mediterranean condense into a mist, and even sometimes into rain. Towards the end of February, and during the succeeding month, the winds blow more frequently from the south than from any other quarter. During the whole of the months of March and April they blow from the south, south-east, and south-west; sometimes from the north and east, the latter winds being most prevalent about the end of that month, and continuing during the whole of May. "Les vents d'ouest et de nord-ouest," says Rifaud, "poussent vers l'Egypte les sables des déserts de l'Afrique. Ces sables, après avoir franchi la chaîne Libyque, descendent dans la vallée, et rétrécissent de plus en plus la bande de terrain cultivable. Ces sables, uniquement composés de grains quartzeux, s'accumulent en dunes en quelques endroits."[1]

It is to the long continuance of the north winds, formerly denominated the Etesian winds, that Egypt probably owes its extreme dryness, as well as part of the inundation by which it is fertilized. From the month of April till July there appear to be two immense currents in the atmosphere; the under one blowing from the north, and the upper one from the south. By the former the vapours are raised from the Mediterranean and the southern parts of Europe, whence they are carried over Abyssinia, and dissolve on the lofty chains of the interior in immense deluges of rain; whilst by the latter the superfluous vapours, or those raised from the country of Abyssinia itself, are carried northward toward the sources of the Euphrates, where the clouds coming from the south, and descending into the lower part of the atmosphere, dissolve in like manner into rain, and produce an inundation of the Euphrates similar to that of the Nile, and immediately succeeding it. Bruce had an opportunity of ascertaining this fact in the month of June 1768; for whilst on a voyage from Sidon to Alexandria, he observed great numbers of thin white clouds moving rapidly from the south, and in direct opposition to the Etesian winds.

Besides the ordinary winds here spoken of, Egypt is visited with the destructive blasts common to all tropical countries which have extensive deserts in their neighbourhood. The most destructive of these has been distinguished by various names, such as poisonous wind, hot wind, Samiel, the wind of Damascus, Khamsin, and Simoom. These are different names for the same wind, which is denominated Khamsin in Egypt, Samiel in Arabia, and Simoom or Seimoum in the desert. "Dès que ce vent de sud commence à souffler, l'atmosphère se trouble; une teinte pourpre plus ou moins vive la colore; le ressort de l'air et son élasticité cessent; une chaleur seche et brûlante les remplace, en même temps que des tourbillons, semblables aux émanations d'une fournaise ardente, se succèdent par intervalles. Lorsque cet état de l'atmosphère n'est que faible, il cause un mal-aise général, dont tous les êtres organisés se ressentent; à un degré plus intense, il rend malade, et peut même causer la mort."[2] Blasts of this description are in Egypt denominated "winds of fifty days," because they most commonly prevail during the fifty days preceding and following the equinox; though, were they to blow constantly during one half of that time, an universal destruction would be the consequence. Of the effects of these winds travellers have given various descriptions. Volney states that the violence of their heat may be compared to a large oven at the moment of drawing out the bread. They always blow from the south, and are undoubtedly produced by the motion of the atmosphere over extensive tracts of hot sand, by which it is deprived of its moisture, and heated as if it had passed through a furnace. When they begin to blow, the sky (as stated by Rifaud in the passage already quoted) loses its usual serenity, and assumes a dark, heavy, and alarming aspect; even the sun himself lays aside his usual splendour, and becomes of a violet colour. This terrific appearance seems not to be occasioned by any real haze or cloud in the atmosphere at that time, but solely by the vast quantity of fine sand carried along by these winds, and which is so excessively subtile that it penetrates everywhere. The motion of this wind is always rapid, but its heat is not intolerable till after it has continued for some time. Its pernicious qualities are evidently occasioned by its excessive avidity for moisture. It dries and shrivels up the skin; and the lungs being also powerfully affected by it, suffocation and death sometimes ensue. The danger is greatest to those of a plethoric habit of body, or who have been exhausted by fatigue; and putrefaction soon takes place in the bodies of such as have fallen victims of "the hot breath of the desert." Its extreme dryness is such that water sprinkled on the floor evaporates in a few minutes; all the plants are withered and stripped of their leaves; and, in the case of human beings, fever is instantly produced by the suppression of perspiration. It usually lasts three days, but is altogether insupportable if it continue beyond that time. The danger is greatest when the wind blows in squalls, and when travellers happen to be exposed to its fury without any shelter. The best method in this case is to stop the nose and mouth with a handkerchief. Camels, by a natural instinct, bury their noses in the sand, and remain in this position until the gust has passed by. The inhabitants who have an opportunity of retiring to their houses, instantly shut themselves up, or descend into pits made in the earth, till the destructive breath of the desert be overpast.

---

[1] *Tableau de l'Egypte et de la Nubie*, p. 10.

[2] *Tableau de l'Egypte et de la Nubie*, p. 8.

The description of a blast of this kind which overtook Bruce in the desert of Nubia is still more striking than that given by Volney. Pillars of moving sand, raised by the winds in the desert, were observed by the traveller on this occasion in all their terrific majesty. Sometimes they appeared to move slowly; at other times they rushed on with incredible swiftness, so that they could not have been avoided by the fleetest horse. Sometimes they approached so near that they threatened destruction to the whole company. Frequently the tops, having reached an immense height, so as to be lost in the clouds, suddenly separated from the columns, and dispersed themselves in the air; sometimes the whole column broke off near the middle, as if it had received a cannon shot; and the size of some of the columns was such that at the distance of three miles they appeared about ten feet in diameter. Next day, however, they seemed of a smaller size, but more numerous, and sometimes approached within two miles of the party. The sun was now much obscured, and the transmission of his rays gave the columns of sand an appearance resembling pillars of fire. This was pronounced by the guide to be a sign of the approaching Simoom or hot wind; and he directed, that when it arrived, the people should fall upon their faces and keep their mouths on the ground, in order to avoid inhaling this pernicious blast. On his calling out that the Simoom was coming, Bruce turned for a moment to the quarter whence it came, which was the south-east. It appeared like a haze or fog of a purple colour, but less bright than the purple part of the rainbow, and seemed about twenty yards in breadth, and twelve feet above the ground. It moved with such rapidity, that before he could turn round and fall prostrate, he felt the vehement heat of its current upon his face; and even after it had passed over, which was very quickly, the air that followed was of such a heat as to threaten suffocation. Bruce had unfortunately inhaled some portion of the pernicious blast; by which means he almost entirely lost his voice, and became subject to an asthmatic complaint, from which he did not recover for nearly two years. The same phenomenon occurred twice afterwards during the journey through this desert. The second time, the blast came from the south a little to the east, and seemed to have a shade of blue blended with the purple, its edges being less perfectly defined; and it resembled a thin smoke, having about a yard in the middle tinged with blue and purple hue. The third time, it was preceded by an appearance of sandy pillars more magnificent than any which had yet been observed; and the sun shone through them in such a manner as to give to those which were nearest the appearance of being spangled with stars of gold. The Simoom which followed had the same blue and purple hue as before, and was followed by a most suffocating wind, which lasted for about two hours, and reduced our travellers to the lowest degree of weakness and despondency. This wind always came from the south-east, whilst the sandy pillars, which prognosticated its approach, kept to the westward, and occupied the vast circular space inclosed by the Nile to the west of the route followed by the travellers, sweeping round by Chagre towards Dongola. The heaps of sand left by them when they fell, or raised by the whirlwinds which carried them up, were twelve or thirteen feet in height, and exactly conical in shape, tapering to a fine point, whilst their bases were well proportioned.

Though the climate of Egypt is far from being unhealthy, yet there are not a few diseases which seem to be peculiar to that country, and originate either in the constitution of the atmosphere, or in the manner of living among the inhabitants. Till lately the plague was supposed to be one of these native diseases; but it is now agreed that this distemper never originates in the interior parts of Egypt; it always begins at Alexandria, and passes thence successively to Rosetta, Cairo, Damietta, and the rest of the Delta. It is likewise observed that its appearance is almost invariably preceded by the arrival of some vessel from Smyrna or Constantinople; and if it has been very violent in either of these cities, the danger of Egypt is just so much the greater. In fact, it is found to be in reality a native of Constantinople, whence it is exported by the absurd negligence of the Turks, who refuse to take any precautions to prevent the spreading of the infection. As they sell even the clothes of the dead, and as ships laden with this pernicious commodity used to be sent to Alexandria, it is no wonder that it should have made its appearance in the latter place. As soon as it is found to have reached Cairo, the European merchants shut themselves up with their families in their khans or lodgings, and take care to have no further communication with the city. But there is a remarkable difference between the plague at Constantinople and that which occasionally appears in Egypt. In the former place, it is most violent in summer; but in the latter, winter is the season of danger, the disease always disappearing in the month of June. It is also observed, that the water-carriers of Egypt, whose backs are constantly moist, from the nature of their occupation, never take the plague. Every fourth or fifth year, Egypt was till latterly visited with this dreadful scourge.

A malady which seems to be peculiar to Egypt is blindness. This is so common at Cairo, that out of a hundred persons whom Volney accidentally met on the streets he reckoned twenty quite blind, ten without the sight of one eye, and twenty others with their eyes red, purulent, or blemished. Almost every one wears a fillet, which is a token of an approaching or convalescent ophthalmia. In considering the causes of this disorder, Volney reckons the sleeping upon terraces as a principal one. The south wind cannot, according to him, be the cause, otherwise the Bedouins would be equally subject to it with the Egyptians themselves; but the principal cause, he thinks, is the poor and little nutritive food on which the natives are obliged to subsist.[1] The cheese, sour-milk, honey, confections of grapes, green fruits, and raw vegetables, which are the ordinary food of the common people, produce in the stomach a disorder which physicians have observed to affect the sight; and the raw onions, especially, which they devour in prodigious quantities, have a peculiarly heating quality. Bodies thus nourished abound in corrupt humours, which constantly seek a discharge; and, diverted from the ordinary channels by habitual perspiration, these humours fly to the exterior parts, and fix themselves where they find the least resistance. They therefore naturally attack the head, because the Egyptians, by shaving it once a week, and covering it with a prodigiously hot head-gear, principally attract to it the perspiration; and if the head receive ever so slight an impression of cold on being uncovered, this perspiration is suppressed, and falls upon the teeth, or still more readily on the eyes as being the tenderest part. The ancient Egyptians, who went about bareheaded, are not mentioned by physicians as having been so much afflicted with ophthalmia as the modern; and the Arabs of the desert, who cover their heads slightly, especially when young, are but little subject to this disease. In Egypt, blindness is often the consequence of small-pox; a disorder which, until lately, when vaccination was partially introduced by Mehemmed Ali, used to be very frequent and fatal. Another cause of this distemper may perhaps be found in the fine impalpable sand which is carried about by the wind, and also in the intolerable brilliancy of the sunbeams reflected from a burning and sandy soil impregnated with nitrous salt.

Besides these, there are two diseases less commonly met with in Egypt; namely, a cutaneous eruption, which returns annually, and a swelling of the testicles, which often degenerates into an enormous hydrocele. The former comes on towards the end of June or beginning of July, making its appearance in red spots and pimples all over the body, which occasion a very troublesome itching, and is probably occasioned by the waters of the Nile, which towards the end of April become putrid. The hydrocele most commonly attacks the Greeks and Copts, and is attributed to the quantity of oil which they make use of, as well as to their frequent hot bathing. In the spring season malignant fevers occasionally prevail. In the treatment of these bleeding is found prejudicial, whilst vegetable diet, and bark in large quantities, have been found useful.

We have already described the geographical configuration of the valley of the Nile, with its natural boundaries consisting of two elevated ridges between which the river flows for about a hundred and fifty leagues. These mountain chains are on many accounts highly deserving of attention, but on none, perhaps, more than by reason of their geological structure and characters. After passing through a district of primitive formation, they enter that of the secondary and flœtz-trap kind, and terminate in deposits belonging to the most recent species of stratified rocks.

The granite or southern district extends from Philœ to Assouan, in 24° 8′ 6″ N. and 33° 4′ E., and consists for the most part of syenite or oriental granite, in which may still be observed the quarries whence the ancient Egyptians detached the stupendous monoliths required for their colossal statues and obelisks. The granite is occasionally diversified by alternations of gneiss, porphyry, clay-slate, quartz, and serpentine, erroneously described as a green-coloured marble, containing imbedded in them a variety of carnelians and jaspers; and there has also been observed in this district a granular foliated limestone or marble, exhibiting various hues, as white, grey, yellow, blue, red, and, when combined with serpentine, forming the rock known by the name of verde-antico. From the quarries of Philœ, Elephantine, and Syene, were obtained the beautiful oriental or rose-coloured granite, called *syenites* by Pliny, from the place near which it abounded, but differing from the syenite of modern mineralogists. In this rock two thirds of the mass consists of felspar, varying in colour from a pale pink to a brick red; and the remainder is composed of mica exhibiting a metallic lustre, and diaphanous quartz, with sometimes a small quantity of hornblende, in which case it becomes the syenite of Werner. Pliny denominates it Thebaic stone, not from there having been any quarries of this rock in the neighbourhood of Thebes, but from the frequency of its occurrence in the gigantic monuments of the ancient capital of Egypt. The rose-coloured variety seems chiefly confined to the vicinity of Elephantine, though it is also found unmixed for some distance on both sides of the river. As syenite is connected by numerous shades and gradations both with the common granite and also with the succeeding species of rock, so we have accordingly the granitello of lapidaries when it is fine grained, grey syenite when the felspar is of that colour, black and white granite when the felspar is white and the mica black, and Egyptian or oriental basalt when it has been extracted from veins in which the mica and hornblende prevail in black homogeneous masses, with scarcely any admixture of felspar. The hardness of this stone is such as to preserve its surface uninjured by exposure to the atmosphere. But the remarkably perfect state in which the monuments of Egypt are found ought perhaps to be ascribed to the uniform dryness of the air, and the almost total absence of rain; and this is rendered more probable by the circumstance, that in the Delta, especially near the sea, where showers occasionally fall, and the atmosphere is charged with a greater quantity of moisture, the process of decomposition has commenced, and in some places made considerable progress.[2]

Between Assouan and Esneh, in 25° 19′ 39″ N. is the argillaceous sandstone or middle district, which supplied slabs for most of the temples; and beyond it the northern or calcareous district stretches to the southern angle or vertex of the Delta. At Esneh, indeed, the rocks assume the calcareous character, and retain it until they merge into the plain below Cairo, at the southern limit of the lower division of Egypt. From this last chain were quarried, not only the solid part of the Pyramids, but also materials for many public buildings, which, as they proved excellent stores of lime and stone for the Arabs and other barbarians who for so many centuries desolated Egypt, have long since been destroyed. The steep perpendicular cliffs of this limestone formation impart to the portion of the country where it prevails a hard and monotonous aspect, contrasting unfavourably with the bold and picturesque forms of the mountains in the south, which offer new points of view in continual succession, and give an agreeable variety to the landscape, even when the inundation is at its greatest height. The limestone of this region exhibits a splintery or conchoidal fracture, is grey or variegated in colour, and contains numerous petrifactions of shells, corals, and fishes. A similar rock occurs in the ridges bounding the transverse valley which leads to Cosseir; and in the same mountain district there are hills of limestone conjoined with gypsum. Here also the sand is partly calcareous and partly quartzose, thus indicating the composition of the strata from the debris of which it has been formed. The site of the ancient capital of Egypt is at the lower limit of the middle or sandstone district, and from the quarries of Djibbel-el-Silsileh or the Mountain of the Chain, were obtained the materials used in the construction of its stupendous temples and palaces. Here the sandstone terminates and the freestone begins; the hills are no longer parallel, but diverge in various directions; and on the first level of any extent below the Cataracts are found the ruins of Thebes, covering a large portion of the valley. From this point the calcareous chain continues on each side of the valley to the summit or vertex of the Delta, where the hills open to the east and west, uniting with the Libyan chain on one side, and inclining towards the mountains of Arabia Petræa on the other. But though generally calcareous, this chain, especially near the desert, is occasionally intersected by isolated masses of sandstone.[1]

---

[1] This is no doubt one cause of the distemper; but Rifaud has shown that there are others. "On a attribué la fréquence des ophthalmies en Egypte aux vents qui soufflent périodiquement; je croirois plutôt pouvoir trouver la cause de cette maladie dans l'habitude où sont les Egyptiens de coucher sur les terrasses pendant neuf mois de l'année. Il faut considérer que les campagnes de l'Egypte sont d'immenses plaines, où la lumière est très vive; leur terrain est sec, friable, et brûlant, particulièrement en été; il est argilleux et crayeux, contenant le nitrate de potasse, le natron, et le muriate de soude. D'ailleurs, les jours sont d'une chaleur excessive, tandis que les nuits sont fraîches, humides, et nébuleuses. Ces circonstances physiques réunies ne peuvent agir sur l'organe de la vue sans y causer des désordres. On a remarqué que les ophthalmies sont plus communes en été qu'en hiver, et que les animaux y sont sujets aussi-bien que les hommes. (Rifaud, *Tableau de l'Egypte*, p. 9.)

[2] *Encyclopædia Metropolitana*, art. *Egypt*.

But the most singular portion of Egypt, in a geological point of view, is that which is comprehended in the Bahr-bilama or waterless sea, and the basin of the natron lakes. These two valleys run parallel to each other. The mountain of natron skirts the whole length of the valley of that name, but it contains none of the rocks which are found scattered about in the valley, such as quartz, jasper, and petrosilex. In the direction of this valley is a series of six lakes, the banks and waters of which are covered with crystallizations consisting of muriate of soda or sea salt, and carbonate of soda or natron. When a volume of water contains both these salts, the muriate of soda is the first to crystallize, and the carbonate of soda is then deposited in a separate stratum; but the two crystallizations sometimes affect separate localities in insulated portions of the same lake. The ridge which separates the basin of the natron lakes from the valley of the Bahr-bilama consists chiefly of natron mixed with muriate of soda, which salt is also found in the valley of the wilderness in thin compact layers supported by strata of gypsum, and in other deserts, where it occurs in a state of crystallization, sometimes under the sand, but much more frequently upon the surface. The valley of the Bahr-bilama, separated, as already described, from that of natron, is about eight miles in breadth. In the sand with which its surface is everywhere covered, trunks of trees have been found in a state of complete petrifaction. It is thought by some that a branch of the Nile once passed in this direction.[2]

Of the more precious minerals found in Egypt we shall only give a brief enumeration. The topaz, which is said to have attracted the attention of some ancient kings, is still found in various places, particularly in an island called Zamorget, or the island of topazes, in the Red Sea. Emeralds were anciently obtained by means of excavation, in the mountainous ridge which skirts the western shores of the Arabian Gulf, and constituted an article of commerce among the Romans; and Bruce speaks of an island of emeralds in the same sea, but, upon examination, it was found to produce nothing more valuable than fluor spar. Chrysoberyl is also enumerated amongst the mineral productions of Upper Egypt. The rarest varieties of quartz to be met with in any part of Africa are the Egyptian avanturine, and the rock-crystal of the northern shores. Chalcedony and carnelian have been picked up on each bank of the Nile, both in the upper and lower provinces. Agate belongs to the rocks which diversify the monotony of the desert to the eastward of Cairo. Jasper occurs in veins of considerable thickness in the clay-slate which bounds the upper part of the valley of the Nile, between Esneh and Siout; but a finer kind, for which Egypt has long been celebrated, is found both in the sandy waste between Cairo and Suez, and also in that part of the country below Benisouef, where it occurs imbedded in a species of conglomerate. Actynolite, epidote, and hornblende, to which may be added heavy spar, or sulphate of barytes, are frequently to be met with in the transverse valleys which diverge from Upper Egypt towards the Red Sea, particularly in the valley of Cosseir.

The mountains of Egypt, and those of the countries immediately contiguous thereto, have been so imperfectly explored that we are still ignorant of the amount and diversity of their metallic treasures. But, from the early advancement of the useful arts in Egypt, and particularly from the gigantic labours of the Anakim of ancient days, in not only detaching but working into a great variety of forms enormous blocks of the hardest granite, it may safely be concluded that iron was not unknown to them, that it must have been found at no great distance from the great works in which it was employed, and that the subjects of the elder Pharaohs were also acquainted with the method of converting it into steel. Their quarries whence gigantic blocks were detached, their obelisks covered with hieroglyphics frequently cut in relief, and their statues chiselled out of the hardest rock, indicate, in a manner not to be misunderstood, that instruments of the best temper must have been placed in the hands of their workmen and artists, and that they wrought with tools of the finest steel, which, of course, they must have known how to prepare. With regard to the precious metals, although Africa affords a considerable quantity of gold, which is obtained in the form of dust, or collected by washing from the sand of rivers or the alluvial soil of valleys between ranges of mountains, yet the position of Egypt deprives it, in a great measure, of this source of wealth. But in the countries above the Cataracts, particularly in Kordofân, there are several tracts where this metal is found in considerable quantities; and hence, probably, arose the opinion, so prevalent amongst the ancients, that Ethiopia was a country which abounded in gold. In our time, however, the supply of this metal received at Cairo and Alexandria is derived from that elevated region which contains the sources of the Gambia, the Senegal, and the Niger, and from the district of Bambouk, situated to the north-west of the lofty range which forms as it were the back-bone of the African continent. Of silver, copper, lead, and antimony, no traces whatever are to be found below Abyssinia. To Egypt nature having given the Nile, seems to have considered that precious gift, annually renewed, as an adequate compensation for the want of products far less available to the wants and necessities of man.[3]

[3] Murray, *Historical Account of Travels and Discoveries in Africa*, vol. ii. pp. 424, 438. Lyall, *Principles of Geology*, vol. i. p. 238.

These geological notices are, we admit, exceedingly imperfect. But hitherto travellers have, from various causes, bestowed much less attention on the geology of Egypt than the subject unquestionably requires; and, even in Lyall's *Principles* of this science, all that we meet with respecting either the valley of the Nile or the Delta is at once so meagre and superficial that it deserves to be signalized only for its want of satisfactory information. As yet no extensive or connected series of observations has been made in regard to the direction and inclination of the strata, either in the mountainous ridges within which the Nile is confined, or in the transverse valleys which branch off towards the Red Sea on the one hand and the Oases on the other; and although we are reminded of the usual mineralogical distinctions, and meet with much learned phraseology about primitive, secondary, flœtz, and alluvial formations, yet we search in vain for any thing like systematic views based on accurate observation, and are thus compelled to rest satisfied with conjecture, where, if facts had been supplied, we might have been in a condition to reason on established philosophical principles. Egypt is therefore a field which is still in a great measure unexplored by the scientific geologist, but it is nevertheless one which will amply repay the judicious and persevering labourer; and we trust that the period is not distant when a regular mineralogical survey will be executed of a country which, all circumstances considered, is certainly one of the most remarkable and interesting upon the face of the earth.

SECTION IV.

POLITICAL GEOGRAPHY AND ACTUAL STATE OF EGYPT.

Ancient and modern divisions of Egypt.—Relative positions of the provinces of each division.—Population.—Turks, Copts, Arabs.—Distinction between the Arabs and Copts.—Descent of the latter.—The Coptic language.—Turks.—Greeks.—Jews.—Total population.—Civil government of Egypt.—Court and household of the Viceroy.—Local authorities.—Tenure of land.—Mode in which it is cultivated.—Condition of the Fellahs or Cultivators.—Canal of Mahmoudyeh, between the Nile and Alexandria.—Circumstances which led to and attended the construction of this great work.—Trade of Alexandria.—Progress of the cultivation of cotton, and the introduction of cotton manufactures.—Quantity of raw cotton exported.—Silk, flax, sugar, tobacco, and other commodities.—System of monopoly and pre-emption.—Its disadvantages and probable results.—Indian trade.—Imports and exports.—Caravans.—Statistics of Egypt.—Comparative condition of that country before and under the government of Mehemmed Ali.—Its future prospects.—General reflections.

In modern as well as in ancient times, Egypt is divided into three principal parts: namely, the *Bahhari*, corresponding to the Delta or Lower Egypt; the *Vostani*, corresponding to the Heptanomis, or Middle Egypt; and the *Saïd*, corresponding to the Thebaid, or Upper Egypt. This division is indicated by the course of the river and the configuration of the country. The Bahhari, or Lower Egypt, includes the provinces of Bahhireh, Rosetta or Raschid, Gharbieh, Menouf, Manssourah, and Sharkieh. The Vostani, or Middle Egypt, comprehends those of Cairo, Gizeh, Attafieh, Kelioubeh, Fayoum, and Benisouef. The Saïd, or Upper Egypt, consists of the provinces of Siout, Djirdjeh, and Kenneh or Thebes.

The province of Bahhireh occupies the north-western province of Egypt, but is not comprised in the Delta properly so called. Its limits are the Mediterranean towards the north, and on the east and south-east the branch of the Nile between Darasoueh and Rosetta; whilst a line, exterior to Lake Mareotis, commencing at the Arabs' Tower, and sweeping to the south-east, would complete the circumscription of the province. The principal places of Bahhireh are, Alexandria and Aboukir on the coast, and, ascending the Rosetta branch of the Nile, the towns of Deïrout, Rhamanieh, and Damanhour. To the west and south-west of this province is the valley of natron, or the valley of the waterless sea. The province of Rosetta is inconsiderable, and stretches along the right bank of that arm of the Nile which terminates at the bogaz. Its most important point is the town of Rosetta. Gharbieh extends from the sea on the north, where it borders with the province of Rosetta, to that of Menouf on the south. The capital of Gharbieh is Mehallet-el-Kebir; and this province also contains the towns of Fouah, Samanhout, Tintah, and Zephteh. Lake Bourlos is situated in this province. Menouf is at the vertex of the angle formed by the two branches of the Nile which proceed, the one to Rosetta, and the other to Damietta. The capital is Menoufyeh, to the south-west of which are the village of Melik and the fort of Taoueh. The province of Manssourah extends to the right of the Damietta branch of the river, and is bounded on the north by Lake Menzaleh. In proceeding from the north to the south, the traveller successively reaches the village of Esbeh, and the towns of Damietta, Farescout, and Manssourah. On the eastern bank of Lake Menzaleh is the town of the same name. Sharkieh is situated to the east of the canal of Moez. This canal, which is the ancient Tanitic branch of the river, commences at the place where the ruins of Abril are observed, close to Banha, and runs north-east into Lake Menzaleh, at no great distance from the site of the ancient Pelusium. The country between Abril and Pelusium is one of the most fertile in Egypt, and contains several rich towns and villages, such as Guenieh, Heïheh, Karf-Four-Nigheh, and others. The eastern part of the province of Sharkieh is traversed by the road which leads from Cairo to Syria. Belbeis is the most considerable town which the traveller meets with in this direction; then come the group of Horaïn, and the canton of Salahieh, on leaving which he crosses the isthmus of Suez, and reaches El-Arisch, and lastly Gaza, the first town of Syria on the side of Egypt. Such are the different provinces of Lower Egypt, with their relation to one another in point of position.

Passing on to Central Egypt we come to Cairo, the capital of the country. This city stands at the distance of half a league from the Nile, and extends in an easterly direction towards the mountains, about two leagues. It is three or four leagues in circumference, and contains many fine places or squares, nearly three hundred mosques, and from four hundred thousand to four hundred and fifty thousand inhabitants. Boulak, a town situated on the eastern bank of the Nile, is close to Cairo, of which it is the entrepôt or port. Here all the boats which come from Lower Egypt discharge their cargoes. Gizeh or Djizeh is situated on the western bank of the Nile, at a short distance from the Pyramids, which are hence called the Pyramids of Gizeh or Cairo. The town of Gizeh, though of moderate extent, is, in the estimation of Europeans, the most agreeable in all Egypt. The province of Fayoum is situated to the south-west of Gizeh, and is very populous and fertile. Its capital is Medina, a town of some importance. A portion of Fayoum is constantly submerged. At the distance of two leagues from the bridge of Illaoun is the junction of the two great canals which supply it with water. These are the Bahr-Yussuf and the Darout-Scherif. The Bahr-Yussuf extends fifty leagues from the point of the Saïd, where it commences, to that of Fayoum, where it terminates. The province of Benisouef is situated to the south-east of Fayoum. Its capital, Benisouef, distant thirty-eight leagues from Cairo, is one of the most important towns in Egypt. The other places of note are Be-

beh, Fechneh, Abou-Girgeh or Abou-Djirdjeh, and Cheroneh.

Having arrived at the confines of the Saïd, the traveller, if, without leaving the valley of the Nile, he traverse the three provinces of which it is composed, will successively reach Minyeh, in latitude 28° 29′, and Benesef; the islands of Sohorrah and Gerabieh; Saoudi, Abouzir, Tounah, Achmonein, and Salam. Siout, a kind of capital, is situated in latitude 28° 51′; and farther on is Djirdjeh, another large town. Then come the towns of Bardys, Belyneh, Hayou, and Dendera, in latitude 26° 10′, opposite to which is Queneh or Kenneh. Medinet-Abou, Karnak, and Luxor, are situated in latitude 25° 44′ 15″. Still ascending, we next reach Assfoun, then Esneh in latitude 25° 17′, and lastly Edfou, which is six leagues south of Esneh. Assouan, in latitude 24° 27′, is a town at a short distance from the ancient Syene, and the island of Philœ. Four leagues above Kenneh, and nearly opposite Dendera, the ancient Tentyra, is the entrance of the valley of Cosseir, which leads to the port of the same name on the Red Sea.

The population of Egypt is chiefly composed of Turks, Copts, and Arabs, intermixed with Greeks, Jews, and Syrians. The schismatic Copts are estimated at a hundred and sixty thousand, and the Catholic Copts at five thousand souls. But the Arab class is by far the most numerous. It comprehends, first, the posterity of those who came to establish themselves in this country at the epoch of the invasion of Amru in 640, and who appear to have divided amongst them the lands of Lower Egypt, to the prejudice of the conquered Greeks; secondly, the Arabs who at subsequent periods came to join the first invaders, and who settled in Upper Egypt; and, thirdly, the Bedouins, who, instead of applying themselves to agriculture and commerce, live a wandering life, in families or in tribes, dwelling in tents, which they pitch sometimes on the borders of the Nile and sometimes in the desert, and are equally ready to use the arms which they constantly carry about, either for the purpose of plunder or for that of self-defence. The Copts are descended from the people enslaved and dispossessed by the Arabs; that is, from a mixture of Egyptians, Persians, and particularly Greeks, who, under the Lagidæ and the Constantines, so long occupied Egypt. This people differ from the Arabs and from the Turks in their religion, which is a form of Christianity; they differ also in the features of their visage, which exhibits the negro type, and in the colour of their skin, which is of a dingy and as it were smoked yellow. In the Arab the head is of a fine oval form, the forehead large, the eye brilliant but deep set in the head, the nose developed, and the mouth well formed, whilst the bright sunburnt hue of the skin is wholly different from the tarnished colour of the Copts. But as the negro type, if we may judge from the monuments, was that of the ancient Egyptians, and as this type, which is quite distinct from that of the Arabic race, still predominates amongst the Copts, it may hence be inferred that the latter, though a people of mixed origin, have never in any sensible degree amalgamated with the former, and that in the main they are the descendents of the ancient inhabitants of the country. To the Arabs, indeed, the Copts bear nearly the same relation that the Gauls did to the Franks under the first race of French kings; but the permanence of the ancient type shows that the admixture with Persians and Greeks had only been partial, and that amongst this people alone can we hope to find any distinct traces of the forms and language which obtained in Egypt in the days of Rhamses, Mœris, and Amenophis. Even the name which they still bear seems to betray their origin.[1]

That the Coptic language has been formed from that of ancient Egypt, of which it may in one sense be considered as a precious remnant, is proved beyond dispute by the researches of Etienne-Quatremère and Klaproth.[2] But still the modern idiom represents the ancient form of speech in a very incomplete and imperfect manner; and, besides, all that we possess in the former is confined to fragments of the Bible and of the lives of the saints, together with some Copto-Arabic glossaries of a comparatively recent date. The language itself has, moreover, ceased to be spoken; and all that portion of its vocabulary which occurred in the treatises composed by the monks of the Thebaid, is now irrecoverably lost. In the Christian versions all the pagan expressions relative to the ancient religion of the country were also carefully avoided by the translators, who preferred introducing Greek terms; and, from the list of words comprehended in the lexicons, there must further be deducted a great number of Arabic terms, which only found a place there because the original names had been altogether lost. The Coptic, therefore, as it now exists, is only a mutilated and imperfect fragment of a language through which various traces and lineaments of an elder form of speech are more or less faintly reflected; and, like the people from whom it derives its name, it is of mixed origin and impure descent, though not so corrupted, however, as to obliterate the characteristic type of the more ancient language, out of the remains of which it was principally formed. Two dialects of this language have been distinctly recognised, namely, the Bashmuric and the Theban; but, to say nothing of its scanty vocabulary, its general character is that of a rude and almost monosyllabic idiom. It is totally devoid of inflexions; its grammatical modifications are few and limited; and the accidents of gender and case are expressed by prefixes, in which respect it exhibits some affinity to the Hebrew and other oriental languages, particularly the Ethiopic.[3]

The religion of the Copts is that form of Christianity which was derived from the sect of the Eutychians; and the head of their church is the patriarch of Alexandria, who is elected by the great body of the clergy, and is everywhere implicitly obeyed. The officiating ministers are supported by the voluntary contributions of their flocks; and no person can be ordained who is unmarried, nor is any one who has been ordained permitted to marry a second time. But the monks from whose number the bishops are uniformly chosen are bound by their vows to observe strict celibacy; they are supposed to be dead to the world, and are hence prohibited from forming any connexion at variance with this supposition. The Copts practise the rite of circumcision, as well as auricular confession and other ceremonies or observances common both to the eastern and western churches. The great body of them are therefore schismatics; but, as we have already stated, there are at Cairo about five thousand who have conformed to the Roman Catholic communion, and who receive instruction under the direction of certain members of the College of the Propaganda at Rome.

---

[1] The monosyllable *Gopt* or *Kopt* is evidently the root of the word Αι-ΓΥΠ-τος, or Αι-ΓΟΠ-τος, *Ægyptus*. This, we think, has been made sufficiently apparent at the commencement of the present article. (See D'Herbelot, *Bibliothèque Orient.* v. *Kebt* and *Kibt.* Malte-Brun, *Geography*, iv. p. 106. Kircher, *Prodromus Koptus.* Herodotus, *Euterpe.*)

[3] *Edinburgh Review*, vol. lviii. p. 471.

Of the Turks little need be said here. After the taking of Constantinople by Mahommed II. they extended their conquests to the south, and in their turn made themselves masters of Egypt. But a power formed in Egypt as early as the sixth, and destroyed by the Turks at the beginning of the seventeenth century, resumed its ascendency after this long minority, and, excepting some short intervals, during which the Ottoman government displayed extraordinary vigour, domineered over the country, until the period of the French invasion in 1798, when it received a blow from which it never afterwards recovered. It was however reserved for Mehemmed Ali to complete the work which the French had begun, and not merely to destroy the power, but almost to annihilate the very race, of the Mamlukes. The Turks in Egypt are like the Turks everywhere else; men of grave features, sleek forms, fine dark eyes, large noses, handsome mouths, thin lips, short necks, and indolent habits; haughty, obstinate, prejudiced, and reserved, but, when stimulated by fanaticism or revenge, as fearless as the Damascus blades, which they use with so much expertness and address. The Greeks domiciled in Egypt to the regular features unite all the ingenuity and versatility which distinguished their ancestors; and they are charged, we fear not altogether unjustly, with a certain degree of sharpness, if not chicanery, in their mercantile transactions. The Jews in Egypt have the same physiognomy as in Europe, and are there, as everywhere else, devoted to the pursuits of commerce, but despised, insulted, buffeted, and oppressed in a manner which would exhaust the patience of almost any other race of men in existence. In the large towns they enter into competition with the Copts for situations in the customs, and for the management of property belonging to the rich; and, in consideration of gain, they are content to endure every species of contumely which insolent brutality, inflamed by religious hatred, may choose to inflict upon them. There are three thousand of this people in Cairo, where they inhabit a district which bears the distinction of their name, and is remarkable as the spot where, by reason of its crowded and filthy state, the plague commonly makes its first appearance.

Upon the whole, the inhabitants of modern Egypt may be rated and classed as follows:

Copts	160,000
Arab Fellahs	2,250,000
Bedouin Arabs	150,000
Arabian Greeks	25,000
Jews	20,000
Syrians	20,000
Armenians	10,000
Turks and Albanians	20,000
Franks or Levantines	4,000
Mamlukes	500
Ethiopians and others	7,500
Total	2,667,000

Egypt, formerly a dependency of Turkey, is now in reality, if not altogether in name, independent of the Porte, and is governed with absolute and unlimited authority by a man who, still retaining the title of pasha or viceroy, is content, under that denomination, to exercise all the rights and powers of a sovereign prince. The ancient form of the administration has, however, been preserved; and the present ruler, aware of the influence exerted on the minds of men by custom and names long familiar, has been careful to innovate as little as possible on the modes by which the country has hitherto been governed, or on the denominations of the government. The first administrative functionary is the kiaya-bey, or prime minister; under whom are placed all the secondary authorities, invested with powers conferred on them by the viceroy, and to whose office or tribunal all representations and private complaints, as well as the greater part of litigious disputes, are carried. The aga of the janizaries is charged with maintaining good order, and watching over the conduct of the troops. The wali, or aga of the police, exercises similar functions: he is the head of the gendarmerie; and his principal duty is to observe public women, and to pursue and seize all thieves and robbers. The direction of the markets, and the examination of weights and measures, are entrusted to the mohteseb, or aga of subsistence. The bash-aga, or superintendent of the civil police, causes the orders of the government to be executed, the streets to be patrolled day and night, and the coffee-houses and other public places to be watched by spies in his employment. In each quarter or district of the capital there is also a headsman or overseer, who is empowered to settle differences by arbitration, and is responsible for the peace and good order of his neighbourhood. All sorts of exactions, whether in the shape of fees or presents, have been abolished, and adequate salaries allotted in their stead; nor is it permitted to any officer, except the wali, who retains his former rights over prostitutes and thieves, to levy contributions on any pretext whatsoever. By the vigilance of the police, civil and military, and the activity of the district magistrates in removing bad subjects and allaying disturbances of every kind, the streets of Cairo have been rendered as safe as those of London, excepting only in the case of military tumults, which are now of rare occurrence; and by the extension of the same system throughout the country, crimes have been repressed, security afforded to person and property, and order established, in a land which was formerly filled with anarchy and violence.[1]

The administration of justice has in like manner been improved, by being purified from some of the enormous abuses which formerly prevailed; but still, in Egypt as in other countries much farther advanced, the poor litigant contends at a great disadvantage with his rich adversary, and the law is even yet sometimes scandalously eluded in favour of the powerful. The cadi is the supreme judge, and holds his appointment only for a year; but he has under him sheikhs and other men of the law, who are not removeable. The procedure before this judge is, as might be expected, exceedingly simple. The nature or relevancy of the process is first inquired into; parties are then fully heard, and witnesses, if necessary, examined; after which the members of the court deliver their opinions, and according to these the cadi at last decides. When the cadi is an easy, pacific man, the sheikhs convert their own houses into courts or tribunals, and arrogate to themselves the right of dispensing justice; but they discontinue their usurpations whenever they observe the supreme judge evince dispositions adverse to their interested views. The cadi also exercises the functions of a notary, and passes all contracts for the sale of real property, denominated *heggeh*, exacting a fee or duty of two per cent. upon each. The average cost of a lawsuit is stated at four per cent. of the value in dispute; and of this proportional charge, which is paid down whenever judgment is pronounçed, the cadi allows one fifth to the lawyers employed in his tribunal, and judiciously keeps the remaining four fifths to himself. He has, besides, other emoluments, which, added to the fees thus exacted, render his situation worth from five to six hundred purses, or between L.2000 and L.3000 a year. With regard to his assessors, they are not considered as at all scrupulous about the means of improving their incomes; and in truth they are accused of resorting to practices incompatible with the slightest pretension on their part to judicial purity.

---

[1] Mengin, *Histoire de l'Egypte sous Mohammed-Aly*, tom. ii. p. 255 et seqq.

Besides the public functionaries above mentioned, there are others attached to the household or court of the viceroy; which is composed of the kiaya-bey or head of the civil administration, the khaznadar or treasurer, the divan-effendi or inspector of provisions, the selikdar or master of the household, the anaktar-aghassi or keeper of the wardrobe, the commandant of the citadel, and the superintendent of customs and excise, who are all paid by fixed salaries, so considerable in amount that some of them have been enabled to realize fortunes. The viceroy has also a body-guard, consisting of several hundred Mamlukes, and about six hundred yeomen of the palace; so that the establishment of his household, including subordinate functionaries in the civil and military departments, cannot be much short of fifteen hundred individuals. Many of these, however, are persons whom, on account of their merit, he has sought to attach to his service by placing them on his establishment, and who either hold nominal offices, or are kept as mere retainers until an opportunity offer for employing them to advantage.

The Saïd is governed by a pasha of two tails, who resides at Siout; and other pashas and beys are also placed at the head of the different branches of the administration, as already stated. Each province is divided into cantons; and these cantons are placed under the authority of the kiachefs and kaimacans, with whom are conjoined in office the cherbalettes for the direction of rural economy, and the cadis for administering justice. Each canton has also its scheraf for the collection of the contributions, which he transmits quarterly to the treasury of the grand divan; but the collections of Upper Egypt are, we believe, centralized at Siout, whence they are remitted to Cairo.[1]

It is exceedingly difficult, not to say impossible, to ascertain by what precise tenure land was held under the princes of the native dynasties by whom Egypt was anciently governed; but, judging from some papyral writings which modern ingenuity has deciphered, as well as from certain hints both in sacred and profane history, it seems evident that, in the days of the Pharaohs, a distinct property in the soil, however modified or affected, was recognized by the Egyptian monarchs. This, in fact, is attested by the title-deeds which have been found in the mummy-chests or coffins; and it may also be inferred from the transaction mentioned in Scripture, where Joseph transferred to the crown a large portion of land, giving to the famished peasantry, in return for their fields, a certain quantity of corn. It may also be observed in support of the opinion here stated, that, in the great Turin papyrus deciphered by Count Pollon, there is a very intelligible intimation of something like a law of prescription for securing persons whose right has not been challenged within a given time (thirty-eight years), in the undisturbed possession of their property; a circumstance which seems perfectly conclusive as to the existence of a distinct property in the soil, however that right may have been modified or restricted by the fundamental laws of the monarchy. This rule, by which unchallenged possession for a given period of time was sustained against a claim founded upon title alone without possession, appears to have been first laid down in a royal edict or decree, which is denominated "the benevolent," and to which accordingly distinct reference is made in the very remarkable monument to which we have alluded. For a long period subsequent to the Macedonian conquest, however, the territorial domain of Egypt appears to have been occupied on conditions somewhat analogous to those implied or involved in the system of fiefs or feudal tenures, which was at one time universal throughout Europe: the actual property of the soil was vested in the vassal; but a certain portion of the annual produce, or an equivalent for such portion, was made payable to the individual on whom the monarch, theoretically the proprietor of all the lands in the kingdom, had conferred the usufructuary interest, if not the feudal superiority.

Before the accession of the present viceroy, the representative of the Ottoman Porte was satisfied with levying a miri or land-tax, proportioned to the estimated value of the soil in point of quality and other advantages, and he at the same time acknowledged a quasi-right of ownership in the occupants, subject only to the payment of the territorial impost. But at present nearly all the lands, as well as the commerce and manufactures, of Egypt, belong to Mehemmed Ali; who, having assumed possession of the territorial property of the country, granted, in name of compensation, to the former holders who were thus deprived, annuities or pensions for life, but left them nothing which they could transmit to their children or their heirs. The lands which were seized in this way belonged either to the Mamlukes, whom it was the policy of the viceroy, if not wholly to extirpate, at all events to disconnect and detach from every means of regaining power; or to certain establishments for feeding the poor, and supporting mosques, fountains, public schools, and other similar institutions; or, lastly, to the ancient class of proprietors in feu-hold, whose principles or management were not such as to secure the confidence of the viceroy. But even the owners of those lands which have as yet escaped seizure are not the masters of the crops which they raise; they cannot dispose of any part of the produce until the agents of the government shall have had the pre-emption of such portion as they may think fit to take at a price fixed by themselves; and, besides paying the established miri, or land-tax, they are bound to supply all the families attached to the court with agricultural produce at half its current price in the market, whilst the viceroy regulates the price of such surplus as can be spared for exportation.

With regard to those lands of which the absolute property is now vested in the viceregal government, they are let or farmed out in portions at fixed rents to the cultivators, who may sow as they please, or not sow at all, but who, whether the seasons be propitious or the reverse, must pay the stipulated rent, which is exacted with the utmost rigour; and as this is invariably fixed at the highest limit to which it can possibly be carried, the condition to which the Fellahs or cultivators have in consequence been reduced is one of extreme misery and wretchedness. This unhappy class, which seems destined to be equally oppressed whoever be master, and which feels the government of Mehemmed to be even more grinding in its exactions than either that of the Turks or the Mamlukes, whom he superseded, is almost the only one which has derived no benefit from the various reforms he has introduced; and its situation would in fact be altogether intolerable and hopeless, were it not that the large standing army, which is principally recruited from the native population, opens up a field for the development of talent and enterprise, and holds out a certain and not very distant prospect of amelioration in the condition of this degraded caste. The natural fruits of such a system, however, are general abundance and individual misery;—the traveller sees with astonishment the richness of the harvests contrasted with the wretched state of the mud villages inhabited by the peasantry; and whilst he is convinced that no country is more prolific than Egypt of all those products which minister to the wants of man, he is also satisfied that there is none perhaps where the great body of the people are upon the whole more miserable.[1]

---

[1] Rifaud, *Tableau de l'Egypte et de la Nubie*, p. 23.

In Egypt there are about four millions of feddâns[2] of land in cultivation. A feddân produces three ardebs or six quintals of cotton at the least, the same quantity of flax, from twelve to thirteen okes, or from fifteen to sixteen kilogrammes, of refined indigo, seven or eight ardebs of sugar, and other articles in proportion. Cultivation may be divided and classed as follows:

Cotton	200,000 feddâns.
Flax	100,000
Hemp	100,000
Indigo	100,000
Rice	100,000
Sugar canes	100,000
Dates, olives, &c.	500,000
	1,200,000 feddâns.

The remainder of the land in cultivation, amounting to 2,800,000 feddâns, is either appropriated to the raising of grain or to the purposes of horticulture. The total quantity of corn annually produced in Egypt has been estimated at three millions of ardebs, or six millions of quintals. Besides this, the country furnishes nitre, salt, natron, and soda; and about two hundred thousand ox and buffalo hides are annually collected for exportation. If to these products, then, be added the amount of the duties levied on industry and commerce, the gross return for all Egypt may be estimated at 68,600,000 great piastres, or L.14,500,000 sterling. According to this calculation, the net revenue of the viceroy ought to be 25,000,000 great piastres, or L.5,248,000 sterling; but if due allowance be made for contingencies, and if we take into account that this revenue is raised by means of extortion on the one hand, and monopoly on the other, we shall not probably err in making an abatement of 5,000,000 piastres from the nominal amount, and estimating it at L.4,000,000 sterling. Egypt has also woollen, cotton, linen, and silk manufactures, some few of which were in a state of considerable activity even before Mehemmed Ali introduced his new system; but notwithstanding the powerful stimulus which the viceroy has given to the industry of his subjects, and the great improvements which have thence resulted, it is manifest that, in manufactures, it is vain for a people situated like the Egyptians to attempt to compete with the capital, machinery, and skill of Europe; more especially as the nature of their climate, and the extreme fecundity of their soil, will always enable them to make advantageous exchanges, and to purchase superior articles at much less cost than inferior ones can be manufactured in their own country. The true policy of Mehemmed Ali is therefore to abandon entirely the system of monopoly to which he has hitherto clung with such blind tenacity; to render commerce perfectly free; to abstain religiously from interfering with the circulating medium, the alterations in which have hitherto been productive of so much evil; and, above all, to encourage and promote agriculture, which must ever remain the grand source of wealth to a country which, possessing a fertile soil, enjoys constant sunshine and the means of perpetual irrigation.

With all his defects, however, Mehemmed Ali, if he has not outstripped his age, is at least prodigiously in advance of the people over whom he rules; and he is disliked by the more influential classes of his subjects for those very qualities which have raised him so high in the estimation of Europe. The indulgence which he has granted to religious sects of every denomination; the introduction of vaccination, and other improved surgical practices borrowed from Europe; and, above all, the establishment of a school of anatomy, where the waxen models procured from Italy have at length been superseded by actual dissections; these are innovations which have shocked the prejudices and alarmed the ignorance of the bigoted and fanatical Moslemins. But Mehemmed, who in fact appears only to be a Turk among Turks, is not a man to be deterred from the pursuit of objects the accomplishment of which he foresees will be productive of great and certain advantages; and by his admirable management, combined with the outward observance of the rules of Islamism in his own person, he has overcome difficulties and surmounted obstacles which would have altogether appalled any ordinary man. Accordingly, whilst he has embellished mosques, decorated fountains, constructed reservoirs, and erected colonnades in honour of saints, for the gratification of the faithful, he has at the same time executed works of great public utility, some of which are calculated to confer lasting benefits on the country he now governs, and to accelerate more and more the development of its industry.

One of the most remarkable of these is the canal of Mahmoudyeh, which connects the harbour of Alexandria with the river Nile, near Fouah, and establishes a water communication between the capital and the principal port of Egypt. This magnificent work, which was opened on the 7th of December 1819, is forty-eight miles in length, ninety feet in breadth, and about eighteen feet in depth, and affords a means of conveyance by which the whole produce of the country may, without danger or delay, be brought to the place of exportation. A circumstance which occurred in 1817 first suggested to the pasha the idea of this great undertaking. In the winter of that year, when a scarcity prevailed all over Europe, multitudes of vessels resorted for grain to Egypt, where the crops had been unusually abundant; but owing to the difficulty of the bar at the Rosetta mouth of the Nile, and the tempestuous weather which prevailed along the coast, little or none of it could be conveyed in time to Alexandria; and hence, of about three hundred vessels which had assembled at that port, some were obliged to return in ballast, whilst others sailed with only half cargoes. This circumstance, which occasioned a heavy loss, and produced numerous disputes amongst the agents and merchants, suggested to the pasha the advantage of having a navigable canal to connect the main branch of the Nile with the port of Alexandria; and with his usual energy and decision he resolved to proceed as soon as possible with the undertaking. For this purpose he caused all the labourers in Egypt to be put in requisition, and a month's pay to be advanced, in order to enable them to provide necessaries; and to each village he allotted the extent of work which, it was expected, they were to perform. The Arabs, under their respective chiefs or sheikhs, were accordingly marched down in vast numbers to the line of the intended canal, along which they were distributed; and it is said that as many as two hundred and fifty thousand men were at one time employed at the work. The greatest Pharaoh of the olden time, including even Mœris himself, could not have

[1] Mengin, *ubi supra*. Rifaud, *Tableau de l'Egypte*, p. 24.

[2] A feddân is a land-measure equal to about one third of an acre.

acted with greater energy than was displayed by the viceroy on this occasion. The whole excavation was completed in less than two months, at the end of which time the great mass of the labourers were permitted to return to their homes; but, in the autumn, several thousands were employed in facing certain parts of the excavation with masonry, equalizing the cut throughout, and thus rendering the whole navigable for vessels of considerable tonnage. The work having been carefully finished, was opened at the time above specified; and the increase of trade at the port of Alexandria has already proved the wisdom of the undertaking, and liberally rewarded the viceroy for his exertions.[1]

The following view of the actual trade of Alexandria, extracted from the second edition of a most valuable and instructive work,[2] contains much important information, and at the same time affords conclusive evidence of the rapidly improving state of Egypt:

" The imports principally consist of cotton stuffs, timber, hardware, iron and tin, tobacco, machinery, ammunition, silk goods, woollen staves, &c. The exports consist of raw cotton, wheat and barley, rice, linen, flax, linseed, sugar, coffee (from the Red Sea), drugs, gums, sal-ammoniac, saffron, wax, &c.

" The principal articles of importation into this country from Egypt are cotton, flax and linseed, senna, and gum. Of these, cotton is by far the most important. We began to import it in 1823; and since then the imports have been as follows:

Years.	Bales.	Years.	Bales.	Years.	Bales.
1824	38,022	1827	22,450	1830	14,752
1825	111,023	1828	32,889	1831	38,124
1826	47,621	1829	24,739	1832	41,183

" In 1832, the French imported 25,807 bales of Egyptian cotton; the imports at Trieste during the same year were about 50,000 bales, and those at Deghorn and Genoa were together about the same as at Trieste. The bale of Egyptian cotton weighs about 220 lbs. This important trade owes its existence almost entirely to the exertions of the pasha, by whom the cotton plantations have been established. The cotton exported is all long-staple, but of two sorts; one called in Egypt makko, and in England common Egyptian; the other, the produce of sea-island seed, called in Egypt Sennaar, and in England sea-island Egyptian. Besides these two descriptions, Egypt produces from 15,000 to 20,000 bales of short-staple cotton, similar in quality to that of Smyrna, and chiefly consumed in the country. The cotton brought from Egypt is found to be amongst the most useful that is grown; that raised from sea-island seed ranks next to American sea-island. The exports from this country to Egypt principally consist of cotton goods and twist, earthenware, iron and steel, arms and ammunition, &c. Their *real* value amounted in 1831 to L.122,832; but besides what goes direct, a good deal of British produce finds its way to Egypt at second hand from Malta, Smyrna, &c. Constantinople and the islands of the Archipelago are the great markets for the wheat and other grain exported from Egypt, the quantity sent to them being sometimes very large. The supplies are, however, extremely uncertain. Every thing in Egypt depends on the Nile; and when it does not rise to the usual height, the crops are very much below an average. Beans are extensively cultivated, and have sometimes been brought to England, but rarely, if ever, with advantage to the importers. They are very inferior to English beans, and are peculiarly subject to the worm. No oats are raised in Egypt, the horses being entirely fed upon barley. Besides cotton, the pasha has turned his attention to the culture of sugar, indigo, &c. The first has long been raised in Egypt, but the exports are not very considerable. Silk is grown to some extent. The date-palm thrives in every part of Egypt, and the fruit is largely exported. It is singular, that notwithstanding the luxuriance of many of its vegetable productions, Egypt should be entirely destitute of timber.[3]

" In 1831, there entered the port of Alexandria 1215 ships, of the burden of 198,299 tons. Of these the Austrian were the most numerous; next the English and Ionian; and then the French, Sardinian, Spanish, &c.

" *Money.* Accounts are kept at Alexandria, as at Cairo, in *current piastres*, each piastre being equal to 40 paras or medini, and each medino to 30 aspers. The medino is also divided into 8 borbi, or 6 forli. A purse contains 25,000 medini. The piastres struck in 1826 contain a great deal of alloy; 15½ or 16 piastres = 1 Spanish dollar; hence 1 piastre = 3½d. sterling, very nearly. Payments in transactions of any importance are generally made in Spanish dollars.

" *Weights and Measures.* The yard, or *pik*, = 26·8 English inches; hence 100 piks = 74·438 English yards. The measures for corn are the *rhebebe*, and the *quillot* or *kisloz;* the former = 4·364 English bushels, the latter = 4·729 ditto. The *cantaro* or *quintal* = 100 *rottoli*, but the rottolo has different names and weights: 1 *rottolo forforo* = ·9347 lb. avoirdupois; 1 *rottolo zaidino* = 1·335 lb. ditto; 1 *rottolo zauro* or *zaro* = 2·07 lbs. ditto; 1 *rottolo mina* = 1·67 lb. ditto.[4]

" *Duties.* With the exception of the commercial monopolies of the pasha, and the arbitrary principles on which he fixes the prices of commodities, there is nothing objectionable in his policy as to commerce. The duties on imports are only three per cent. We believe, however, that a small increase of the customs duty would compensate the pasha for the abolition of most of his monopolies; and there can be little doubt that his subjects would be materially benefited by the change."

---

[1] The arbitrary energy displayed by the pasha in the construction of this great work in so short a space of time could scarcely be unattended with much suffering, and even a considerable mortality; but the statement of some writers, that twenty thousand labourers fell a sacrifice to the unsparing urgency of the viceroy on this occasion, is a manifest exaggeration. The advance of a month's pay must have enabled the workmen to repair to the intended scene of operations without much inconvenience; and the liberal remuneration they received while employed in excavating the canal must have afforded them better subsistence than they can ordinarily command. If any extraordinary mortality occurred, therefore, it must have fallen, not upon the labourers, but upon the crowds of women and children, who, as in the patriarchal times, accompanied them to the neighbourhood of Alexandria. This practice, which it has been found impossible to check, has been attended with great inconvenience in other cases, particularly in that of the military conscription. In the year 1827, twelve thousand recruits being wanted for the army, were, as usual, taken by force from their villages; but when these conscripts appeared at the camp near Cairo, they were attended by upwards of fifty thousand followers of all ages and both sexes, who, of course, must have suffered great privations before they could return to their miserable, and, in many cases, distant homes. Something of the same kind may, no doubt, have occurred at Alexandria, on the occasion referred to. But whilst it is inconceivable that any such mortality as that above stated could have taken place amongst the labourers employed, it is highly probable that their followers may have suffered severely; and, as the Franks are accused of having suggested the undertaking, the current story is believed, partly because it affords a pretext for throwing upon a race otherwise hated for their superior intelligence, the odium which naturally enough attaches to the remembrance of an oppressive servitude.

The increase of trade which is here shown from recent and authentic documents has been the result of the zeal, energy, and perseverance displayed by the viceroy. But accident also contributed to promote his success. A Frenchman named Jumel having one day discovered in the garden of a Turk a plant of the cotton-tree, immediately turned his attention to the subject of its cultivation, and in a short time propagated it with so much success that the discovery of this plant may be considered as having changed the commerce and statistics of Egypt. So rapid was the progress made that, in a few years, the same individual who had discovered the solitary specimen just mentioned, and who had made the government acquainted with its manifold uses, both as an article of domestic manufacture and of foreign trade, erected at Boulak, near Cairo, a large establishment for spinning, weaving, dyeing, and printing cotton goods, and introduced the latest improvements in machinery which had been made either at Rouen or Manchester, including, we believe, power-looms. In this extensive manufactory, which is formed on the model of the best establishments of the kind in Europe, steam is the principal moving power employed, and the whole is lighted up with gas prepared for the purpose on the spot. At Siout there is also a cotton manufactory, which, not long ago, was in full operation, affording employment to eight hundred men and boys, who earned ten, fifteen, twenty, or thirty paras, and sometimes three piastres, a day; and similar establishments were about to be erected in other parts of Egypt.[1] The principal difficulties experienced arise from this, that during the prevalence of the desert winds, which are charged with an impalpable sand, the machinery is liable to be disordered by the dust which then fills the air, and penetrates into the wheel-work and finer parts of the mechanism, disturbing and sometimes altogether stopping the movements; whilst, owing to the excessive dryness of the atmosphere, the wood-work is apt to get warped or rent, and the threads, becoming brittle, snap asunder with the least tension. But these disadvantages are in some measure compensated by the cheapness of labour in a country where the people, often in a state of famine, are obliged to be content with a scanty and miserable existence, and where the supreme ruler is directly interested in keeping down wages to the lowest possible point. In fact, it is only by this grinding and oppressive system, which renders labour in the cotton factories of Egypt one of the worst kinds of slavery, and but little preferable to that imposed by the Spanish conquerors of South America on the unhappy natives, that the viceroy can ever hope to compete with the manufacturers of Europe, or to undersell the merchants of India. Whenever the wages of labour in Egypt shall, from whatever cause, experience a rise, and the master manufacturer is no longer backed by absolute power, the whole fabric, which has been reared at an enormous cost, will fall to pieces of its own accord, and the dilapidated state of the cotton factories on the banks of the Nile will present to the eye of the traveller another practical proof of the absurdity of all attempts to force manufactures in a country where population can only be profitably employed in the cultivation of the soil.

The cotton now produced in Egypt is of a very superior quality to that which was formerly grown in the country, and the wool is considered as little if at all inferior to the best American. In the year 1822 the crop yielded nearly six millions of pounds; and a portion of it, sent to Liverpool on trial, was sold at the rate of a shilling a pound. The produce of the crop of 1823 was still more abundant; so much so, indeed, that, after supplying the demand in the ports of the Mediterranean, about fifty thousand bags were exported to England. This auspicious commencement only served to stimulate the energy of the viceroy. Tracts of ground long neglected were brought into cultivation, by clearing out the old canals and digging others for the purpose of irrigation; new species of cotton plants were obtained; improved modes of culture were adopted; the quality of the article was ameliorated in proportion as the quantity raised was increased; and so greatly has this branch of industry been extended, that the amount of cotton imported into this country from Egypt will at no distant period equal, if it do not exceed, that imported from America. In the culture of the cotton plant, indeed, the former country has a decided advantage in its favour. For, on the banks of the Nile, the crop is not exposed to the premature frosts and heavy rains, by which it is frequently injured in the more variable climate of the United States. In Egypt, an annual renewal of the soil, irrigation, and sunshine, are certainties; and as the accidents to which it is exposed are fewer, the supply must be proportionally less precarious.

Nor has the raising of cotton engrossed the whole attention of the viceroy; on the contrary, he has bestowed almost equal care on the cultivation of silk, flax, and the sugar-cane, to which may be added indigo, safranon or safflower, and henneh, which are employed in the various processes of dyeing and calico-printing. In the valley of Tomlut, anciently the land of Goshen, a colony of five hundred Syrians has been established, for the purpose of improving the mulberry-tree and rearing silk-worms; and in the rich and beautiful province of Fayoum, the vine and the olive are again approaching that perfection which they had attained in ancient times. Tobacco is likewise cultivated to a considerable extent; but it is so indifferent in quality that none except Egyptians will use it. In a word, it is difficult to set limits to the productive powers of a country like Egypt, where heat is constant, and moisture in some measure at the command of the agriculturist; and where, besides these two great principles of vegetation, the soil is annually renewed by the deposits of the inundation. A more enlightened experience on the part of the ruler, and the enjoyment of greater freedom on that of the industrious classes, seem to be nearly all that is wanting in order to render this early abode of civilization, which is still bestrewed with the remains of its ancient greatness and splendour, one of the richest and happiest countries on the face of the earth. But, with all his thirst for knowledge and his desire to improve, Mehemmed Ali has still much to learn, or perhaps to unlearn. Having created every thing himself, he naturally regards the whole as his own property, and is therefore almost a monopolist from necessity. He is everywhere, and in everything, intermeddling, dictating, or regulating, according to principles which can have no safe application, except in such extraordinary circumstances as those in which he originally found himself; his economical views are accordingly narrow in the extreme, and, if pushed to their consequences, will prove eminently pernicious; whilst his excise and custom-house regulations are formed upon the very worst models which Europe could supply. But the time is fast approaching when he must yield obedience to the maxim *pas trop gouverner*, and when, ceasing to interfere with the private industry of his subjects, he must consent to entrust them with the guardianship of their own interests. In short, without a large share of freedom, there can be no permanent prosperity.

---

[1] Webster's *Travels*, vol. ii. p. 131.

The pasha has another infirmity, which is also peculiar to his situation and character. He is ready to embark in almost any speculation connected with foreign trade, indeed frequently insists upon doing so; but then, though in general willing to allow his partners in such adventures time to make good their reimbursements, he is by no means equally disposed to bear his proportion of the loss; so that all they obtain from him is the loan of funds and his protection. Hence the trade with India, attempted under his patronage, ruined the smaller, and shook the more wealthy houses which engaged in it. But, notwithstanding the failure of this first attempt, he is still most anxious to open an intercourse with the East, and, if possible, to re-establish that valuable traffic which was lost to Egypt through the ignorance and barbarism of its government, as well as by the discovery of the passage to India round the Cape of Good Hope. This is not only a favourite subject of speculation with the politicians of Cairo, but also engages deeply the attention of the viceroy, who, now that he has acquired Syria, and extended the frontier of his dominions almost to the Euphrates, will assuredly employ every expedient to which he can resort in order to accomplish this object.

In the meanwhile, Egypt can, either from its own produce or by means of its transit trade, supply the states on the shores of the Mediterranean with wax, hides, coffee from Mokha, myrrh, frankincense, cocculus indicus, assafœtida, ivory, rhinoceros-horns, tortoise-shell, sal ammoniac, senna, tamarinds, ostrich feathers, incense, balsam of Mecca, gum arabic, gum copal, benzoin, Socotrine aloes, coloquintida, gum ammoniac, galbanum, sagapenum (from a nondescript *umbellate*), epopanax, shishm seed (*cassia absus*), spica celtica (a kind of spikenard), mahleb (dried fruit of *prunus mahaleb*), shebb or native alum, sulphur, musk, and gold dust. It also exports natron, which is less liable to spoil than artificial salts of the same description; but the extravagant price set on this article by the Egyptian government has greatly narrowed the demand, by compelling the merchants to make their returns in specie, which is done at a very considerable loss. The principal imports into Egypt are, the French cloths called mahouts and londrins, Florentine silks, scarlet skull-caps called *fez*, gold lace, blotting-paper, glass, earthenware, hardware; watches from England; and similar articles from Germany and Italy, especially the caps called *fez*. The imports are from France, England, Holland, Germany, Russia, Sweden, and the Mediterranean states; whilst the exports are produced in Egypt, India, Arabia, Abyssinia, Nubia, Sennaar, and Kordofân. The commodities imported from Europe indicate not only an increase of wealth amongst the subjects of Mehemmed Ali, but also considerable progress in taste and refinement.[1] We have not been able to ascertain the actual rates of the import, export, and transit duties; and the tables of Mengin, which reach no later than 1821, are already antiquated.

The intercourse by land with the countries to the south and west is carried on by means of kafilas or caravans. Those from Sennaar and Darfûr usually arrive in September or October, and depart as soon as they have sold their goods and completed their purchases. The sacred caravan of pilgrims bound to Mecca reaches Egypt about the time of the Ramadan, or Mahommedan lent, and sets off immediately after the commencement of the Beïram, or Mahommedan carnival, in order that it may reach the holy city before the month of the festival (*ahh'l hijjah*) has expired. In March and October caravans from Mount Sinai bring dates and charcoal; from time to time small caravans arrive from the Oases, laden with dates; and when the ships from Djidda reach Suez, the same mode of conveyance is employed to transport their cargoes, consisting of the products of Arabia, Persia, and Hindustan, to the capital of Egypt. The caravans from Abyssinia, which travel northward through the desert east of the Nile as far as Esneh, bring ivory, ostrich feathers, and slaves of both sexes, destined for Cairo, the place where sales of live human stock are usually effected; and they carry back, as a sort of return cargo, manufactured articles of Venetian glass, woollen dresses, cotton and linen stuffs, shawls, and some other commodities purchased at Siout and Kenneh. The Ababdeh and Bicharis tribes also descend to Esneh, where, in exchange for metals, utensils, and grain, they give slaves, camels, and the gum which they gather in their deserts, as well as the charcoal which they prepare from the acacia trees; but the most valuable commodity they import into Egypt is senna, which they collect in the mountains between the Nile and the Red Sea, where it is produced without culture. The trade of Cosseir, a port on the western shore of the Arabian Gulf, is now only a trifling remnant of that commerce by which Egypt was once enriched. The exports consist of wheat, barley, beans, lentils, sugar, flowers of carthamon, lettuce oil, and butter; the imports are coffee, cotton cloth, Indian muslins, English silks, spices, incense, and Cashmere shawls.

The custom-house duties are, upon the whole, moderate. European goods pay an import duty of three per cent.; but Turkish produce is charged five per cent. at Alexandria, and four per cent. at Boulak, the port of Cairo. For goods brought by land from the interior nine per cent. is exacted in one payment. The export duty is three per cent. to Europe, and five per cent. to Turkey;[2] but goods sent by the Red Sea pay ten per cent. each way. Every camel-load from the Saïd, or Upper Egypt, pays twenty-five piastres, or seven shillings, at old Cairo; slaves are charged twenty-seven piastres, or nine shillings a head, at Deraweh, and six piastres twenty paras, two shillings, at Cairo; ivory pays fifty piastres, or seventeen shillings, per quintal (*cantar*), and five at Cairo; rhinoceros-horns are charged ten per cent. *ad valorem*, and again at Cairo; gum arabic pays sixteen piastres, five shillings, per quintal, and twenty paras per pound; tamarinds and natrons are charged six piastres thirty paras, two shillings and three pence, per quintal, and six piastres at Cairo; and white ostrich feathers pay six piastres, two shillings, black one piastre, between three pence and four pence, per rotl, and ten per cent. *ad valorem* at Cairo. Of the latest fiscal arrangements of the viceroy consequent on the great accession of territory which he obtained from the Porte as the price of the pacification which followed the victory of Koniah, no authentic information has yet reached us; and this is not a subject which admits of conjecture or speculation.[3]

---

[1] See *Tableau du Commerce de l'Egypte avec l'Europe.*

[2] All goods sent from Damietta to Syria used to pay two per cent. additional; but since the latter country has been ceded in full sovereignty to Mehemmed Ali, this duty has been withdrawn.

[3] In Mengin's work, already so often referred to, and also in the *Tableau du Commerce de l'Egypte*, are contained very full details respecting the exports and imports of Egypt; but in the former the tabular returns do not come farther down than the year 1821, and

The revenue of Egypt in the year 1821 was estimated at L.2,249,379, derived from various sources, as, first, the miri or land-tax; secondly, the customs; thirdly, the resumed lands, comprehending nearly the whole of the cultivable soil; fourthly, the conquered territories, namely, Darfûr, Sennaar, Nubia, and part of Arabia; fifthly, the monopoly of Egyptian commerce; and, sixthly, an excise on provisions. But from the more recent data furnished by Rifaud and others, it may be inferred, as already stated, that the actual revenue of the viceroy, exclusively of that which may be derived from his recent territorial acquisitions, cannot fall much short of L.4,000,000 sterling; whilst, on the other hand, if these be included, and if the resources of Syria with its dependencies, and of the island of Candia, be taken into account, there can be little doubt that in a few years hence it will be augmented to five, six, or even seven millions sterling; a sum not more than sufficient for the support of the establishments which Mehemmed has created, and of late so greatly extended. The expenditure of Egypt in 1821 was calculated at L.1,757,840; thus leaving a surplus of income, after defraying all charges, of more than half a million sterling. But when we call to mind that, since the period to which this estimate applies, the viceroy has created a regular army amounting to between 70,000 and 80,000 men; that he has acquired a fleet of twelve sail of the line, besides frigates and smaller vessels; and that all his other establishments must have been increased on a scale of proportional magnitude, we must at once perceive that such an estimate can have no application to the present time. Of the above sum, however, upwards of one third was required for the support of the armed force, the erection of barracks, and the purchase of arms; about L.90,000 was remitted to Constantinople in name of tribute; a sum of L.14,000 was devoted to the support of the church and the law, and nearly as much expended on the pilgrimage to Mecca; and the remainder, amounting to about L.200,000, was required for the support of the viceroy's household, including his guards and yeomen of the palace. Formerly the revenue of Egypt passed through the hands of the Beys, who, after charging it with the expenses of government, were theoretically understood to remit the surplus to Constantinople. But, practically, no such remittance was almost ever made; for the different agents and collectors generally contrived so to manage matters that the expenditure overbalanced the income, and thus the Porte, instead of receiving any portion of the produce of the taxes, was frequently called upon to pay for the repairs of buildings and canals, which, as may readily be supposed, were never executed. Whilst the Mamlukes had the ascendency, they extorted, publicly and privately, about a million and a half annually; but when the French were in possession of the country, the imposts varied from year to year according to the state of the war, averaging upon the whole about nine hundred thousand pounds sterling.[1]

There is the best reason to believe that, anciently, Egypt was much more densely peopled than at present. This fact, attested by all the ancient historians, may likewise be inferred from the monuments by which the Pharaohs sought to perpetuate the remembrance of their greatness, and still more from the works by which they endeavoured to extend as well as to maintain the productiveness of the soil. Where food is abundant, population seldom fails to increase in rapid progression; and, on the other hand, where population is already pressing on the means of subsistence, the policy of nations so circumstanced is naturally, or we might perhaps say necessarily, directed towards augmenting the absolute quantity of food. At a very early period Egypt appears to have passed through the former and to have entered the latter state; whilst every fact mentioned in history, and every circumstance of real evidence supplied by the monuments still extant, conspire to prove that the ancient population of the great valley of the Nile exceeded its present amount in the proportion of nearly three to one. Before the Persian conquest, the inhabitants of all classes who acknowledged the authority of the Pharaohs were estimated at seven millions; nor, when we consider the natural fertility of the soil, and the extensive system of artificial irrigation employed at once to increase its productiveness and extend the limits of cultivation, will this calculation appear exaggerated or improbable. Besides, it is certain that the desert now covers large tracts of soil which were anciently under cultivation, and which even yet might perhaps be reclaimed from the wilderness by means of canals for the purpose of irrigation derived from the upper sections of the Nile.[2] At present the population of Egypt, divided and classed as already stated at the commencement of this section, is thought not to exceed two millions and a half; but this number, being apparently restricted to the inhabitants of towns and villages, together with such of the peasantry as are subject to taxation, does not apparently include the Arabs who occupy the deserts between the Nile and the Red Sea; and hence we shall probably be nearer the truth if we estimate the actual population of Egypt, all classes included, at three millions. No census has ever been taken of the inhabitants of this country; but as the number of houses has been ascertained for the purpose of taxation, Baron de Sacy, Mengin, and others, proceeding on this ground, and reckoning eight persons to a house in Cairo, and four in the provinces, have arrived at the following results:

	Houses.	Inhabitants.
In Cairo there are	25,000 and	200,000
In Alexandria, Rosetta, Damietta, Old Cairo, and Boulak, which are estimated at the same rate as the capital, there are............	14,532........	58,128
In fourteen provinces, containing three thousand four hundred and seventy-five villages.........	564,168......	2,256,272
Total...........	603,700...	..2,514,400

But, as already stated, this estimate does not appear to include the Arabs who inhabit so considerable a part of the country.

In a country like Egypt, the inhabitants of which are composed of so many different races, each professing a separate creed, there must necessarily exist a correspond-

---

the latter contains little or no information of a subsequent date. The same observation also applies to the general statistics embodied in the *Histoire de l'Egypte sous le Gouvernement de Mohammed-Aly.* But as Egypt, during the last ten or eleven years, has made more rapid advances than some countries do in a century, we have for this reason abstained from loading our pages with details which, however accurate with reference to the time when they were prepared, would nevertheless convey a very imperfect notion of the progress in industry, commerce, and the arts, which has actually been made within the last few years.

[2] As the present viceroy has already caused an extensive cut to be made near Elephantine, in order to avoid the inconvenience and danger occasioned by the Cataracts, it seems highly probable, if he live, that he will make an attempt of the kind hinted at in the text.

ing diversity of customs and manners. The habits of the Turk, for instance, easily distinguish him from the Mamluke or the Bedouin; the Copt can never be mistaken for the Jew, nor the Syrian for the Greek; and the wild tribes of the upper country have also each their peculiar modes and habits of life. But amidst all the diversity by which the different races are distinguished, many points of resemblance may also be detected; and the principal features of the oriental character are nowhere more strongly marked than in Egypt. It is impossible indeed to live long in any country without yielding in some degree to the influence of its national character; and though the individuality of race may still be preserved with sufficient distinctness to be easily recognised, yet all classes will be found, on examination, to have received strong impressions from the predominant modes. Our present object is to endeavour to verify by a few examples the truth of this observation.

The condition of women in Egypt is much the same as in all other oriental countries, particularly those where Islamism prevails. They are for the most part kept in a state of strict seclusion; and in this the Copts imitate the Moslemins. When they go abroad or receive visits they are always veiled. A piece of cloth, varying in texture according to the rank of the individual, covers the head and face, allowing only the eyes to see and be seen through apertures provided on purpose. This usage is of very ancient origin, and is so intimately associated with the idea of female modesty, that it is never dispensed with excepting in very peculiar circumstances. "When any of the Egyptian women," says Napoleon, "found themselves by accident surprised without their veils, and covered only with that long blue shift which forms the clothing of the Fellahs' wives, they used to take up the lower part of the shift to hide their faces, preferring the exposure of any other part."[1] Amongst the orientals, wives are sacred; and hence, in their intestine wars, the latter are always respected. Whilst the Mamlukes, for example, were carrying on war against the French, their wives remained at Cairo. Women decay very early in Egypt; and there are more of them brown than fair. In general their faces display a little complexion, but the predominant hue is a light and transparent bronze. The most beautiful are either Greeks or Circassians, and with the latter, particularly, the bazars of the merchants who deal in female slaves are for the most part abundantly provided. The Ethiopian women brought to Egypt for sale by the caravans from Darfûr and other parts of the interior, though jet black, are exceedingly beautiful; their features being perfectly regular, and their eyes full of animation. The Circassians are more highly prized by the orientals than the Europeans, who, having formed their standard of beauty on different models, are at a loss to reconcile the specimens they have actually seen with those high-flown descriptions which fill the pages of eastern romance, and attribute all the charms of female loveliness to the natives of one favoured spot on the Persian side of the Caucasus.

Marriage takes place amongst the Moslemins without either party having ever seen the other, excepting by accident. This results from the seclusion in which females are kept throughout the whole of the East. Sometimes, indeed, the bride may have seen the bridegroom, but the latter can never have beheld his betrothed, or at least the features of her face, and for her charms and qualifications must therefore depend entirely upon report. Marriage, in fact, which is always negociated by the elder females of families, is merely a civil contract prepared by the mutual friends of the parties, and signed by the bridegroom and his guardian. Amongst the Copts, who are even more rigid than the Moslemins in the seclusion of their females, matrimonial alliances are contracted in a similar manner, and have precisely the same character. The ceremonial usually observed in both cases has often been described, and need not therefore be repeated in this place.[2] Mahommedan wives have certain privileges, of which they are very tenacious, and which their husbands cannot refuse them without passing for brutes and barbarians, and enraging every body against them. Of these, the principal is that of going to the bath, which may be described as the women's coffee-house. Thither they repair as often as they feel inclined, and the bath is the place where political and other intrigues are contrived, and where marriages are planned. But, notwithstanding this indulgence, they feel deeply the restraint under which they are kept, and, from all that can be learned, would willingly conform to the Frank customs, if permitted to do so. Where women are excluded from society, refinement of manners must be wholly unknown. In the house of an Osmanlee, the apartments allotted for the women are generally furnished with the richest and most expensive articles; but those of the men are remarkable only for a plain style of neatness.

The dress of the orientals bears no resemblance whatever to ours, and is in all respects more ample and voluminous, allowing greater freedom of motion and exertion. The turban is a much more elegant and convenient headdress than a hat; and being susceptible of great variety in form, colour, and arrangement, discovers at the first glance the differences of nations and ranks. As the neck and limbs are not confined by bandages or ligatures, a native of the East may remain a month in his clothes without feeling fatigued by them. The different races and classes are of course differently dressed; but they all agree in wearing papooshes or wide pantaloons, large sleeves, and every other part of their dress full and ample. To protect themselves from the sun, they wear shawls; and a great quantity of silks, Indian stuffs, and cachemires, is introduced into the dresses both of men and of women; but they wear no linen. The Fellahs are covered with a blue shirt fastened round the middle. The Arab chiefs who traverse the desert during the scorching heat of the dog-days cover themselves with shawls of all colours, which they also wrap round their heads, and thus protect the different parts of their bodies from the sun. Instead of shoes, both men and women wear slippers, which they leave on the edge of the carpet when they enter an apartment.[3] It ought to be mentioned, however, that, since the military changes introduced by the present viceroy, European modes have been gradually gaining ground, and that even the dress on which the Osmanlee not un-reasonably prides himself is in some danger of experiencing some curtailments and abridgments little calculated to improve its picturesque effect.

---

[1] *Memoirs*, vol. ii. p. 274. When Napoleon was in Egypt, he had several opportunities of seeing some of the most distinguished women in the country, to whom he granted audiences. "These were either the widows of beys or kiachefs, or their wives, who, in their absence, came to implore his protection. The richness of their dress, their noble deportment, their little soft hands and fine eyes, a dignified and graceful carriage, and very elegant manners, distinguished them as women of education and rank superior to the vulgar……Many of them stated their requests with perfect grace, and an enchanting tone of voice, displaying all the intelligence and sweetness of the most accomplished women of Europe. The propriety of their demeanour, and the modesty of their dress, gave them additional fascinations; and the imagination delighted in guessing at charms of which they did not even allow a glimpse." (*Memoirs*, ubi supra.)

[3] Napoleon's *Memoirs*, vol. ii. p. 278, 279.

When the French occupied Egypt, there was neither coach nor cart in the country, excepting one which Ibrahim Bey had received from France, and which was accounted a very remarkable thing. Water-carriage being so abundant and easy, coaches and other vehicles are perhaps less necessary there than in any other country of the world. Horses are used for traversing the capital by all except women and lawyers, who, being apparently considered as equally effeminate, ride on mules or asses, surrounded by their attendants.[1] When women have occasion to travel any distance, they are usually conveyed in panniers placed on the backs of camels. There is an immense quantity of asses in Egypt; they are large and of a fine breed, and at Cairo they in some measure supply the place of hackney coaches. In the capital no one in the Frank costume dares to appear in the streets on horseback. The style of living is much the same as that which prevails generally throughout Turkey; but as the viceroy, notwithstanding the prohibition in the Koran, does not scruple to drink wine, his example has introduced some degree of laxity into the manners of the capital, where there are many persons disposed to think that the practice of the pasha in this particular is entitled to more respect than even the prohibitory injunction of the Prophet. Among Europeans, however, who are under no restraint of any kind as to their mode of living, all sorts of indulgences are common; and at their tables may be found the most *recherchés* efforts of foreign cookery, garnished with the wines of Europe and the fruits of the East. Nor is it likely, now when the intercourse between them and the Turks is much more frequent and intimate than formerly, that their example can be without effect upon their guests and visitors; more especially as it is evidently the policy of the viceroy to break down Turkish customs, and to destroy the attachment of his countrymen to those modes and habits which have so powerfully contributed to keep them in ignorance, and nurse a spirit of intolerance. As to Mehemmed himself, he labours under the imputation of being a freethinker,[2] notwithstanding all he has done for the deliverance of the holy cities; and his character in this respect has not failed to produce a marked impression upon the sentiments of the higher classes in Cairo. As the viceroy himself cares for no man's religious creed, and is content to be served by a Christian, a fire-worshipper, or a votary of the Grand Lama, as well as by the most devout professor of Islamism, it may easily be supposed that those about his person or his court will not be slack in imitating his example in neglecting such distinctions.

The festival of opening the Kalidji, or admitting the water of the Nile into the canal of Cairo, by cutting the dike or embankment raised to exclude it until the river has attained a given height, is annually observed with every demonstration of joy, and forms one of the customs which have descended from the most ancient times. In Egypt there is no subject of such general and engrossing interest as the overflow of the Nile, upon which the productiveness of the country wholly depends; and, accordingly, on the occasion in question, the sounds of festive rejoicing, intermingled with music, songs, and cries of "Allah illah Allah," are heard all over the capital. The river god, the beneficent genius of Egypt, is then pouring abundance out of his watery urn. Besides, the inhabitants of Cairo, like the populace of all great cities, are fond of pageants and shows, and, upon such occasions, amuse themselves with feats of strength and dexterity, as also with singing and dancing. Buffoons exhibit for the entertainment of the multitude, whose ready laugh responds to their stale jests and coarse pleasantries. But the almehs, or improvisatrices, who are performers of a different class, reserve the exercise of their talents for the amusement of the affluent. These females, being called in to relieve the solitude of the harem, teach its inmates new airs, repeat verses or poems, initiate the Egyptian ladies in the mysteries of improvisation, and perform dances, which are often of a very unbecoming and lascivious character. Some of these women, however, are persons of cultivated minds and agreeable conversation; they perform their recitations with considerable effect, and possess a great command over their native language, which they speak with purity and grace. The practice of hiring women to utter lamentations for the dead is still observed at Cairo, to the great annoyance of the Frank population, who detest the doleful howlings of these professional mourners. In the capital, and also in some of the large towns, charmers of serpents occasionally exhibit their extraordinary feats, to the amazement and horror of the bystanders, brandishing live reptiles of the most poisonous description, and then tearing them with their teeth. But the practitioners of this perilous art do not always escape with impunity.

A printed book was a rare sight in Egypt until Mehemmed Ali introduced, along with other improvements, an European press, and founded a printing establishment. A class of men, similar to the copyists and caligraphers of the middle ages, earned a subsistence by making transcripts of the Koran, the Arabian Nights, and other works in demand, some of which were beautifully executed in inks of various colours.[3] But the occupation of these artists is now in a great measure gone, and the penman will soon be altogether superseded in such work by the compositor. In fact, the publication of a newspaper was some time ago commenced under the auspices of Mehemmed Ali; and although the *Egyptian Moniteur* does not enjoy, and indeed cannot be permitted to exercise, that freedom of speculation and boldness of remonstrance for which the press is distinguished in the free countries of Europe, yet it is apparently more unfettered than most of the journals in Germany, and contains much useful information respecting the remoter parts of the Egyptian dominions, as well as in regard to the improvements from time to time introduced with a view to continue the movement in advance which has already been communicated by the viceroy to almost all classes of the people under his sway.

In contemplating the improvements which have already been effected in Egypt, and the still more extensive and complete renovation which that country seems destined to undergo from the combined operation of the various causes presently at work, it is impossible not to be struck with admiration of the man by whom alone all these wonders have in fact been achieved, and who has written his name in such indelible characters upon the face of the interesting land where he has laid the foundations of a new empire. Comparing Egypt as it was at the commencement of the present century with its actual condition as described in the latest accounts which have reached us, we could almost persuade ourselves that, instead of thirty years, we had passed over three centuries, and that the striking contrast which is thus presented must be altogether unreal, a creation of oriental genius in its most imaginative mood, rather than the work of a mere human agent wholly unprovided with supernatural means. Anarchy has given place to order, and violence to the empire of the law. Arabs, Turks, Mamlukes, and Albanians have all been reduced into the most complete subjection to a government which has arisen from a chaos of discordant elements, and out of these gradually formed the "fair state," which is perhaps destined to become the centre of a new system of civilized nations. At the period of his accession to power Mehemmed found the soldiery mutinous and disorganized, the finances exhausted, property insecure, agriculture neglected, commerce annihilated; and, surrounded by ignorance, cruelty, treachery, and fanaticism, he knew that he could not attempt to advance a step except at the hazard of his life. Yet, endowed with invincible energy and perseverance, he has surmounted all obstacles, and compelled every class and order of men to yield implicit obedience to his government; and even in the depths of the Arabian desert he is feared and obeyed. Having destroyed a licentious and ungovernable militia, he has created a powerful army, which is controlled and governed by a stern system of discipline; his finances are in the most prosperous condition; new articles of produce have been raised; agriculture in all its branches has been improved and extended; works of the greatest magnitude and importance have been executed; commerce is carried on to an extent formerly unknown; ample security is afforded both to person and to property; and that confidence which is the first condition of prosperity universally prevails. From Alexandria to Assouan the road is as open and the security as complete as in the most civilized nations of Europe; at the Cataracts as well as at Cairo the traveller may repose in peace. But the moral change which he has wrought is much more extraordinary than all his military, political, commercial, agricultural and other improvements put together, and will, in its consequences, be productive of results still more important to the cause of civilization. He has attacked bigotry and fanaticism at their very source; and by frowning down ignorance, and letting in perforce the lights of knowledge amongst his subjects, he has done more to subvert the empire of a creed essentially adverse to human improvement than all its declared enemies put together. That in his character many dark spots may easily be detected, it would be ridiculous to conceal, far less deny. He has both failings and vices as a ruler, which, although it would be vain perhaps to regret them, it is nevertheless instructive to point out for the benefit of those who study human nature under all its varied aspects. But, on the other hand, these are so completely eclipsed by his great and splendid achievements in almost every field where a superior mind can display its native energy, that we may perhaps be excused for having dwelt more on the bright than the shaded part of his character.[1]

---

[1] An Egyptian lady mounted on a mule or an ass, and wrapped up from head to foot in a black mantle, has not inaptly been compared to a coffin placed upright on a saddle and covered with a pall.

[2] The celebrated Sheikh Ibrahim (Burckhardt), with whom Mehemmed was very fond of conversing, presented himself one day before the viceroy. "Pasha," said he, "I want to go and see the holy city, and pray at the prophet's tomb; give me your leave and firman for the journey."—"You go to Mecca and our blessed prophet's tomb!" said the prince; "that's impossible, Ibrahim; you are not qualified: you know what I mean: nor do I think you are a true believer."—"But I am, pasha," was the reply; "you are mistaken, I assure you; I am qualified, too, in every respect; and as to belief, have no fears about that; tell me any part of the Koran that I will not believe."—"Go to the holy city; go, Ibrahim," said the pasha, laughing heartily; "I was not aware you were so holy a man. Do you think I'll vex myself with questions from the Koran? Go and see the prophet's tomb, and may it enlighten your eyes and comfort your heart." (Carne's *Recollections of Travels in the East*, p. 248.)

SECTION V.

MONUMENTAL AND OTHER ANTIQUITIES OF EGYPT.

Plan of description.—Philæ; its temples and monuments.—Obelisk removed by Belzoni for Mr Bankes.—Importance of the inscriptions on this monument.—Elephantiné; its quarries.—Syené or Assouan.—Measurement of a degree of the meridian by Eratosthenes.—Ombos or Koum Ombo.—Edfou or Apollonopolis-Magna.—Elethya; its college of priests.—Esneh or Latopolis.—Hermonthis or Hermont.—Thebes.—Medinet-Habou.—Temples and monuments in this division of the ancien capital.—Biban-el-Moluk or gates of the kings.—Catacombs or tombs of the kings.—Discoveries of Belzoni among these *hypogæa*.—Sarcophagus of alabaster.—Kourah.—Characteristics of Egyptian architecture.—The palace of Luxor.—The temple of Karnak.—Site and dimensions of Thebes.—Origin of the name.—Kous or Apollonopolis-Parva.—Coptos or Kebto.—Ghenneh or Kenneh.—Tentyris or Denderah; its monuments and antiquities.—Planisphere or zodiac of Denderah.—Speculations to which this planisphere has given rise refuted both by the calculations of science and the dates fixed by the inscriptions.—Abydos.—Genealogical tablet discovered by Mr Bankes.—Importance of this document to the historiography of Egypt.—Diospolis-Parva.—Djirjeh.—Ikhmim, Eckmoum, or Panopolis.—Antæopolis or Kau.—Lycopolis or Siout.—Schmoum or Hermopolis-Magna.—Antinoë.—Oxyrynchus.—Heracleopolis.—Crocodilopolis.—Aphroditopolis.—Labyrinth.—Memphis.—Mechanical labours of the Egyptians.—Pyramids.—Lake Mœris.—Other antiquities.

As any attempt to classify the monumental antiquities of ancient Egypt would lead to the greatest confusion in topography, there are only two modes in which these remains can be described without creating embarrassment to the reader; namely, by taking them either in an ascending or descending order, with reference to the course of the river, on or near the banks of which they are almost all situated. But as we conceive that civilization, flowing from the interior, originally descended along the valley of the Nile, and as either method is equally conducive to perspicuity, we prefer the latter; more especially as it will bring us at once in contact, as it were, with some of the most extraordinary monuments in this land of wonders and prodigies.

Supposing, then, that we enter Egypt from Nubia on the south, and follow the course of the Nile downwards, the first place of note which occurs is the island of Philæ,[2] about six miles to the south of Syene or Assouan, and nearly thirty-four to the north of the tropic of Cancer. Occupying an area of barely nine hundred yards in circumference, and a hundred in breadth, this diminutive island nevertheless presents a variety of objects deserving of admiration, and calculated to revive a multitude of historical and classical recollections. Independently of other considerations, the etymon of its name affords presumptive evidence of the remoteness of the period at which this celebrated spot first formed the southern boundary of Egypt, or, as it were, the Nubian gate of the kingdom of the Pharaohs. But being considered as the burial-place of Osiris,[1] and adorned with temples, one of which was believed to have been erected by Isis in honour of her husband-brother, it has higher and more interesting claims to our attention; and as every thing which antiquity or sanctity could offer to warm the imagination or kindle the devotion of the votary seemed concentrated on this hallowed islet, it had accordingly become a favourite place of pilgrimage among the worshippers of Osiris at a period long anterior to the commencement of history. One of the names by which it is at present known, Djeziret-el-birba or the Temple-Island, sufficiently indicates the character and the magnitude of the ruins with which it is covered; ruins which the neighbouring Arabs denominate Anas-el-Wojud, or the sociality of Wojud, who, according to their traditions, built these palaces as a retreat to which he might betake himself for the purpose of social or convivial enjoyment.[2] Though the surrounding cliffs are of a dark-brown granite, the temples are all built of a bright white sandstone; and nearly the whole island is cased with walls of hewn stone, forming quays concave towards the stream, but convex towards the land, which give it the appearance of a modern escarpment.[3]

---

[1] In effecting his improvements, Mehemmed had not to contend with a privileged aristocracy, inheriting historical names, and intrenched behind the prejudices of centuries. The incessant revolutions of which Egypt was the theatre, and the long-continued sway of the Mamlukes, whose power was based, not on opinion, but on force, had, even amongst the Arabs, destroyed much of the *prestige* in favour of the distinctions of hereditary rank, and worked incredible injury to the science of genealogy. How indeed could it be otherwise in a country where all respect was reserved for the purchased slave, whose relations were unknown, but whose bravery or other personal qualities had raised him to the highest honours? "I have heard," says General Regnier, "both Turkish and Mamluke officers say of a person who occupied great posts, 'He is a man of the best connections; he was purchased.'" (Regnier, *De l'Egypte*, p. 68.)

[2] The Arabic name of Philæ is *Bilak*, which is merely the old Egyptian name *Pi-lakh*, signifying "the end or extremity," spelled in the Arabic fashion.

This island is entirely covered with temples in large groups, and in a high state of preservation; and from a rocky eminence at its southern extremity the whole of the ruins may be seen at once. On the south-west side are two large temples, adorned with and connected by long colonnades, but manifestly of different ages; on the right is a small temple of Isis, with an isolated, unfinished building, having no remains of the cella, nor any appearance of an interior cornice; and on the left are an obelisk, and long porticoes leading to a large temple of Isis, near a smaller one dedicated to Hathôr or the Egyptian Venus, which Champollion has pronounced the best in the island. The great temple of Isis,[4] which is the southernmost of all, has two colossal pyramidal propyla, one between the dromos and pronaos, and another between the pronaos and portico, with a smaller one leading into the sekos or adytum. But none of these propyla are in lines parallel to each other, all of them, as well as the dromos, turning from the body of the temple, each about one point towards the east; an irregularity probably owing to the form of the island or the varying state of the rocky foundation, but which renders the building exceedingly complex. None of the existing monuments of Egypt is better calculated to convey an adequate idea of the magnificence by which they are characterised than the portico of this temple, which consists of twelve columns, four in front and three deep. The capitals, which are in pure Egyptian taste, represent varied forms and compositions of the palm branch, the domm leaf, and the lotus. These, as well as the sculptures on the columns, the ceiling, and the walls, have been painted in the most vivid colours, which still retain much of their original brightness; and there is reason to believe that the same was the case in the interior of this as well as of the other temples, although the damp and the nitrous quality of the confined air have entirely destroyed the colours. One of the majestic pylons of this temple, flanked by two square, tower-like masses of masonry rising pyramidically to the height of fifty-four feet, leads to the second court, and towers above everything around, being the loftiest building on the island; and both are richly ornamented with sculpture and hieroglyphics, the number of which is immense. Three large and several smaller chambers lead to the adytum or sanctuary, in one corner of which there is a granite block, containing a niche for the bird (a kind of hawk) venerated as the emblem of Osiris, and entirely covered with hieroglyphics. Bas-reliefs, representing processions, festivals, sacrifices, and other scenes connected with the worship of the gods of Egypt, cover the walls within and without; and on the ceiling of the portico are sculptured a human figure, with a mitre on the head and a serpent in the hand, three female figures with the arms and legs extended, two canoes with paddles, two winged globes, a flying scarabœus with hands, Osiris in his boat, and two birds flying with palm branches in their claws. Fragments of obelisks and lions consisting of red granite are strewed about upon the ground in front of the temple. According to the most probable calculation, this temple was commenced by Philadelphus, continued under Euergetes I. and Epiphanes, and completed by Euergetes II. and Philometor.[5]

On the left of the great temple of Isis is an uncovered enclosure formed by a colonnade, the intercolumniations of which are filled to nearly two thirds of their height; but to make amends for this, the plinths are raised to a disproportionate thickness. This structure, which has evidently been left in an unfinished state, was by the French architects called "the eastern" or "temple of Isis," from a supposition, now proved to be erroneous, that the great temple had been dedicated to Osiris. Before it lay a small obelisk of granite, which, though displaced, had sustained but little injury. This monument, which eventually proved of so much importance in regard to the deciphering of hieroglyphics, was first noticed by Mr W. J. Bankes in 1815; and two years afterwards Mr Belzoni, acting on his account, succeeded, in spite of numerous difficulties and even dangers, in transporting it along the Nile to Rosetta,[1] whence it was conveyed to England. The hieroglyphics on the shafts and the Greek inscription on the base of the obelisk were faithfully copied under the superintendence of Mr Bankes; and when the principles of interpretation applied by Dr Young to the triple inscription on the Rosetta stone were extended to the double inscription on the obelisk of Philæ, it was ascertained that the Greek was merely a version of the Egyptian text; a discovery to which, as will afterwards be shown (see HIEROGLYPHICS), we are in a great measure indebted for the formation of the phonetical alphabet. The Greek text has been ably illustrated and explained by the celebrated French Hellenist, M. Letronne.[2] At some distance from these temples, and near the water's edge, there is a large hall, the walls of which are covered with sculptures relating to the death of Osiris; and over these are scattered inscriptions of different ages, and in various characters, recording the names of pilgrims who had visited the temple-island in order to pay their devotions to the presiding deities of the place. At the northern extremity of the island there are the remains of a triumphal arch, and other works of Roman architecture; and on the north-east side an unfinished temple, exhibiting many peculiarities of structure, and showing that the arts were not always stationary in Egypt. In a word, within the compass of this little island, Nubian cabins, Arab huts, Christian chapels, Roman fortifications, and Egyptian temples, are crowded together in such a manner as to produce a painful sense of the lapse of ages, the transitory nature of empires, and the destructibility of human works, however colossal in magnitude or solid in construction.[3]

---

[1] This honour was disputed by Abydos, Memphis, Busiris, and Teph-Osiris.

[4] To this temple, which all travellers except Champollion have uniformly spoken of with enthusiastic admiration, the *minuit præsentia famam* is fully as inapplicable as to any other monument in this land of wonders. (Hamilton's *Egyptiaca*, p. 45.) The Frenchman, however, admits that the sculpture is altogether worthy of the epoch which produced it, namely, the Greek, which he nevertheless considers as "une époque de décadence." (*Lettres*, p. 115.) In fact, he is of opinion that everything at Philæ is *modern* ("tout y est *moderne*") except the small peripteral temple of Hathôr, and a propylon connected with the first pylon, which, according to him, was constructed and dedicated by Nectanebo I. (*Lettres*, ubi supra.)

[5] The rows of lions in front of this temple, and the occurrence of the same figure among the hieroglyphs, led the French savans to conclude that this emblem was meant to mark the sign Leo, in which the sun once appeared at the summer solstice, when the inundation commenced. But the sun ceased to be in Leo at that season 2500 years before the beginning of our era; and hence M. Fourier concluded that this temple must have been built *before* that period, and *within* the limits of the 2163 years during which the sun was in Leo at the summer solstice. Similar inferences were drawn from the zodiacs found at Denderah and other places; so that "on travelling back," say the French philosophers, "for upwards of three thousand years, we can scarcely see a trace of the infancy of Egyptian architecture." (*Description de l'Egypte*, Antiq. i.) But, unfortunately for these speculations, Delambre has shown (*Nouvelles Annales des Voyages*, tom. viii. p. 389) that they furnish no data for determining the age of the buildings which they adorn; and from the style of the sculptures, particularly on the propylon, and still more from the hieroglyphic texts, the epoch of the erection of the temple must be that which we have assigned. If the Greek inscriptions over the entrance and on the walls had received the attention which they deserve, several erroneous theories would have been avoided, and the extravagant antiquity ascribed to this and other buildings would have been at once disproved. (*Encyclopædia Metropolitana*, art. *Egypt*.)
